GASTRO-INTESTINAL AND HEPATIC DISORDERS, ESPECIALLY CHRONIC GASTRO-INTESTINAL CATARRH, IN RELATION TO THE ETIOLOGY OF SOME CASES OF INSANITY.[1]

BY SAMUEL AYRES, M.D.,

PROFESSOR OF NERVOUS AND MENTAL DISEASES IN THE WESTERN PENNSYLVANIA MEDICAL COLLEGE, PITTSBURG, PA.

I THINK it is generally admitted by those who have given the subject much thought that in many cases the usually assigned causes of insanity are unsatisfactory and insufficient. Relatives or friends are generally ready with an explanation, particularly when this fits in with some preconceived idea of their own, as, for example, those much-abused causes—religious excitement, disappointment and overwork; but to the student of psychology these are too often inapplicable, if not incorrect. He feels that much is wanting to account for the phenomena witnessed, and that many links in the chain of etiology are missing; but it is not always easy to find these missing links; indeed, the subject is one beset with difficulties. On this matter of exact etiology, both the text-books and asylum reports leave much unsupplied. The list of causes is long enough, but we cannot help feeling that they are too general, and do not meet the requirements of scientific precision.

In connection with the obscure causes of some cases of insanity, it is the purpose of this paper to examine briefly into certain morbid states of the gastro-intestinal tract, of the liver, and of deficient excretion, which seem in the writer's judgment not uncommon but perhaps often unrecognized causes of mental derangement, and especially of melancholia.

In a general way, disturbances of the nervous system arising from derangement of the digestive organs have been recognized from remotest antiquity. It would be superfluous to more than refer to the well-founded connection between dyspepsia and despondency; between so-called biliousness and "the blues," or between prolonged constipation and mental dulness, drowsiness or headache. The derivation of the words melancholia and hypochondriasis sufficiently indicates that the old Grecians were acute observers and believed in such relationship. This association is so quaintly described by that inimitable writer, Sydney Smith, that I shall crave your indulgence for a few moments while I include a short quotation.[1] He says:

"Happiness is not impossible without health, but it is of very difficult attainment. I do not mean by health merely an absence of dangerous complaints, but that the body should be in perfect tune, full of vigor and alacrity. The longer I live the more I am convinced that the apothecary is of more importance than Seneca, and that half the unhappiness in the world proceeds from little stoppages, from a duct choked up, from food pressing in the wrong place, from a vexed duodenum, or an agitated pylorus. The deception as practised upon human creatures is curious and entertaining. My friend sups late, he eats some strong soup, then a lobster, then some tart, and he dilutes these esculent varieties with wine. The next day I call upon him. He is going to sell his house in London and retire into the country.. He is alarmed for his oldest daughter's health. His expenses are hourly increasing, and nothing but a timely retreat can save him from ruin. All this is the lobster, and when over-excited nature has had time to manage this testaceous encumbrance, the daughter recovers, the finances are in good order, and every rural idea effectually excluded from the mind. In the same manner old friendships are destroyed by toasted cheese, and hard salted meat has led to suicide. Unpleasant feelings of the body produce corresponding sensations in the mind, and a great scene of wretchedness is sketched out by a morsel of indigestible and misguided food. Of such infinite consequence to happiness is it to study the body."

Of course, this is known to everybody, but a more striking picture could not be presented of the effects of disordered states of the digestive organs on the mind.

To make the subject before us better understood, let us divide it into three parts. In the first, we shall consider the morbid states of the gastro-enteric canal and the liver and also other conditions favoring the accumulation and generation of those toxic agents which we believe to be a prominent cause of the mental disturbance in question. In the second, the absorption of these toxines and their effect on the brain and nervous system generally will claim our attention; and in the third we shall consider the partial retention or retarded elimination of various poisons from the economy and their further cumulative effect upon the brain and excretory organs.

Addressing ourselves to the first part, it is our opinion that chronic gastric and intestinal catarrh, with chronic indigestion in the stomach and intes-

[1] Being the Address in Mental Disorders delivered at the annual meeting of the Pennsylvania State Medical Society at Reading, Pa., June, 1891.

[1] Quoted from Brunton; Disorders of Digestion, p. 45.

tines, is the most constant and responsible cause of derangement of the nervous system. The alteration in the liver is, perhaps, chiefly that of chronic congestion with impairment of its important functions of properly transforming the products of digestion into nutritive fluid, and with deficiency in the secretion of bile.

It may be interesting to consider for a moment the probable origin of these chronic catarrhs. In many there is doubtless a strong hereditary predisposition to them, often strumous in character, which is readily developed by improper food. It is my firm belief, as it is that of others, that many of these ills begin in early childhood and even in infancy, from over-eating, and from badly-cooked or improperly-selected foods, especially hot breads, and that they are perpetuated by a continuance in this unwise course. The result is that in late childhood or early adult years, the boy or girl is a confirmed dyspeptic, mentally and physically handicapped, and illy prepared to endure the hard labor that may fall to his or her lot, or to meet the exactions of a long, rigid educational course, or to satisfy the silly ambitions of parents or teachers, who would have him or her acquire endless accomplishments. There are many other causes of these catarrhal states, but it is not my purpose to consider them here; it is with the condition that we are now chiefly concerned. This established and having become chronic, what occurs? All the functions of the stomach and intestines are of course impaired, digestion is manifestly imperfect, and being retarded is attended with undue fermentations, with putrefaction, and with the evolution of various gases. Under these favorable conditions, bacteria multiply, producing ptomaines, some toxic, some inert. Noxious gases distend the hollow viscera, interfering with peristalsis, and moreover are doubtless often absorbed into the blood. Thus after meals there are constantly present soluble foods, vitiated by myriads of microorganisms and their poisonous products, and mixed with abundant mucus and altered digestive ferments—a mass ill-fitted for absorption. This, the next step in the digestive process, brings us to the second part of our subject.

Dujardin-Beaumetz[1] in his admirable lectures on "Prophylactic Hygiene," asserts that from these putrefactive changes in the intestinal canal, the system may be poisoned in three ways: first, by the absorption of pathogenic microbes, which he terms a species of auto-infection; second, by the absorption of chemical poisons or alkaloids, formed by the action of these microbes on organic matter, viz., ptomaines, which he designates auto-intoxication; and third, by the combined agency of the pathogenic microbes and their ptomaines, which he calls toxinfections. To these I would add a fourth and a fifth, viz., by the entrance into the blood of various gases, especially sulphuretted hydrogen—a sort of intestinal sewage-poisoning, as Brunton[1] aptly describes it; and fifthly, by the retention or imperfect elimination of the various excretory products of the living cells of the organism, or, in other words, the leucomaines—a species of leucomainæmia, let us call it. Now, these toxic agents first spoken of, or many of them, along with the soluble foods, are absorbed into the blood by means of the veins and lymphatics, and thus enter the portal circulation; but it should not be forgotten that most fortunately they are not yet in the general blood-current; that that grand old organ, the liver, intervenes as a gate-keeper, as Brunton[2] terms it, and discriminates in the most impartial manner. We know that among its other important functions, the liver is a destroyer of alkaloids, and that the bile is antiseptic, thus counteracting the effects of some of these poisons before absorption. Were this not the case, as has been correctly said, we should be in danger of poisoning after every meal. On this subject Brunton further remarks:[3] "Were it not for the power of the liver to obstruct the passage of poisons and destroy them, the alkaloids formed by normal digestion or by abnormal putrefactive processes in the intestines might readily pass to the heart, nervous system and kidneys, and cause dangerous or fatal consequences."

But it is to be noted that, from the great burden thrown upon the liver and from the prolonged irritation in the stomach and intestines, the liver must in time become crippled and unable to separate all the chaff from the wheat. As a consequence there are admitted into the general circulation many microorganisms or ptomaines or gases, which produce the pernicious effects we are about to describe.

I have no doubt that at times nearly all persons suffer from mild forms or degrees of this toxæmia. Some attacks of headache, vertigo, irritability, drowsiness, insomnia, paræsthesia and various morbid thoughts and impulses are to be ascribed to the temporary absorption of some of these alkaloids or gases, their circulation in the blood and their disturbing effect on the nervous system; but usually these attacks are of brief duration. The diet is restricted and elimination facilitated by a brisk cathartic or a diuretic, and the individual speedily recovers his equilibrium with a corresponding rise of spirits; but let this state of things become almost permanent, let the blood be constantly poisoned by these morbid elements, let the liver fail in its important functions, and the

[1] Therapeutic Gazette, Dec. 15, 1883, p. 802; translation by E. P. Hurd, M.D.

[1] Brunton: Disorders of Digestion, p. 47.
[2] Ibid., p. 47.
[3] Ibid., p. 17.

catarrhal conditions become more and more aggravated, and, above all, as is almost certain to happen, let the emunctories be partially closed—is it then a stretch of the imagination to picture such a person, of neuropathic tendency, oppressed by an indescribable gloom, by insomnia or by an apathy that precludes all energetic movement, by dull and persistent headaches, by morbid apprehensions, strange thoughts, impulses or hallucinations, or finally by actual mental perversion and even suicide? It seems to me that this is not an impossibility. Indeed it does occur and I have witnessed it. There is no question but that many strictly nervous disorders are caused or excited by gastro-intestinal derangements of the character indicated. Every neurologist will admit that some of the most obstinate neuroses, some of the most persistent nervous manifestations are directly traceable to these catarrhal states or the reflex irritation to which they give rise. If this be true, is it not evident that in some persons mental instead of nervous troubles may follow from the same cause? Have we any positive knowledge in regard to the specific action of any of these toxines on the cerebro-spinal system? Let us consider first some effects of ptomaines, those alkaloids resulting from putrefaction. We shall bear in mind that some of these are composed of carbon, hydrogen and nitrogen, and others of carbon, hydrogen, nitrogen and oxygen, in various proportions, and that their number is very great. Many are perfectly harmless, but some are exceedingly toxic, and like certain drugs seem to have a special tendency to affect nervous tissue. For example, hydrocollidine, found in putrid fish, produces convulsions. Others, as midatoxine, choline and ethylene-diamine are paralyzers, having an action similar to that of curare. Indeed, many of these putrefactive alkaloids produce effects exactly resembling those of the vegetable alkaloids—atropine, hyoscyamine, cannabine, coniine, etc. Now, it is notorious that the prolonged and excessive use of any of these drugs may cause delusions, delirium or hallucinations, and if persistently administered, even mental derangement. We can readily understand how certain cells or centres of the cerebral cortex, constantly bathed in blood tinctured with these toxic alkaloids, will, according to the excitability of the cells, react to the poison, and in this reaction we venture to include those symptoms characteristic of the mental disturbance; but beyond this, in the present state of knowledge, we are unable to go. We are not yet prepared to state that such and such a form of insanity may result from such and such a ptomaine or several of them, or from such and such a microbe. I know of no researches directly bearing on this point, and regret that I have not myself been in a position to make any experimental studies; but in the etiology of ordinary insanity I believe this is the direction future investigation will take, and I have such faith in this causation, that the proposal of vaccination or preventive inoculation for some forms of this malady will not at all surprise me, and this at no distant day.

If the theory outlined be correct, it may be asked: which of these agencies is the most productive of mental unsoundness, viz.: the microbes, the ptomaines, the leucomaines or the intestinal gases? To this I would reply that probably the ptomaines and leucomaines are the most fertile sources. We know that diseases of microbic origin are more sudden in their invasion, that there is generally but a brief period of incubation, and that the attack is ushered in by pronounced symptoms; but such is not the history of the inception of melancholia. Usually there is an initial stage extending over several weeks or months. There may be improvements, then relapses, and even years may pass before a well-marked attack occurs, which, by suitable treatment, may be averted altogether. This corresponds with what we should expect from a general poisoning of the blood, and from the fluctuations liable to occur under various modifying circumstances; but there are cases of acute mania, or acute delirium,[1] the etiology of which is well explained on the hypothesis of infection, and these are the cases that we believe may be engendered by a pathogenic microbe as specific in its action as the germ of rabies or of tetanus. I may here add that recent researches tend to show that the pathological symptoms in microbic affections result entirely from the chemical poisons elaborated by these microbes; in other words, from the ptomaines, and not from the germs themselves.[2] But this does not render any less important the presence of the microbe as the prime factor. In regard to the agency of gases, especially sulphuretted hydrogen, evolved by these putrefactive changes in the intestinal tract, we have no definite information. Senator[3] "in 1868 related a most instructive case, in which the patient collapsed, and nearly died with all the symptoms of poisoning by sulphuretted hydrogen generated in his own intestines." It is possible that gases, when absorbed, not only add to the contamination of the blood, but in some cases cause special forms of intoxication of nerve-centres.

We come to the third part of our subject, viz.: the more permanent effects of the prolonged retention of these toxic elements in the blood, from deficient excretion, upon the brain and excretory organs. The *rôle* here played by that important

[1] James Hendrie Lloyd: "Acute Delirium." THE MEDICAL NEWS, January 31, 1891, p. 122.

[3] Quoted from Brunton: Disorders of Digestion, p. 47.

group of alkaloids, the leucomaines, is one of great significance. For the sake of simplifying the subject, suppose we let these leucomaines represent that great class of waste products resulting from tissue-metabolism, especially the so-called nitrogenous waste. Now, if to this class we add those substances that have passed through the liver unchanged, or only partly changed, such as peptones, the sugars, albumoses, etc., we shall have an array of toxic agents the circulation of which in the blood may be attended by the most serious results, and in my opinion often by insanity. Vaughan[1] states that Köttnitz, Furstner and others, have, in mental disease, found albumose in the urine. To differentiate between symptoms produced by these substances and those by the ptomaines proper, is, in the present state of knowledge, impossible, but under the former would fall the uric acid irritations, the lithæmias, the uræmic poisonings, the glycosurias, the peptonurias, the albumosurias, the stercoræmias, etc. Though we know little about some of these affections, we do know that a close relationship exists between at least one of them, lithæmia,[2] and mental depression. It must be obvious that the constant presence of some of these poisonous agents in the blood will lead to changes of the most decided character in the quality of that fluid, and that this alteration will affect the nutrition of every tissue. We have just seen how the nervous tissues, the most refined and sensitive of all, are first to react—in functional disturbance for a time, but finally in structural change. Doubtless, here is an explanation of some of the chronic interstitial and meningeal diseases of the brain that underlie the incurable psychoses.

Turning to inquire whether those organs suffer that are chiefly engaged in the effort at elimination which the economy is sure to institute, we find that they do. The skin is usually dry and harsh, the bowels torpid, the fecal evacuations generally scant; but, in my experience, we especially find renal disease.

In the able paper of Dr. Bennett, who last year delivered an address on "Insanity as a Symptom of Bright's Disease,"[3] numerous cases are cited in which mental derangement developed in those suffering from morbus Brightii. It seems to me that the observations then so clearly presented are in a measure supplemented in this paper; that the insanity apparently resulting from "uræmic poisoning," *i. e.*, from insufficient excretion of waste products in those having renal disease, is not primarily due to this cause, but that the blood, being vitiated in the manner described, gradually sets up structural changes in the kidneys, and that their inadequacy precipitates the mental outbreak—the brain perhaps being affected earlier than the kidneys. The subject, however, is so broad and far-reaching that the limit of this address will not permit more than this imperfect outline of it. In closing, I will not consume more time than to briefly point out remedial measures of a general character. Prophylaxis must ever be the leading indication. A study of individual and family idiosyncrasies in respect of foods is of great importance, because here we shall find the chief cause of those gastro-duodenal catarrhs that in after-life may result so disastrously. Dyspepsia in children with an inherited nervous or mental diathesis should, if possible, be prevented, but if not seen in time should be most systematically treated and cured, and recurrent attacks prevented by the strictest dietary. Especially would I urge the denial of starches and sugars, pastries, etc., to strumous and gouty children.

But what course of treatment shall we pursue in those threatened with mental disturbances from the causes here advanced? My plan is, first to regulate the diet and then to aid in the prompt elimination of offensive elements from the blood. To cases of melancholia I frequently give nightly a tablet composed of one-tenth of a grain each of calomel, podophyllin and ipecacuanha, followed in the morning by hot Carlsbad water, or hot Hunyadi Janos water; I may continue this tablet two, three or four weeks. At the same time, special treatment of the catarrhal condition will demand attention. So much has been written in recent years on the subject of gastro-intestinal antisepsis that I shall not occupy your time in going over the subject, except to state that in different cases bismuth, salol, charcoal, naphthol, carbolic acid, etc., have been employed with advantage; and, as advised by Dujardin-Beaumetz, I generally administer these in cachets. Special effort is made to avoid the ingestion of any food or drink likely to lead to undue fermentation or putrefaction. As regards solid foods, when there is a question between the use of the two, I much prefer medium-cooked meats to starchy or saccharine substances. The study of the urine will give us important signs as to the elimination of some kinds of waste, and the necessity for the restriction of such foods as supply this waste in undue proportions.

During my asylum experience I have often averted the impending outbreak of an otherwise mild chronic case by a brisk mercurial, followed by a few doses of compound jalap powder.

[3] Transactions of the State Medical Society of Pennsylvania, vol. xxi. 1889-90, p. 127.

In the London *Lancet*,[1] in 1889, a very suggestive case was reported by Dr. E. F. Willoughby, in which acute maniacal symptoms, occurring in a man about fifty years of age, were promptly controlled, and his reason restored within twelve hours, by copious diaphoresis from a hypodermatic injection of pilocarpine. Chloral and bromide had failed to procure sleep, which at once followed the use of pilocarpine. Cases like this indicate that diaphoretic elimination may be a potent factor in the treatment of some acutely maniacal patients.

I have had no experience in the matter of gastric lavage or irrigating the stomach by weak antiseptic solutions as a means of controlling putrefaction in that viscus, but would not hesitate to resort to it in appropriate cases. Dr. Frank Woodbury, in his interesting paper on "Infectious Dyspepsia and its Rational Treatment by the Antiseptic Method,"[2] refers to one case of incipient insanity in his practice apparently arrested by this agency.

In cases of mental disorder arising from renal disease, and deficient excretion by this channel, a milk diet, diuretics and diaphoretics will often give the most gratifying results. An elderly woman, now under treatment, whose mind became deranged from this cause, recovered her reason very promptly after taking an ounce and a half of compound jalap powder in doses of thirty grains every two hours. This did not produce catharsis, but proved abundantly diuretic and slightly diaphoretic.

VENESECTION IN CARDIAC AND ARTERIAL DISEASE.

BY H. A. LAFLEUR, M.D.,
FIRST ASSISTANT, MEDICAL CLINIC JOHNS HOPKINS HOSPITAL, BALTIMORE.

OWING to the discredit into which the practice of venesection has fallen during the last thirty years, one, at the present day, is almost expected to offer an apology for bringing the subject before a medical society. Such an apology exists in the fact that quite recently an interest in the subject has been revived, and at meetings of various medical societies and in current medical literature venesection has been discussed. Special reference may be made to a paper by Dr. Pye-Smith,[3] on "The Therapeutical Value of Venesection; Its Indications and Its Limits," read and discussed at a meeting of the Royal Medical and Chirurgical Society of London.

In this paper are recorded nearly fifty cases in which venesection had been practised in many different forms of disease, including bronchitis, broncho-pneumonia, croupous pneumonia, miliary tuberculosis of the lungs, thoracic aneurism, valvular disease of the heart, pericarditis, Bright's disease, apoplexy and epilepsy. The writer considered the indications for venesection in the order of their importance to be: First, cyanosis, with dilatation of the right side of the heart, whether from pulmonary or from some other form of obstruction to the circulation; secondly, the intense pain of thoracic aneurism; thirdly, uræmic and prolonged epileptic convulsions. Reference was also made to bleeding in fevers and inflammatory disorders. In the discussion that followed, the opinions expressed were in the main corroborative of the conclusions reached by the writer of the paper.

Since the opening of the Johns Hopkins Hospital, in May, 1889, we have had occasion to practise venesection on five patients, an account of which is subjoined.

CASE I. *Thoracic aneurism; venesection for urgent dyspnœa with cyanosis; temporary relief followed by death from exhaustion.*—William W., seventy-three years old, was admitted to the Johns Hopkins Hospital on May 18, 1889. He had been ailing for some months with cough, shortness of breath and pain in the right side of the chest and right shoulder; on admission he was found to present the signs of aneurism of the ascending arch of the aorta. He complained especially of shortness of breath and of intense pain over the right breast and down the right arm. With rest in bed and the use of iodide of potassium he improved slightly and the intense pain was somewhat alleviated, but at night he still suffered very much from dyspnœa and cough, for which morphia had to be used freely. On the evening of May 29th he had a more than usually severe attack of shortness of breath, accompanied by marked cyanosis and distention of the cervical veins. As his heart was beating strongly and regularly, it was considered that venesection would give him at least temporary relief, and, accordingly, fourteen ounces of blood were withdrawn from his right arm. This afforded him temporary relief: both the cyanosis and the dyspnœa became less, and he spent a more comfortable night. Shortly after the bleeding he had a profuse perspiration. He died from exhaustion two days later. The autopsy revealed a large saccular aneurism compressing the right lung, which was the seat of a chronic interstitial pneumonia.

CASE II. *Chronic nephritis, with dilated heart; extreme cyanosis; venesection, with temporary relief; death.*—Jeremiah B., forty-one years old, was admitted to the Johns Hopkins Hospital February 5, 1890. His illness had commenced six months before with shortness of breath, and three months later he had noticed that his legs were swollen. During November he had improved slightly, but since that time both the dropsy and the shortness of breath had gradually increased until the œdema involved his abdomen and arms. He had not noticed any change in the quantity or appearance of his urine. The condition of the patient on admission was as follows: Very plethoric and stout; general anasarca; respira-

[1] The London Lancet, No. 21 of vol. i., 1889, p. 1030.
[2] Journal of the Amer. Med. Assoc., vol. xv. p. 598.
[3] Abstracted in the Brit. Med. Journ., January 31, 1891.

tion a little labored, 44; pulse, 108, regular; no increase in tension. There was slight lividity of the lips and tips of the fingers and of the ears. The venules of the cheeks and nose were distended. There was a diminution of the area of lung resonance in the lower thorax in front, in the axillæ behind, and the breath-sounds at both bases were enfeebled. The cardiac dulness began at the third rib, but the inferior and lateral limits could not be made out. There was gallop-rhythm at the apex, a moderately intense systolic murmur in the anterior portion of the axilla, with accentuation and reduplication of the second sound at the pulmonary cartilage. The abdomen was very large, but there was so much fat that it was not possible to demonstrate any ascites. The urine was diminished in quantity, of a sp. gr. of 1028, and contained albumin and fatty, hyaline and granular casts. The patient was freely purged with salts and given half an ounce of the infusion of digitalis every four hours. During the next three days the urine progressively increased in qauntity, the dropsy was slightly diminished, and the heart-sounds became more distinct, though the pulse remained rapid. At midday, January 10th, after coughing up some bloody sputum during the morning, he had a sévere attack of dyspnœa, and when seen a few minutes later he was extremely cyanotic, the veins of the neck well distended, the breathing feeble and shallow, while the pulse could not be counted at the wrist. The heart-sounds were rapid and indistinct, and there was tremor and jactitation of the extremities. Venesection was deferred until 2.15 P.M., when eighteen ounces of blood were withdrawn. The relief was immediate, the breathing becoming easier and the cyanosis disappearing almost entirely. There was no return of the cyanosis or dyspnœa, but the patient died on the morning of the next day. An autopsy could not be obtained. It is probable that there were extensive hemorrhagic infarctions of the lungs.

CASE III. *Mitral regurgitation, with a dilated heart, irregular in action; cyanosis and dyspnœa; venesection, with marked relief; sudden death from syncope, six days later.*—Mark W., twenty-two years old, was admitted to the Johns Hopkins Hospital June 17, 1890. He had had three attacks of inflammatory rheumatism, the first occurring four years before, but had not shown any symptoms of cardiac mischief until three months previously to admission, when he began to be short of breath and to have palpitation on slight exertion. He had also suffered from vertigo and slight cough; his legs had been swollen for some days, and he was passing less urine than usual. Condition on admission: Face pale; slight blueness of finger-nails; œdema of the legs. There was orthopnœa. Respirations, 27. The pulse was intermittent, 36 per minute, only two out of a series of three beats of the heart reaching the radial pulse. There was slight impairment of resonance at the base of the right lung, with enfeebled breath-sounds. The whole of the left side of the chest was lifted with the cardiac systole, and there was throbbing in the neck and at the epigastrium. The apex impulse was forcible and diffused in the sixth intercostal space outside the nipple line. The area of cardiac dulness was increased in both diameters. There was irregularity in the rhythm and intensity of the cardiac beats, a loud whiffing systolic murmur at the apex, and marked accentuation of the second sound at the pulmonary orifice. The patient was ordered sulphate of strychnia, gr. $\frac{1}{60}$ t. i. d.; ten days later sparteine, gr. $\frac{1}{8}$, was substituted for this. There was some improvement in the pulse and the œdema partially disappeared.

On July 4th there were considerable cyanosis of the hands and lips, free perspiration, but not much dyspnœa. The pulse was very small and in marked contrast to the heaving impulse in the præcordial region. The heart's action was very irregular. Fifteen ounces of blood were withdrawn from the left arm. On the following morning the color of the patient was much better, the pulse was 96, of fairly good volume, the heart's action only slightly irregular, and there was no longer such disproportion between the cardiac systole and the pulse. The improvement continued until six days later, when the patient died suddenly in a syncopal attack. An autopsy could not be obtained.

CASE IV. *Arterial sclerosis; cardiac hypertrophy and dilatation; venous engorgement, with slight cyanosis, stupor and delirium; venesection; recovery.*—David B., fifty years old, was admitted to the Johns Hopkins Hospital December 16, 1890, suffering from cough, shortness of breath and dropsy, dating from fourteen weeks before entering the hospital. At that time he had been suddenly seized at night with shortness of breath and cough, and latterly the dyspnœa had been constant, with progressively increasing dropsy, with decrease in the quantity of urine passed daily. There had also been slight transitory mental disturbance. There was no history of rheumatism or syphilis. On admission he presented the following condition: Œdema of the lower extremities and of the right side of the trunk (he had been lying for some time on the right side); pulse, 116; vascular tension increased; respirations 44, breathing of the Cheyne Stokes type. There were bronchial râles at the bases of both lungs, but no dulness. The apex-beat was neither visible nor palpable, and the superficial area of cardiac dulness was not increased. There was fœtal heart-rhythm at the apex and gallop-rhythm at the fourth rib. There was no accentuation of the aortic second sound. The urine contained a small percentage of albumin, with a few hyaline and granular casts. With the use of digitalis, free purgation with salts and an occasional hot bath, the œdema rapidly subsided and the pulse became slower and of better volume. He still suffered from dyspnœa, however, and at night was very restless and slightly delirious. On December 23d he was not so well. His tongue was dry, his pulse more rapid and occasionally intermittent, and even in the daytime there were drowsiness and rambling. There was in addition considerable venous engorgement of all the superficial veins, with slight cyanosis and extension of the cardiac dulness to the right of the sternum. At 3 P.M. sixteen ounces of blood were taken from his left arm; the venous engorgement was lessened in a marked degree; the patient was restless until 3

o'clock in the morning, when he fell asleep. On the next day he was quite rational; there was still some dyspnœa, but his pulse was 96 and regular. During the three days following the bleeding he passed a very large quantity of urine. On January 7th he was quite free from dropsy, his mind was clear, he slept and ate well, and his pulse was regular, ranging from 60 to 70. He was discharged on this day at his own request. Three months later he called at the hospital and stated that he felt quite well and was at work.

Case V. *Mitral regurgitation, with dilated and irregular heart; extreme cyanosis; venesection; recovery.*—John B., forty-four years old, was admitted to the Johns Hopkins Hospital April 13, 1891, suffering from dropsy and shortness of breath. In the autumn of 1889 he had for three months suffered severely from inflammatory rheumatism, all his larger joints having been swollen and very painful, and in the same season of 1890 he had had an attack of typhoid fever. He gave no history of venereal disease. Four weeks before his admission to the hospital he had noticed that his feet were swollen. The dropsy increased rapidly; two weeks later he was quite short of breath—so much so that if he attempted to lie in bed he would choke. He had not complained of palpitation, his bowels were regular, and he passed about the same quantity of urine as usual. When seen, shortly after his admission to the ward, he was found to be cyanotic, sitting up in bed, and somewhat breathless. His pulse was from 90 to 100, small and irregularly intermittent. There was a wide area of heaving cardiac impulse, the apex beat being three fingers' breadth outside the left nipple. A loud, blowing, systolic murmur was heard at the apex, and was transmitted into the left axilla. The second sound was accentuated at the left border of the sternum. The lungs were clear, with the exception of a few mucous râles at the bases. There were enlargement of the liver, without ascites, and considerable œdema of the lower extremities. The urine was scanty, highly colored and albuminous; it contained some hyaline and finely granular casts. A milk diet, free purgation with salts, and tr. digitalis, ♏ xv. 4 q. h., was ordered. At midnight he was very cyanotic and breathing heavily. The radial pulse was just perceptible, only one heartbeat in every four or five being felt at the wrist. The præcordial impulse was heaving and irregular, and the heart sounds were loud. A bleeding of eighteen ounces produced immediate relief. The dyspnœa disappeared almost entirely, the cyanosis diminished, the pulse at the wrist increased in volume and frequency, and the patient was relatively comfortable for the remainder of the night. The next morning he was looking well, and sitting up in bed. There were still a little shortness of breath and blueness of the lips and finger-tips. The pulse was 96, of fairly good volume, but still irregularly intermittent. The upper limit of the cardiac dulness was at the third rib; transversely it extended from the right border of the sternum to the apex-impulse in the sixth intercostal space. There was some engorgement of the veins at the root of the neck. The auscultatory phenomena on the part of the heart and lungs were as described, and there was a slight elevation of temperature. The digitalis was discontinued, and was again given on the following day in smaller doses; two days later strychnine and strophanthus were substituted for it. From April 15th to May 1st there was irregularity in the volume of the individual beats, but no intermittency, and the urine was free from albumin and casts. On May 6th, after having been up and about for a week, he was feeling quite well. There was no œdema, lividity or shortness of breath, and he ate and slept well. The radial pulse was 80, small, irregular and once more occasionally intermitting. There was still a marked contrast between the force of the ventricular contraction and the volume of the pulse. The physical signs were not materially different from those observed the day after the bleeding. He was discharged from the hospital on May 6th.

The reported cases illustrate the value of bleeding, as a means both of affording temporary relief from distressing symptoms due to disturbances of the circulation and also of saving life and even restoring patients to comparative health. There is little to be added to Dr. Pye-Smith's conclusions as to the indications for venesection and its relative value in the various classes of cases which require its performance. Our experience has been, with one exception, limited to cases of primary cardiac or arterial disease, which are undoubtedly those in which most good may be expected from its use. Huchard[1] advocates small bleedings from time to time in the first stages of arterial sclerosis, and thinks that in this way it may be possible to lessen and even delay the evils resulting from prolonged high vascular tension. He insists particularly on the value of venesection in the later stages of the same disease, when the left ventricle is no longer able to cope with the increased peripheral resistance and volume of blood and the heart is in danger of sudden arrest. This may occur even when there is but little œdema or cyanosis, though there is usually engorgement of the right side of the heart and of the veins. In addition to its purely mechanical effect, venesection removes from the blood a considerable amount of toxic material which has accumulated in it owing to the imperfect performance of the functions of the kidneys and liver, these viscera being usually more or less affected by the general arterial sclerosis. The contra-indications to venesection in cardiac and arterial disease are few. Even when death is imminent the rapid abstraction of some ounces of blood not infrequently saves the patient. It is obvious that when marked ascites or pleural effusion coexists with cyanosis and distressed breathing the abdomen or the pleura should be tapped, and venesection delayed until it is ap-

[1] Huchard: Maladies du cœur et des vaisseaux. Paris, 1889.

parent whether either of these procedures will or will not afford relief. Large hemorrhagic infarctions of the lungs and extensive disease of the myocardium or of the coronary arteries, could such conditions be definitely ascertained, would probably be contra-indications, as even temporary relief could hardly be expected under such conditions.

CEREBRAL SURGERY.

BY FRANK P. NORBURY, M.D.,
ASSISTANT PHYSICIAN, ILLINOIS CENTRAL HOSPITAL FOR THE INSANE, JACKSONVILLE, ILL.

IN this day of surgical progress, operations of unheard-of magnitude are undertaken in regions of the body not long ago supposed to lie without the operative field. Especially is this true of diseases of the nervous system, which have heretofore been regarded as not amenable to treatment, but which are now removed or relieved by the surgeon's knife. The experimental researches and clinical observations of Ferrier, Horsley, Fritsch and Hitzig and others, have established the essential principles of cerebral localization, which, together with modern antiseptic and aseptic methods, have made it possible for the surgeon to invade diseased or injured brains. Brain surgery, although in its infancy, has been very progressive, until now the inaccessible areas of the brain have been narrowed down to the central regions of the base and the bordering convolutions, the corpora quadrigemina and the pons oblongata. (Charles K. Mills, *Brain*, July 18, 1889.)

The neurologist has been foremost in the diagnostic study of intra-cranial disease, but the fearless surgeon, with his technical skill, shares with the neurologist the rewards which have followed the united efforts of both in placing scientific cerebral surgery upon a firm and practical basis. My aim in this paper is to give a general review of what has been done in cerebral surgery. It is understood that the reader is cognizant of the principal facts pertaining to the surgical anatomy of the skull and brain, and it only necessary to add an outline of the established facts in cerebral localization.

The anatomy of the brain is still very defective, and the application of localization is exposed to much error; but from the results obtained by experimentation, clinical experience and pathological data, we are justified in drawing the following conclusions respecting the cells of the cerebral cortex: (1) The surface of the brain is the seat of all conscious mental action. Here, and here only, do impressions made upon the special senses become transformed into conscious appreciation of external objects. (2) The mental powers are represented by different combinations of memories of past events, stored in cells related to the special senses, and by the activity of other groups of cells that are probably situated in the frontal lobes. (3) The central convolutions of the brain (a part of the frontal and parietal lobes of each hemisphere) preside over motion and the memory of all motor acts of the limbs and body. The upper part governs the legs chiefly, the middle controls the upper extremity, while the lower presides over the complex movements of the tongue and lips necesaary to speech. The theory of centres exactly limited is probably not correct, for we have evidences of substitution of function when one centre is destroyed and its work is taken up by another. (4) The occipital lobes preside over the sense of sight and the memory of sight-pictures. Hallucinations of vision point strongly to a disturbance of function of the cells of these parts. (5) Parts of the parietal lobes not occupied by special centres of motion are probably associated with conscious perception of tactile impressions. (6) The temporal lobes are the probable seat of conscious appreciation of sounds, odors and taste. When these lobes are diseased, the memory of spoken words may be obliterated and hallucinations of hearing or deafness may be developed.[1] (7) The functions of other nerve-cells of the cortex are more or less open to controversy, while the functions of the cerebellum, pons Varolii and medulla oblongata are too complex to be fully discussed here. The region which concerns us most in the application of the principles of cerebral localization is the Rolandic zone or motor area. Diseases of the brain, situated in this locality, are more readily diagnosticated and are more amenable to treatment than when seated in any other region. The symptoms of localized cortical disease are divided into two classes, those caused by destruction and those caused by irritation. Destructive lesions produce paralysis, inhibit or obliterate sensation and impair the special senses. Irritative lesions produce spasm, tremor, contractions, hyperæsthesia, anæsthesia, pain and hallucinations of the senses. There are symptoms of a diffuse nature common to both forms of lesions, viz.: Headache, vertigo, vomiting, psychical changes, choked disc, coma.

In diagnosticating intra-cranial disease we must study each symptom separately and in association with others. In cerebral disease especially is diagnosis by exclusion unsatisfactory for surgical purposes. Familiarity with the cranio-cerebral relations is important. It is to-day an undisputed fact that every part of the cranial surface corresponds to a definite part of the cerebral surface. Therefore, to determine the location of our principal landmarks, so that we can undertake to map

[1] Ranney: Nervous Diseases, 1889.

out smaller areas, we must study the topographical relations of the cranium to the convolutions. Several methods have been suggested for establishing rules to guide us in localizing the fissures and convolutions. Hare's method seems the most practical and accurate. Dana (*Medical Record*, January 12, 1889; *Journal of Nervous and Mental Diseases*, June, 1890) has very explicitly given working rules for practical cranio-cerebral topography. By the aid of the cyrtometer we locate the principal landmarks, and from these we determine the other localities and areas. We can now understand the relations of surgery of the brain to the practical principles of localization and topography. Their application serves in the diagnosis and treatment of the various diseases of the brain coming within the domain of surgery, of which we may mention abscess, compression, tumor, cyst, fractures, hemorrhage, epilepsy, microcephalus, hydrocephalus, insanity and general paralysis.

The indications for surgical interference in cerebral disease are divided into two classes: (1) the existence of pressure symptoms, as in abscess, tumor, effusion, hemorrhage, etc.; (2) the existence of functional disturbances, such as epilepsy, inveterate headache, insanity, etc. (Keen). As a preliminary to all operations on the central nervous system, preparations should be made for several days previous to the operation in order to avoid shock, which is especially great in diseases of the nervous system (Dercum). Cerebral surgery is apparently the most difficult of all forms, and to succeed one must have a thorough knowledge of the technique. To the surgeon properly belongs the discussion of such procedures, but as any one of us may at any time be called upon to use the trephine, some consideration of this all-important operation in cerebral surgery—trephining—should be made here. "We are now," says Roswell Park,[1] "in a position in which we can boldly affirm, even in courts of law, that trephining, when properly done, is not of itself a dangerous operation. The condition which necessitates the operation constitutes the main element of danger. It is indicated in simple fracture with compression, compound fracture with depression, fracture associated with punctured or gunshot wounds, even in the absence of symptoms; coma, with signs of compression or contusion; laceration of soft parts, without fracture of the external table; hemorrhage, abscess, tumor, bone-abscess in the frontal sinus or mastoid process, purulent meningitis, acute infectious osteo-myelitis of the diploë, epilepsy, etc."

The Operation.—First of all, aseptic conditions must be established; the patient's scalp must be carefully shaved and cleansed. If no open wound exists, an incision, preferably U-shaped, should be made, so that perfect drainage will be assured when the patient lies on his back. The pericranium is then elevated or scraped back over the area of bone to be removed. The trephine should not be applied over vascular areas. The opening may subsequently be enlarged in any direction.[1] When it is intended to replace the button removed, it should be placed between folds of antiseptic gauze, and kept in a 2 per cent. solution of carbolic acid at a temperature of from 100° F. to 104° F. Before replacement a little notch should be cut for drainage, the pericranium sutured, and the scalp closed in the usual manner. Several methods have been proposed for filling openings made in trephining: re-implantation of the button, as suggested by Macewen; transplantation of bone from other parts of the patient (Seydel), and transplantation of bone from one animal to another. In either method, if the operation has been aseptic throughout (and in this branch of surgery it should be so more than in any other) perfect bony union will have taken place in a few days.

Trephining, when indicated, should be done early. In fracture of the skull, surgical interference is only justifiable when some well-pronounced or grave cerebral disturbance results. Then we may trephine and elevate the bone at the seat of pressure, or where the inner table, from its brittleness, may have become separated, with or without external fracture and injury to the brain.

In contusion of the brain we have, with the possible exception of cranial fracture, the most frequent cause of death as a result of injuries of the head as a class. In a paper read before the New York Medical Association last year Dr. Phelps thus summarizes his conclusions regarding cerebral contusion: "It may be either direct or by *contre coup*, and may be either limited or diffuse or attended by hemorrhage upon the surface of the brain. This last form may cause death by compression. The limited or diffuse form may cause early death by consecutive general hyperæmia, or later by the formation of cerebral abscess. The symptoms resemble alcoholic intoxication, for which the condition is usually mistaken.

Keen advises trephining when encephalitis follows contusion. He says: "We should treat such an inflammation precisely as we would treat it in other regions of the body, always remembering that in the brain, by reason of the bony case in which it is retained, it is impossible for an exudation or hemorrhage to find its way to the surface without surgical assistance." We should treat fractures of the vault without depression expectantly, but when encephalitis occurs the trephine should be used. Keen advises immediate preventive trephining when

[1] Roswell Park: Ref. Hand-book.

[1] Roswell Park: Med. Record, September 22, 1888.

depression exists; the harmlessness of trephining by modern methods is so assured that no patient should be exposed to the risks of immediate or remote consequences. In fractures of the base Nancrede[1] says: "In addition to elevation, disinfection and removal of fragments, we should fill by insufflation and packing all accessible localities." Fractures of the vault in children are of grave consequence. Simple fracture, involving the membranes and brain, may be attended by one of two possible complications, viz., a cranial gap, with the brain in direct apposition with the bone, pulsating at the bottom of the opening, or a false meningocele; the watery tumor may communicate with the interior of the skull, or the opening may close by bony or fibrous union. Meningocele may complicate simple or compound fracture or follow trephining or other operation on the brain. The presence of meningocele is proof positive that the lateral ventricles have been involved.[2]

Pressure exerted by cranial tumors is indicated by headache, vertigo, vomiting, epileptiform convulsions, apoplectiform attacks, psychic disturbances and choked disc. Headache is generally localized and usually frontal. It is often related to the seat of the tumor. In several cases coming under my observation I have seen persistent headache, with nocturnal exacerbations.

Vertigo is not always present. It is most frequent when the cerebellum is involved. Vomiting may be a pronounced symptom, but it occurs principally in cerebellar disease. The cerebellar gait, the vertigo, the vomiting and subsequent coma, with associated paretic symptoms, led me in one case to diagnosticate tumor. Death occurred, and post-mortem examination showed cerebellar abscess. Epileptiform and apoplectiform seizures are quite frequent, and are characteristic symptoms of tumor. Transitory hemiplegia may follow the apoplectiform attacks, especially when in association with gummatous tumors of brain. The psychic changes are principally of the maniacal or melancholic forms of insanity. Choked disc, when present, is more nearly a pathognomonic symptom of cerebral tumor than any other (Jacobi). Tuberculous tumors are not suitable for operation. Gliomata, when not vascular and rapidly growing, admit of ready removal. Cysts are favorable for operation. Fibromata of the membranes are most amenable to treatment. Sarcomata and carcinomata are not. Gliomata are usually seated in inaccessible regions of the gray matter and are apt to give rise[3] to apoplectiform attacks. Cerebellar tumors are not favorable for operation.

Cerebral abscess occurs chiefly in the temporo-sphenoidal lobe, or in the cerebellum, or in both together, as I have observed. The abscesses may be single or multiple, and acute or chronic. They are caused principally by extension of disease from the middle ear, or by traumatism; they may be secondary to erysipelas of the face or scalp or to the eruptive fevers. The symptoms are vertigo, anorexia, chills, elevated temperature, accelerated pulse, etc., cephalalgia, insomnia, disturbance of equilibrium; percussion may elicit sensitiveness over the region of the abscess. It is difficult to diagnosticate abscess, as I know from experience; the only certain method is by the use of an exploring needle in the region of its supposed existence. As a rule, the pressure symptoms will enable us to localize it. The treatment is to evacuate the abscess by trephining above and behind the ear, according to rules laid down by Bergmann. Macewen makes a second opening on a line with the bottom of the abscess. Nancrede[1] indorses this treatment, saying that it is necessary to facilitate drainage in washing out the abscess. A weak bichloride solution should be used.

The operation of linear craniotomy for microcephalus has been performed in this country, first by Keen,[2] later by Wyeth.[3] Lannelongue, of Paris, was the first to operate for the relief of this disease. His first case was greatly improved, but the intellectual acquirement was in a great measure due to the training received in the hospital. Wyeth's case improved quite markedly. I have not learned the results in Keen's case. All cases of microcephalus are not amenable to such treatment, for microcephalic brains show the effects of two entirely different conditions—premature closure of the sutures, which checks the active growth of the contained brain, and cessation of the growth of the skull because the brain from some cause has ceased to grow, the skull no longer receiving the stimulus of the growing organ within.[4] In the first class of cases an operation would no doubt relieve the conditions producing imbecility and allow the enfeebled brain to attain a larger and more natural growth; but the second class of cases would not be benefited in the least. My experience as assistant physician in the Pennsylvania Institution for Feeble-minded Children has led me to believe that whatever benefit cases of microcephalus would derive from such a surgical operation would be due to methodical and persistent training such as is pursued with all feeble-minded children. Such a child would, at best, in intellectual acquirement never approach a normal child of the same age.

Hydrocephalus has been operated upon with more or less success. There are two varieties—external (when the effusion is in the sub-arachnoid space), and internal (when the effusion is in the ventricles). Conner[1] advises in external hydrocephalus that only a moderate amount of fluid be drawn off at a time with an aspirator. For internal hydrocephalus Keen has devised an operation for draining the ventricles, which is briefly as follows: Lateral trephining, large opening one and one-quarter inches behind the auditory meatus and one and one-quarter inches above Reid's base line; puncture at a point two and one-half inches directly above the opposite meatus.[2] The puncture opens into normal lateral ventricles. The objection to this operation, says Conner, is the reaccumulation of fluid which invariably follows. Of the seven cases reported up to September, 1890, five had died, showing a high rate of mortality; but Keen does not regard this as discouraging, considering the danger of the primary condition. An interesting case is reported by Ayres,[3] in which paracentesis was done for internal hydrocephalus. The child was a blind imbecile. Great improvement followed the operation. The eyesight was restored, the mental condition improved, but the child could not talk. The subject of tapping the ventricles was last year discussed before the British Medical Association. Mayo Clark regarded the operation as justifiable in cases in which coma developed. Wheelhouse, of Leeds, said that the operation should not be done in chronic hydrocephalus. When the operation is performed it should be done with strict antiseptic precautions.

Gunshot wounds of the skull and brain have interested surgeons since the invention of gunpowder. In this day of perfected firearms they are troublesome, severe and dangerous. Professor Bryant, of New York, states that the mortality depends greatly on the removal or non-removal of the foreign body; recoveries are greater by 17 per cent. when foreign bodies are removed. This applies especially to the frontal, parietal and temporo-sphenoidal lobes. When a bullet lies above the plane of the lateral sinus the chances of recovery are fair; but when below, death is inevitable. When the cerebellum is injured, death is the usual result, irrespective of treatment. It is often very difficult to locate the bullet in the brain. Numerous instruments have been devised; none, perhaps, is more simple or more satisfactory in action than the telephonic probe devised by Dr. John Girdner, of New York. It is not universally used because the Bell Telephone Company will not permit its manufacture. The improvised instrument is used as follows: One copper wire is attached to a probe, the other to a piece of metal held in the patient's hand, and an ordinary Bell telephone receiver is placed to the ear. The metal plate should be of the same material as the probe. When the probe comes in contact with the bullet a signal is given. The signal was given in all of eight cases examined with this instrument.

Hemorrhage, either arterial or venous, arising in the course of intra-cranial operations is often troublesome. In the surgery of the skull it mostly takes place in two situations, viz.: externally or internally to the broad aponeurosis of the scalp and in the sub-aponeurotic fossæ; in the latter bloody effusions, hæmatomata, are most frequently met.[1] Bleeding from the diploë may be troublesome, but it can be controlled by pressure or by plugs. Intra-cranial hemorrhage may prove serious from its location and duration. It may be supradural, subdural, cortical and intra-cerebral. Supradural and subdural hemorrhage is usually associated with fracture. Cortical or subcortical hemorrhage has its source in the cerebral arteries and most frequently in the cortical system of the middle cerebral.[2] Cortical hemorrhage is rare, meningeal hemorrhage frequent. Intra-cranial hemorrhage is becoming more and more subject to treatment at the surgeon's hands. When subdural or epidural, the clot will not be absorbed, and surgical interference is justifiable (Dennis). Manley is convinced from experience that in cases of cranial lesions attended with intra-cranial hemorrhage, trephining and displacement of the clot are illogical and constitute dangerous practice[3] unless there are well-defined indications. Osler says that intra-cranial hemorrhage, not traumatic, is beyond the province of surgery; while Chambonier[4] gives reports of thirty-one cases of non-traumatic hemorrhage operated upon by him without a death. He also states that hemiplegia and muscular contractions have been relieved by the removal of old clots. The symptomatology of hemorrhage is briefly as follows: Motor and sensory paralysis, varying in extent, duration and degree; disturbance of consciousness and of the special senses; abnormal attitude of the head and eyes; tremor; changes in the pulse, pupils, temperature and respiration; abnormal phenomena of the bladder, rectum and kidney; and mental impairment.

Starr says that no definite statements regarding the advisability of surgical interference in Jacksonian epilepsy can be made. We may relieve, but in no case can we promise cure.[5] To afford relief

in epilepsy, trephining has been done since prehistoric times, but it is as yet by no means established in what degree it has proved successful as a curative measure. The actual number of cases of traumatic epilepsy is not as great as statistics would lead us to believe. Fits may cease for a longer or shorter period after trephining, just as they do after almost any surgical operation, to return with usual or increased severity. Ferrier[1] says that at least one year should elapse without recurrence of fits before it would be safe to pronounce a case cured. In conducting the operation it is often impossible to recognize the sulci and convolutions and to locate the discharging lesion. In such case resort may be had to the faradic current, which, when weak, does no harm to the cortex. Keen has devised for the purpose an electrode which is as unique as it is serviceable. Hughlings-Jackson advises that in all cases of focal epilepsy, depending on organic disease or not, the discharging lesion should be excised. In all cases excision should be as complete as possible, and all irritable portions of the brain cortex be removed to prevent the recurrence of spasms. Spasms occurring after such a precaution has been taken are a result of the epileptic habit or of irritability and instability of neighboring centres.[2] When brain pressure exists after trephining, the button of bone is left out. Marked amelioration has followed such procedure.

Operations for the relief of insanity and general paralysis have been undertaken, but with no great success. In general paralysis three operations have been reported—two in England by Drs. Shaw and Cripps,[3] and one in this country by Dr. Charles G. Wagner,[4] of Utica, N. Y. Temporary improvement followed in all, but death ultimately resulted at periods varying from a few weeks to a few months. Dr. Wagner admits that, while the utility of the operation is not fully established, yet he regards the improvement which followed in the cases operated upon as a warrant for further trial of trephining in general paralysis.

In summing up what can be done in cerebral surgery I will quote the conclusions of a report read before the International Medical Congress, 1890, by Victor Horsley, of London, one of the foremost surgeons and experimenters in this line of work:

1. Operation should be done in every case of brain injury. It is the only means of restoring the patient to a normal condition and may prevent epilepsy and dementia.

2. In every case of intra-cerebral hemorrhage, seen within four hours of the apoplectic attack, the common carotid artery should be tied.

3. Trephining should be done in cases of headache refractory to all other measures.

4. Cerebral gummata should be removed; iodide of potassium palliates but does not cure them.

5. Tubercles should be removed when practicable.

6. Operation should be performed when other tumors are present, even when multiple, if relief is not obtained from other measures in six weeks.

7. Operation should be performed for athetosis and other spasmodic affections.

8. Operation should be performed for Jacksonian epilepsy, after first testing the cortex with the faradic current to locate the point of origin of the convulsion.

9. Operation should be performed for fracture of the vertebral column when compression exists.

10. Operation should be done for paraplegia from spinal caries.

Horsley represents aggressive cerebral surgery. Perhaps he is an extremist, or possibly we have not yet awakened to the possibilities of operative surgery in diseases of the brain and spinal cord.

RENAL DISEASE AND URÆMIA ATTENDING ACUTE FACIAL ERYSIPELAS.

BY JULIUS L. SALINGER, M.D.,
ASSISTANT DEMONSTRATOR OF CLINICAL MEDICINE IN THE JEFFERSON MEDICAL COLLEGE.

THE following case demonstrates the relation of acute facial erysipelas to disease of the kidney, and shows the necessity of paying the most careful attention to the renal function in acute erysipelas:

Mrs. G., aged fifty-seven years, tall and of good physique, weighing 165 pounds. Thirty years ago had an attack of inflammatory rheumatism, followed by an aortic regurgitant murmur; she had been previously well, and had never had any other complaint except an occasional sick headache. For three days she had been suffering with sharp pains in the large joints, but without heat, swelling, or any rise of temperature. Her pulse was 70, of fair strength and volume, and the temperature was 99°. I ordered her 15 grains of sodium salicylate every four hours, and in three days she was able to leave her bed and be about, all pains and aches having disappeared. Her temperature had reached 100° at no time during her illness.

Two days after the patient had left her bed I was sent for. The patient complained of pain and a burning sensation of the alæ of the nose and of the right cheek. This, following a severe chill, had come on suddenly during the night On inspection there was a scarlet-red rash, slightly raised, with a well-defined border. The parts about the eruption were hot and œdematous. The pulse was 120, and feeble, the temperature being 102½°, which in the evening of the same day rose to 104⅕°. Upon the most careful examination I was unable to discover the slightest history of traumatism. I recognized

the disease as facial erysipelas, and adopted a plan of treatment introduced by Professor J. M. Da Costa—the administration of pilocarpine hypodermatically. In this instance, however, on account of the old valvular difficulty, I ordered pilocarpine, grain $\frac{1}{6}$, by the mouth, every four hours. The eruption was dusted with bismuth subnitrate.

The eruption spread rapidly, so that on the morning of the fourth day of the disease it involved the entire scalp and the face, with the exception of the chin. Both eyes were closed, and greatly swollen. The patient suffered great pain and smarting, complaining very much of occipital headache, insomnia and nervousness. There was complete anorexia. She complained of considerable pain in the lumbar region and in the loins. The temperature was very variable, ranging between $102\frac{1}{2}$–$105\frac{3}{5}°$, and at one time during the disease it reached $106\frac{1}{5}°$, the evening temperature being always higher than that of the morning. The pulse throughout was quick, feeble, occasionally intermitting, and ran from 120 to 150 per minute.

The urine was examined daily, the first three days being normal, and the urates becoming much more marked as the disease advanced. On the morning of the fourth day albumin appeared. There were no tube-casts. On the fifth day the existence of albumin became marked, and hyaline tube-casts were found. On the seventh day albumin was one-half by bulk in the test-tube. The patient was now passing four ounces of urine in twenty-four hours. She took very little nourishment, and was generally in a comatose condition, with low muttering delirium, from which she was raised only with the greatest difficulty. These symptoms increased during the night. Professor Da Costa now saw the case with me. On the eighth day the patient had four uræmic convulsions that began with twitchings of the muscles of the face, thence extending to all parts of the body. The convulsions were very violent. Following the convulsions there was the profoundest coma. The first of the uræmic seizures was by far the most severe, and lasted fully one hour. Some of the urine was drawn after the first convulsion; sp. gr. 1022, reaction acid, albumin one-half by bulk, no sugar; epithelial, granular and blood casts. The granular and epithelial casts were very numerous. The spleen was decidedly enlarged. Swelling of both feet now set in. The patient was put on the infusion of digitalis, ʒij every two hours.

On the eleventh day considerable improvement was noticed. She was now passing twelve ounces of urine, and the eruption began to fade. The temperature was $101\frac{1}{2}°$. She was still in a semi-comatose state, but could be easily roused, after which she would again relapse. The albumin was diminishing, but tube-casts were still present. From this time the improvement was rapid. The eruption faded more each day, the urine increased in quantity, and the albumin diminished. On the twentieth day the patient passed a little over one quart of urine, albumin and tube-casts being still present. All traces of eruption were gone and the patient was able to leave her bed, although she was still very weak. Her temperature was normal.

Two days afterward the patient complained of pain in the throat and difficulty on deglutition. On inspection the throat was found to be red and swollen. The tonsils were enormously enlarged. She complained of headache and pain in the ears. The temperature was $102\frac{1}{2}°$. The pulse was 100. The tonsillitis, for such the throat condition undoubtedly was, lasted six days. Pus formed in each tonsil, and after being evacuated the patient recovered, although a tender condition of the throat remained for some time afterward. All traces of the erysipelas were gone, the desquamation having been thorough. Considerable thickening of the skin had taken place. Albumin and epithelial casts still persisted in the urine, and are present to-day after a lapse of two and one-half years. The patient lost fourteen pounds during her illness.

The treatment consisted in giving pilocarpine gr. $\frac{1}{6}$ in pill every four hours. When the kidney symptoms became marked the pilocarpine was discontinued. Inf. digitalis ʒij every two hours was given, and dry cups were used over the kidney.

The tonsillitis was treated in the usual manner by guaiac, etc. In acute facial erysipelas I have seen pilocarpine hypodermatically do wonders. After setting up considerable sweating the eruption has disappeared in three days. But it can be given with safety only to the strong and robust.

My reasons for narrating this case at length are to call attention to some symptoms which are of great importance, and are usually overlooked. For instance, the kidney disorder is not mentioned in the majority of our text-books, and where it is mentioned but slight notice is taken of it, and it is quickly dismissed as a slight complication. Da Costa ("Internal Complications of Acute Erysipelas," *Amer. Journ. Med. Sci.*, Oct., 1877) was the first to call attention to the constancy of this symptom. It occurs in nearly every case of erysipelas, certainly in every well-marked case. It even occurs in traumatic erysipelas. It is not an early symptom. About the fifth or sixth day of the disease a trace of albumin will be found in the urine. This trace will remain for several days, and disappear as the case improves. If, however, the patient should get worse, and the disease spread, the albumin increases in quantity and tube-casts begin to make their appearance. I have observed this in five different cases. The amount of albumin in this way becomes a guide to prognosis. It always reappears in a relapse, although it is usually not so marked nor so constant as in the original attack.

The albumin may be explained in several ways. It may be due to the general derangement of the blood, such as we find in the low fevers and in some forms of rheumatism. But a more likely view is one that is borne out by the post-mortem appearances of the kidneys. After a death from erysipelas the kidneys are found engorged with blood, congested, and even in a state of parenchymatous inflammation—

in other words, a true acute or subacute nephritis. (Ponfick, *Deutsch. Klin.*, No. 20, 1868.) It would be very difficult to account for such a large amount of albumin and tube-casts except by the fact that a true inflammation of the kidney takes place, as in the case of scarlet fever, though generally of a much milder type. This calls to mind the analogy between inflammation of the skin and disease of the kidney. There is not a single true acute inflammation of the skin in which we do not find albumin in the urine. The intimate physiological connection between the skin and the kidney readily explains this. In scalds and burns we find albumin in the urine, just as in the same connection we find ulcers of the intestines (principally of the duodenum). To make the connection still closer we also have ulcers of the duodenum and of the other intestines in acute erysipelas. Larcher (*Arch. Gén.*, 1864) reports two cases; Malherbe (*Arch. Gén.*, 1865) reports one case.

The uræmic convulsions that occurred in this case can of course be explained by the condition of the kidney and the albumin circulating in the system. I have not been able to find another case of erysipelas in which uræmia occurred. It must be set down as a rare complication. Œdema of the legs occurs whenever the amount of albumin becomes excessive, and has frequently been observed. Friedreich (*Klin. Vorträge*, No. 75, 1874) states that swelling of the spleen is quite common in erysipelas. Heart murmurs occur, and throat complications are also often met with.

It seems, then, that in acute erysipelas the symptom of most importance after the eruption is the albuminuria. By observing whether the albumin is increasing or diminishing we know how our case is progressing, and that whenever the disease assumes a graver type it is necessary to pay most particular attention to the condition of the kidney.

ON THE RELIEF OF CHRONIC CATARRHAL DEAFNESS BY EXCISION OF THE MEMBRANA TYMPANI AND THE TWO LARGER OSSICULA.

BY CHARLES H. BURNETT, M.D.,
CLINICAL PROFESSOR OF OTOLOGY, WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA; AURAL SURGEON, PRESBYTERIAN HOSPITAL, ETC., PHILADELPHIA.

SINCE the treatment of chronic catarrh of the middle ear, with its attendant deafness, tinnitus aurium, and vertigo, forms about three-quarters of the aurist's work, and as the results are very often unsatisfactory, I am induced to publish the following case as illustrative of the benefits of a new treatment of this hitherto intractable aural malady. Let me premise this short account by the statement that I have been induced to perform the operation of excision of the membrana and the two larger ossicula in chronic catarrh of the middle ear, because I believe that what we have to contend with in these cases is ankylosis, in whole or in part, of the conductors of sound lying in the middle ear, incurable in any other way. The relief obtained in the case I am about to narrate can be explained in no other way than that the removal of the ankylosed membrana, malleus and incus permits the stapes to vibrate more freely in its oval window. If the stapes is also ankylosed, the relief of deafness is slight or is entirely wanting, though even in such a case the tinnitus and vertigo, as shown in a case already reported by me,[1] may be entirely and permanently relieved.

July 15, 1889, Mrs. X., twenty years of age, stated that eighteen months previously she had camped out in Syria. She found it very damp and cold at night and took a severe cold in her head. Since then she has had pulsating tinnitus and increasing hardness of hearing in her left ear, with fulness in the head and at times vertigo from the excessive tinnitus. Upon returning, her family observed that her voice sounded as if she had a cold in her head. During the past year she underwent treatment of the fauces at the hands of an oculist, who also inflated the ears by Politzer's method, but without benefit; in fact all the bad aural symptoms increased.

When first seen by the writer her condition was as follows: Left membrana tympani retracted and depressed, especially over the incus-stapes joint. Hearing in the left ear, four feet, for isolated words of ordinary conversational tone. There was a constant, pulsating tinnitus in the left ear, with some slight constant singing tinnitus in the right ear. The Eustachian tubes were pervious to inflations. The nares showed general, active, hypertrophic catarrh. The pharynx was in good condition.

Treatment.—Dobell's spray was used by patient once daily at home. In the course of a fortnight the nares looked better and the tinnitus in the right ear became much less. The tinnitus in the left ear, however, was no better. The catarrhal symptoms grew worse by September, 1889, and from this time until March, 1890, treatment consisted in the use of Dobell's spray by the patient at home, and in injections into the Eustachian tubes by means of the syringe-catheter, once or twice a week, by me. The hearing in the left ear, however, diminished to *six inches* for isolated words and the tinnitus was great and annoying. The hearing in the right ear remained very good and the tinnitus very slight.

By August, 1890, as the sprays to the nares and the injections into the Eustachian tubes did no good, and as the hypertrophies from vasomotor paresis remained undiminished and the nasal respiration was impeded, each lower turbinated mucous cushion was incised at three points, one behind the other, at six different times by means of the galvano-cautery. This permanently reduced the hypertrophies, restored the nasal respiration, the catarrhal

[1] The American Journal of the Medical Sciences, February, 1890.

symptoms in the naso-pharynx becoming better, but the ear-symptoms remained unimproved.

In March, 1891, the hearing in the left ear was only six inches for isolated words and the pulsating tinnitus very great, with sudden accessions, which induced great vertigo. It was therefore decided to perform excision of the membrana tympani and the two larger ossicula in the left ear.

On March 5, 1891, the patient was etherized, and under illumination of the ear by means of the electric head-lamp, an incision was made through the membrana tympani, comprising its upper posterior quadrant, and the incus exposed. I then passed a small oval blade, two mm. long, set at right angles to the shaft, behind the incus and severed the incus-stapes joint; I drew the incus a little downward with the blade of the knife, and seizing the incus with forceps lifted it from the tympanic cavity. Then I excised the rest of the membrana about the periphery and withdrew the malleus and the membrana from the auditory canal. I dressed the ear with a tampon of bichloride cotton placed about half-way down the canal. The next day there was no reaction, but the hearing was now *four feet* for isolated words. The tinnitus was not diminished. The ear had lost its stopped-up feeling and all sensation of pressure in it had gone.

On the third day after the operation, after exposure to cold wind, the ear began to bleed a little, and finally a glairy, transparent, mucus-like discharge set in, and continued for about six weeks, when the regeneration of the membrana tympani became complete. On April 29th the new imperforate membrana was plainly seen, somewhat congested. Hearing for isolated words was now *four feet.* The tinnitus was still considerable. On June 4th the new membrana was uncongested and bluish. Hearing for isolated words was *twelve feet.* Pulsating tinnitus and vertigo had ceased. There was some slight, constant tinnitus if the patient listened for it, but no sensation of fulness in her left ear. The patient says she can hear conversation of a companion sitting on the left side without turning around, as she had to do before the operation.

I would call attention first to the improved hearing (from six inches to four feet) immediately after the operation, and also to the disappearance of the sensation of pressure in the ear, so annoying before the operation. Doubtless, the latter sensation was due to the pressure from retraction of the membrana and ossicula.

Secondly, note the progressive improvement in hearing, notwithstanding regeneration of the membrana tympani. The stapes, being now unimpeded by the retraction of the membrana and ankylosed malleus and incus, vibrates under sonorous waves, notwithstanding the intervention of a new membrana.

Thirdly, and with emphasis, I would call attention to the entire relief from pulsating tinnitus and attacks of dizziness. The relief of the vertigo is due to the removal of the mechanical pressure exercised by the in-drawn malleus and incus upon the stapes. The latter consequently being freed from impaction in the oval window, no longer compromises the labyrinth-fluid and irritates the motor filaments of the auditory nerve. The tinnitus is diminished because the congestion in the middle ear, due to the irritation brought about by the above-named retraction and impaction in the oval window, is removed.

ORIGINAL LECTURES.

APPENDICITIS. CASTRATION FOR SARCOMA OF THE TESTIS. WIRING FOR COMMINUTED FRACTURE OF THE PATELLA.

Abstract of a Clinical Lecture delivered at the Roosevelt Hospital.

By CHARLES McBURNEY, M.D.,
ATTENDING SURGEON.

Two cases of appendicitis were shown. The first patient was a man, twenty-eight years old, who began to have slight pain in the right iliac fossa two weeks previously. Although suffering pain, he continued to go about until presenting himself at the hospital. There was a good deal of pain and tenderness in the right iliac region, with some irritability of the bladder. There had been no vomiting; the pulse was 90 and the temperature 99° F. The bowels had moved regularly up to thirty-six hours previously. At the first examination pressure made with a single finger, at a point about two inches to the inside of the spine of the ilium, elicited marked tenderness. This point of tenderness is of much diagnostic value in distinguishing between disease of the vermiform appendix and inflammatory disease of other parts. There was slight tenderness toward the pubes and unusual resistance to palpation over the right iliac fossa. In such cases the diagnosis is often most difficult; but accepting its correctness, the question of the time to operate becomes important and deserving of thoughtful deliberation. Early operation is to be recommended; because, although such intra-peritoneal collections of pus may long remain quiescent, very slight traumatism or inconsiderable interference with the general health might cause a rapid development of inflammation with abundant formation of pus, followed occasionally by perforation into the peritoneal cavity. There is no possible way of knowing beforehand what might happen in these cases. The operation is dangerous, and, owing to firm intestinal adhesions, oftentimes difficult; but the danger of the operation is considerably less than the risk of leaving the case alone.

An incision along the edge of the rectus muscle extending from two inches above the anterior spine of the ilium down to within one-quarter of an inch of the deep epigastric artery, would pass through the external oblique aponeurosis, and the abdominal wall would be incised along this line, as the hemorrhage here would be slight. The cavity could then be opened and search made for the diseased organ; if it were not readily found the base of the appendix could be sought at its point of origin from the cæcum. If the appendix can be isolated, it should be ligated within one-eighth of an inch of the

intestine and then excised. The stump, before being returned, should be disinfected by the application of the actual cautery. As this stump is very minute, the plan of covering it with peritoneum is not readily accomplished, and offers no advantage on the ground of safety.

In the present case, on passing the finger into the peritoneal cavity, the appendix, much distended and surrounded by pus, was found to pass inward and behind the head of the colon, the surrounding tissues being generally adherent. The appendix was isolated by gently breaking up the adhesions with the finger, was ligated and excised, and the stump cauterized. A drainage-tube was inserted, and several sutures were passed through the entire thickness of the abdominal wall, so as to coaptate a portion of the wound, the remainder being packed with iodoform gauze. The intestines pressed against the gauze packing, but within twelve hours adhesions would probably be formed, shutting off the general peritoneal cavity from the wound. The dressing, which consisted of sublimate-gauze and cotton, should not be touched until the third day, unless there be pain or a rise of temperature; then the packing should be removed and renewed. Little or no irrigation would be required. The result in this case justified the emphasis which had been laid upon the importance of early exploratory incision; for, although this patient had been able to go about most of the time and had had a temperature of only 99° F., an abscess was found behind the intestines which was liable to rupture at any time.

The second case, although also one of appendicitis, differed materially from the first. The patient, a boy seventeen years old, began to have pain in the right inguinal region ten days previously, but did not go to bed until three days later, and had no medical attendance for two days more. With the exception of continuous pain in the right iliac fossa he had been fairly comfortable. He has had no vomiting and no abdominal distention; his temperature has ranged between 101° and 102° F. Examination disclosed, close to the iliac spine and along the outer half of Poupart's ligament, over an area of about two and a half inches wide, the existence of considerable tenderness, with slight resistance and percussion dulness; but fluctuation could not be detected. The characteristic point of tenderness, as described in the preceding case, was also present in this. A diagnosis of intra-peritoneal abscess from appendicitis was made. Inflammatory adhesions had probably formed between the surrounding intestines, so that when perforation took place the extravasated fluid had been shut off from the general peritoneal cavity. Formerly such cases were allowed to open spontaneously by a very slow process, or else rupture into the peritoneal cavity, giving rise to fatal suppurative peritonitis. It remained for Dr. Willard Parker to show that when such abscesses had reached a certain size they could, like any other abscess, be opened with safety any time after the seventh or tenth day; but until quite recently it was erroneously considered that these abscesses were situated outside of the peritoneum, the abscess having formed next to the appendix or the head of the colon, then working its way through into the cellular tissue between the peritoneum and the iliacus muscle, and in this way up to the groin. This occurs rarely; almost all such cases were originally intra-peritoneal; but a sac was formed for the abscess by adhesions between the viscera covered with peritoneum and the anterior and posterior abdominal walls.

Since, in this case, the abscess was already formed, there was no propriety in making an incision into the general peritoneal cavity. The incision was made close to Poupart's ligament so as to enter the abscess directly. At this late stage there was no use in looking for the diseased appendix. For two reasons exploratory puncture previous to the operation is not to be commended; first, because the puncture often fails to find fluid when present, and secondly, because the operator who depends upon this test and fails to find pus would hesitate to operate. The first puncture might injure an important viscus, and if on withdrawing the needle through the peritoneum pus were reached, infection might take place. After having made an incision there is not so much objection to an exploratory puncture in order more definitely to locate the pus; but even then, the procedure is not necessary. Close to the peritoneum œdematous tissue, suggestive of the presence of pus, was encountered. The abscess was found and evacuated; on introducing the finger into its cavity two small concretions, which had given rise to the trouble, were found and removed. The walls of the abscess had been formed by adhesions in the manner described, and the agglutinated convolutions of intestines could be felt. After irrigating the abscess cavity with boro-salicylic solution, a drainage-tube was inserted and the cavity packed with iodoform-gauze. If in this instance the incision adopted in the preceding case had been employed, it would have been necessary to evacuate the abscess through the general peritoneal cavity, thus greatly increasing the danger.

The next case presented was that of a boy about eighteen years old, who had a tumor of the right testis. About one year before, the testis was injured, immediately swelling to one-half its present size. The mass, which was very tender, was extremely heavy, very dense, semi-elastic, and extended up beyond the external abdominal ring. The spermatic cord was somewhat enlarged. While there was a possibility of the case being one of hæmatocele, it was more probably one of sarcoma. An incision was made over the anterior surface of the tumor and the parts rapidly dissected away. After extending the incision up to the internal ring, it was found that the growth extended still further and involved the peritoneum where it was reflected from the cord. The diseased organ was then removed and the orifice in the peritoneum closed. The remainder of the inguinal canal was then sutured with catgut, the skin with silk. Rubber drainage-tubes were inserted above and below, and a small portion at the upper part of the wound, which extended down to the peritoneum, was packed with iodoform-gauze. After its removal, the tumor was found to be a typical sarcoma. There will probably be a rapid recurrence of the growth, as it was impossible to extend the dissection higher without taking unwarranted risks.

A man, twenty-eight years old, was admitted to the hospital with a simple transverse fracture of the patella. In thirteen weeks, at the time of his discharge from the hospital, the dressings were removed and the fragments were found close together and firmly united. The patient was able to walk about with a fair degree of

motion. Several weeks later he fell, and although he experienced very severe pain in the affected knee, he walked around for two days before returning to the hospital. At the time of his second admission there was an enormous effusion into the joint with much discoloration, so that it was impossible to make out the exact nature of the injury until about ten days later, when it was found that he had refractured the lower fragment, while the original ligament remained intact, and was less than one-quarter of an inch long. In uncomplicated cases wiring the patella is objectionable, but in such a case as this—the patient being a laboring man—in which firmness of the joint was of special importance, the procedure became a most proper one.

An incision over the seat of the injury showed extensive extravasation of blood. The edges of the fragments required to be slightly freshened. After wiring, the wound was sutured with catgut and a small rubber drainage-tube inserted at each angle. A compress and bandage and a wooden posterior splint, with a footboard, completed the dressing.

CURRENT LITERATURE.

ACCIDENTS RESULTING FROM INTRA-UTERINE CAUTERIZATION WITH CANQUOIN'S PASTE.

Pichevin (*Nouvelles Archives d' Obstét. et de Gynécol.*, No. 2, 1891) concludes that the time has come to refute the arguments which have been advanced to legitimize the employment of a therapeutic measure which theory condemns in advance. He feels that it is necessary to furnish some facts, the eloquence of which is such that men of good faith and physicians desirous of the interest of their patients may renounce positively a proceeding which, as someone has written, is "a manifestation of atavism." Many who have employed caustics in the uterine cavity at some time in their practice are strongly opposed to this method of treatment to-day. Avan spoke of cauterizations of the cervix with the paste of the chloride of zinc, but was far from recommending this treatment. Bennet makes mention of the retractions which he had observed in women whose cervical canal had been cauterized. Scanzoni was strongly opposed to the employment of the caustic of Filhos, and Nonat reports great constriction of the utero-vaginal orifice following the use of Vienna paste. Bernutz and Goupil, after treating a young woman suffering from metritis by Vienna paste, reported an occlusion of the neck with menstrual retention. Emmet, Schröder, Martin, Mundé and others, all record themselves as opposed to cervical and intra-uterine cauterizations.

The advocates of the treatment by cauterization are strong in their opposition to the method of treatment by curetting the uterus. They claim that the latter is an operation which necessitates prolonged and rigid antiseptic precautions; that it places the surgeon under the necessity of making a previous dilatation; that it demands a chloroformization, which is "always formidable;" that it gives rise to a loss of blood which is at times very great; that it is a rather grave and complex operation; that it compels the surgeon to practise forcible depression of the uterus; that it is not successful when the uterus is retro-displaced; that it does not give better results than the other procedures which have been advanced for the cure of endometritis; and, finally, that it causes atresia. In answer to these propositions, Pichevin declares that *curage* of the uterus has been adopted by the immense majority of surgeons. Antisepsis, he says, is beyond doubt indispensable before, during and after the operation; slight dilatation is useful, but not indispensable. As for chloroformization, it may be omitted; but for the sake of the patient it has become the custom to resort to anæsthetization. The quantity of blood which escapes during and after the operation is absolutely insignificant. Moreover, hemorrhage—when it exists before the intervention—is arrested as by enchantment in the very great majority of cases. The abrasion of the uterine mucosa with a dull or cutting curette is not a complex operation. There is nothing more simple. Forcible depression of the uterus is not necessary. It suffices to fix the cervix with the aid of a small forceps. When the uterus is retro-displaced, the metritis will be cured under the influence of the curette, but it is necessary to replace the organ in its normal position. The abrasion of the uterine mucosa is not an infallible method of treatment for endometritis, but no procedure can be compared to it. As to subsequent atresia, Pichevin has never observed it in his practice.

On the other hand, the apostles of intra-uterine cauterization claim the following advantages for Canquoin's paste in the treatment of endometritis:

1. It is unnecessary to perform minute and prolonged antisepsis.

2. It is unnecessary to practise a previous dilatation.

3. It is unnecessary to anæsthetize the patient. The introduction of the stick of Canquoin does not occasion any pain. As to consecutive pains, they are rare, ordinarily but slightly marked, and of short duration.

4. The treatment does not necessitate a long rest. The patient is cured at the end of some days.

5. There is no hemorrhage produced by the cauterization.

6. Atresia does not result, or if it is noticed it is an exceptional occurrence. In any case, the cervical constriction is not special to this mode of treatment.

7. The intra-uterine cauterization is efficacious. The cure obtained from the stick or pencil is real and durable.

8. The innocuous nature of this intervention is undeniable.

9. The introduction of the stick or pencil of chloride of zinc into the uterus is simple and easy.

To these propositions Pichevin offers the following refutations: While Polaillon strongly advocates the employment of intra-uterine caustics, he admits that antiseptic injections are indispensable while the scar is forming and eliminating itself, and during all

the time necessary for the cure. Dumontpallier likewise says that the day of the operation being determined, frequent vaginal injections, about three *per diem*, should be made before the operation, employing a solution of sublimate 1 to 2000 or 1 to 3000.

Grandmaison and Bock recommend antiseptic washes for the external genitalia, with vaginal and intra-uterine injections of sublimate while the eschar is being cast off. Bock injects into the uterus tincture of iodine, perchloride of iron, or silver nitrate. It will thus be seen that the advocates of this method themselves largely employ antisepsis. As to the previous dilatation, Polaillon recognizes the fact that in certain cases it is necessary to introduce a laminaria tent, or to perform a slight dilatation with a uterine dilator. Grandmaison and Bock have also been compelled to dilate. Several of the followers of this method of treatment have testified to the severe pain which has been produced by the caustic agent. Reynier noticed that injections of morphine failed to relieve these sufferings. In ten operations Dr. Jacob has, with but one exception, noted very severe pains attendant upon cauterization. As far as rapidity of cure is concerned, the statements that the patients who have undergone cauterization are discharged in a few days cured are gravely erroneous. Bock, the Belgian defender of the system, says: "The time necessary for a cure will be from three weeks to three months." Jacobs, Polaillon and Batuaud report cases of violent hemorrhage following the separation of the eschar, thus confuting the claim of the adherents of cauterization as to the entire absence of bleeding. The efficacy of cauterization has not been demonstrated by the reports which have been published. In fifteen operations Deletrez reports but three cures, while Jacobs had ten relapses in ten cases. Neither is the method of treatment entirely free from unfortunate complications. In one hundred observations Dumontpallier reports four peri-uterine complications (two cases of pelvic peritonitis and two abscesses of the broad ligament). Following the application of caustics to the uterus, the state of the menstruation has been in several instances altered. Dysmenorrhœa and irregular menstruation, with increase of flow, have been noted by different operators.

CASE OF BILATERAL PNEUMOTHORAX.

Otto Lasius reports the case of a woman, twenty-seven years of age, with healthy husband, parents, brothers, and sisters. For a year and a half her capacity for work had diminished; she was no longer able to walk as rapidly and continuously as formerly, soon became tired, and was short of breath on slight exertion. Cough was at first slight, without expectoration, but subsequently became obstinate and accompanied by expectoration. In August, 1887, consolidation of the right apex, with beginning softening, was detected. The disease steadily progressed and a cavity developed. On January 10, 1888, the condition became suddenly worse; intense dyspnœa with a sense of constriction of the chest developed. Over the right anterior portion of the thorax, from the clavicle downward, a loud metallic percussion-note was present, which below became clearer. Over this area were heard loud metallic breathing with metallic tinkling. The same condition existed behind and above, while below there was pulmonary resonance and vesicular breathing. Nothing abnormal was detected in the left lung. On January 11th, the patient had a miscarriage of a fœtus, of six or seven months, which died in four hours. No tuberculosis was discovered at the autopsy. The patient was delirious during the following night. On January 13th, cyanosis became grave; orthopnœa set in; the respirations became 50; the pulse 120. January 14th, on the left side was developed a loud, metallic, tympanitic percussion-note, with complete absence of vesicular breathing; but anteriorly, on the side, and posteriorly, a higher-pitched sound was perceptible. In the second intercostal space, on the right side, a peculiar sensation was communicated to the finger; it was as though, directly under the skin, a viscid fluid mixed with air escaped, with a splashing sound, from a small opening. Death took place on January 20. At the autopsy bilateral pneumothorax was demonstrated.

The peculiar symptom noticed in the second intercostal space on the right side was due to the fact that the anterior surface of the right lung was adherent to the wall of the thorax in such a way that between it and the mediastinal pleura there was a cavity one inch long and four inches deep, which extended from the second to the fifth rib, and contained almost an ounce of fluid.—*Deutsche med. Wochenschrift*, April 9, 1891.

It is said that a Russian physician has brought a libel suit against a widower who had pasted on the tombstone of his lately deceased wife the last prescription he had given her, the day before her death.

"Of all that has been written and said as to what constitutes a gentleman, I like best that which we owe to Cardinal Newman, who says 'it is almost a definition of a gentleman to say he is one who never inflicts pain.' It matters not whether he be rich or poor, lettered or unlettered, well dressed or illy clad, he possesses most of that which goes to make up a gentleman who will not inflict pain."—Tyson, *Valedictory Address*, 1891.

"Much thought was expended nearly half a century ago by some of the ablest minds in the profession you have this day entered, in constructing a set of rules which should govern us in our relations to our patients, and especially to each other. The result was the Code of Ethics of the American Medical Association, a modern classic in literature which embodies the highest principles of conduct of men toward men. You will do well to study it closely, and to make it your guide; but you will learn from such study that the code of ethics is but an expansion of a much older and briefer code, 'Do unto others as you would that they should do unto you.' Than this there can be no safer guide, and if followed it will avoid most, if not all the misunderstandings which arise among medical men."—Tyson, *Valedictory Address*, 1891.

THE MEDICAL NEWS.
A WEEKLY JOURNAL
OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JULY 4, 1891.

INFECTIOUS BRIGHT'S DISEASE.

CLINICIANS have long felt that our knowledge of the etiology of acute Bright's disease is too scanty, and that a thorough review and re-investigation are necessary to bring the matter to a proper clearness. With the rapid advance in accurate methods of minute investigation it was but natural to expect a fuller knowledge of the causation of nephritis in its several forms, and in view of the late researches into the etiological factors of these diseases perhaps the time is now ripe for the expression of certain definite opinions or conclusions. The old idea—ascribing every case of acute Bright's disease to one of several causes, as, *e.g.*, to exposure, to preceding acute infectious disease, or to toxic agency—has been found too general and unsatisfactory.

So long as thirty years ago suspicion began to awaken, and BAMBERGER called attention to cases of idiopathic acute nephritis which suggested to him an infectious origin. Twenty years later LITTEN's attention was directed to the same point, and, with his better facilities, he was able to demonstrate bacterial foci in the kidneys, surrounded by patches of circumscribed inflammation, the vessels of the kidney being filled with microörganisms and the urine swarming with them. These are not to be considered as isolated instances of what Litten would call kidney-mycosis; the physician is constantly brought face to face with cases of this kind, cases which are not preceded by infectious disease, nor due to intoxication of any kind, and which arise independently of exposure. There are often violent and typical cases of acute nephritis, and these are they that, from the etiological point of view, puzzle us most. Here it is that investigation is needed.

As regards the nephritis following infectious disease it seems sufficiently proved by the investigations of Weigert, Gaffky, Cornil, Babes, Oertel and others, as well as by clinical observation, that the microörganisms, or the products of their activity, play an important *rôle* in the production of acute Bright's disease after pneumonia, erysipelas, typhoid, scarlet and several other infectious fevers. But it is to the other class of cases—those independent of infectious fevers—that we wish to direct attention. In this connection the careful studies of MANNABERG, at Nothnagel's clinic (*Zeitsch. f. klin. Med.*, xviii. 3 and 4), are of great interest. Whether or not we wish to go so far as he does, and ascribe to a particular streptococcus a definite etiological agency, it must be admitted that the bacteriological studies so closely coincide with well-observed clinical facts that great weight must be given to the theory of the existence of a form of mycotic nephritis. According to Mannaberg, his streptococcus possesses peculiar culture-properties, is constant in the urine and kidneys of certain cases clinically similar, disappears from the urine at the subsidence of the disease, and, when injected in pure culture into rabbits or dogs, gives rise to violent nephritis with occasional endocarditis—in other words, a blood-poisoning, with special involvement of the kidneys. These investigations are of interest in pointing out a way of study of the greatest promise. They must, of course, be repeated and confirmed by others before we can place complete confidence in them. As year by year our knowledge widens and the science of pathology is better developed, the long array of so-called functional diseases is lessened. At the same time we may expect such general agencies as cold to play a less prominent part in our conceptions of etiology. When of 105 cases of "idiopathic" acute Bright's disease, 64 present no history of cold or exposure, is it not necessary to assume other causal factors than those to which we have been accustomed? And what is more probable than infection? There are in these cases rapid onset, moderate fever, constitutional disturbances, kidneys and

urine full of bacteria—in short, a picture of disease in the highest degree suggestive of microörganismal infection. Added to the teaching of the study of individual cases and of bacteriological research, there is also the lesson of distinct epidemicity, as first observed by MIRCOLI and later by others. We therefore have the strongest ground for the theory that a definite form of infectious Bright's disease may yet be classed in our nosology.

RESUSCITATION BY OXYGEN.

LIEUT.-COL. HENRY ELSDALE'S experience with oxygen as a resuscitating agent, related in the May number of the *Nineteenth Century*, is evidently considered by him (and by the editor of the magazine), as something wholly new. While far from being a novel application of oxygen, the case appears to be unique in the extraordinary pressure employed. A man who had been attempting to empty the coal-gas from a balloon was found lying insensible, "having been breathing an atmosphere of coal gas for an unknown time." "No action of the heart could be felt," there was "no perceptible breathing," and to all appearances the man was dead. Pure oxygen being at hand, under a pressure of 1000 lbs. to the square inch, a tube connected with the reservoir was inserted into the man's mouth, and the gas turned on "as delicately as possible." Immediately the body began to exhibit writhings and convulsions, and in about ten minutes the man arose, well.

That wonderful physician who, a century ago, honored the chair of chemistry at Oxford, THOMAS BEDDOES, the worthy friend and co-laborer of Joseph Priestley, Erasmus Darwin, James Watt and Humphry Davy, demonstrated, among other things too little remembered by the profession, that kittens and rabbits that had inhaled oxygen for a certain time were more resistant to drowning, freezing or suffocating with irrespirable gases, than similar animals not saturated with oxygen.

Since the time of Beddoes, numerous observations proving the usefulness of oxygen in resuscitating the drowned or those poisoned with narcotic drugs or asphyxiating gases have accumulated. In J. SOLIS-COHEN'S treatise *On Inhalation*, we read that previously to 1847 it had been proposed by JACKSON and RICHARDSON that "wherever ether was administered oxygen should be kept in readiness to be inhaled in case of the occurrence of formidable symptoms, and that MR. HOOPER, acting on the suggestion, has supplied his inhaler with the means of furnishing oxygen at pleasure." DUCROY "proposed to make every patient awakening from chloroform-narcosis inhale oxygen, in order to rid him of headache and other inconveniences following the administration of that anæsthetic," and a very remarkable instance of recovery from chloroform-narcosis by the use of oxygen, which occurred at the New York Medical College, was published by ABRAHAMS in 1853.

Notwithstanding all this, and despite the fact that modern commercial enterprise has made it perfectly feasible always and everywhere to have the agent at command, there are many hospitals in which oxygen is not ready for instant use in emergencies, and it has not yet been recognized as an indispensable part of the outfit of life-saving stations. We believe that, not only in every clinic or private house where ether or chloroform is to be given should oxygen be under pressure, be instantly available, but that in hotels where persons are liable to be poisoned with coal-gas, and even in police-stations where persons poisoned by opium are likely to be taken, it should always be possible to find a reservoir of the gas. At seaside resorts, too, it should be part of the rescuing paraphernalia kept at the beach. A single life saved, and there would be many, would more than compensate for the cost. The pressure appears to have been a factor in Elsdale's case, and in any case the administration of oxygen should be accompanied with slow and regular movements of artificial respiration. B. W. RICHARDSON has shown that in artificial respiration the emptying of the lungs is ordinarily as important as the filling of them; and in his simple device of a double hand-bellows for that purpose, artificial expiration by suction plays an equal part with artificial inspiration by pressure.

THE ETIOLOGY OF CROUPOUS PNEUMONIA.

MODERN medical research has devoted considerable attention to the study of the etiology of disease. In the department of bacteriology discovery upon discovery, indicative of the causal relation between microörganisms and disease, has been made and verified. In the enthusiasm and excessive zeal which attend the promulgation of a new and promising doctrine, the indifferent student is apt to ignore important accessory conditions in a desire to reach a preconceived ideal.

At this day no unprejudiced mind will attempt to

controvert the validity of the germ-theory of disease; but we have not done in accepting the principle which the theory implies. Something more than a germ is requisite for the production of disease—not that the germ is a mere concomitant, but that, while perhaps the most important, it is but one of a number of elements, the association of which is the essential factor in the determination of a definite result; the soil must be fertile and the conditions propitious for growth and development. How else explain the immunity of some and the infection of others exposed to like influences under conditions apparently similar? Though we may never be able to explain the mode of action, it is well to recognize this association of etiological elements; while not detracting from the importance of the part played by microörganisms in the production of disease, we must not ignore or underrate the significance of other factors.

In a study of one hundred cases of uncomplicated croupous pneumonia, Brunner (*Deutsch. Archiv für klin Medicin*, Hefte 1 and 2, 1891) was able to determine that the disease is more common in males than in females; that most cases occur in the third and fourth decades of life; that those who lead active lives in the open air are predisposed; that the right lung is more commonly involved than the left; that the onset usually takes place in the morning with a chill; and that the disease is most prevalent in winter and in spring. Careful comparative observations upon the mean temperature, the mean humidity of the atmosphere, relative and absolute, the mean barometric pressure, as well as upon other meteorological conditions, in conjunction with the number of cases of pneumonia observed at different periods, revealed the fact that most cases occurred when the temperature was low, the absolute humidity slight, the relative humidity great, and the barometric pressure very high or very low. It appeared that those meteorological conditions that increased the physiological activity of the lungs favored the development of pneumonia.

The brief period of incubation which characterizes pneumonia may be explained by the almost constant presence of pneumonia-cocci in the air-passages, suitable extrinsic and intrinsic conditions conferring virulent properties upon a hitherto innocuous agent.

From many considerations it therefore appears that merely waging warfare against bacteria will not eradicate disease. The physical difficulties to be overcome alone render such a mode of treatment impracticable. A rational prophylaxis will have for its object the avoidance, as far as possible, of exposure to infection to deleterious influences of all kinds.

THE FRENCH BIRTH-RATE AND DEPOPULATION.

The Diagnosis.—The French census of 1886, the last that has been taken, showed an increase of 564,955, or 0.3 per cent., on the returns of 1881. In Germany the rate of annual increase is 0.7 per cent.; in Belgium, 0.9; in Spain and Italy, 0.6. Moreover, in France the birth-rate is diminishing, so that it will not be long before the death-rate will exceed the birth-rate. In 1856 the childless families constituted 17.3 per cent. of all families; in 1886, 20 per cent. The unmarried adults in 1856 composed 10.4; in 1886, 14.4 per cent. Patriotic Frenchmen—statesmen and philosophers—know what these figures mean, just as a physician knows the meaning of decreasing nutritional power in his patient.

The Treatment.—The forms of treatment proposed are many; all depend upon the special etiology ascribed to the disease by the friends of the patient. Sexual immorality is by some thought to lie at the bottom of the mischief; by others the blame is laid upon the law of inheritance; by still others, to the use of tobacco, etc. Monod, Director of the Public Health, says that proper and feasible sanitation would certainly save 130,000 lives annually. Brouardel holds the State responsible for 14,000 lives annually sacrificed because vaccination has not been made compulsory. All, however, are agreed that the State shall be called in as physician-in-charge. Taxation of bachelors, rewards to fathers of large families, and many like proposals do not seem to reach the root of the matter. With a sublime indifference to the ethical aspect of the question — nay, even with most noteworthy encouragement of sexual immorality, the French Academy has offered its services as consultant, and at its last meeting unanimously, *and with applause*, passed the following resolution:

"That in each department there shall be established at least one asylum for the care of pregnant women during the last months of gestation; that if she wishes it each woman shall be so cared for that absolute secrecy shall be preserved as regards her entrance, stay and delivery in the establishment and as to her departure from it; that all adminis-

trative inquiry as to the place of residence and identity of the patient shall be interdicted; and, finally, that financial aid shall be given to such women as from insufficient means are unable to bring up their children."

In encouraging illegitimacy, the Academy evidently accepts the Jesuit maxim that the end justifies the means, and is also of the opinion that quantity is of far more value than quality. To an outsider it all appears more like stimulation than nutrition, and we hesitate about giving a definite prognosis.

SOCIETY PROCEEDINGS.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of June 3, 1891.

THE PRESIDENT, DR. L. C. GRAY, IN THE CHAIR.

DR. M. A. STARR read a paper on "The Cerebral Atrophies of Childhood, with Special Reference to Surgical Treatment." He devoted himself to a particular class of cases—viz., the cerebral diseases of infancy and childhood. Certain cerebral diseases of infancy give rise to definite symptoms, constituting three types of clinical cases: 1. Cases of hemiplegia, with or without athetosis; 2. Cases of mental defects of various grades; 3. Cases of sensory defects of various kinds. Since epileptiform seizures, *petit mal* or *grand mal*, are frequently encountered in any of these forms, and might be the symptom in regard to which advice was sought, the discussion must also include the surgical treatment of non-traumatic organic epilepsy in children. In cases of the first class the symptoms are unilateral paralysis, suddenly developed, after a series of convulsions, attended with elevation of temperature and other febrile symptoms, followed by loss of consciousness of varying duration; after the subsidence of the active symptoms of onset gradual improvement in the paralysis follows. Ultimately a stationary condition is reached, in which voluntary and automatic movements of the face are scarcely affected; speech, if lost, is usually regained; the arm is quite seriously paralyzed, the fingers being stiff and awkward, and sometimes in constant, slow, involuntary motion; the leg is held rather rigidly, so that the child limps in walking, and sometimes has club-foot. In all cases the paralyzed limbs are found to be affected in growth and development, being smaller, colder, stiffer and weaker than their fellows; the reflexes are exaggerated, but the electrical reactions are not quantitatively changed; sensation is normal. This condition remains through life as a permanent defect. In over one-half of the cases of this kind epileptic attacks are of frequent occurrence. The cases which date from birth must be divided into those in which there was evidence of traumatism during labor, and those in which there was nothing about the delivery sufficiently unnatural to awaken suspicion of trauma. In the former, cerebral hemorrhage (usually meningeal) is the cause of the symptoms. In the latter it is probable that an intrauterine encephalitis or some unknown cause has prevented the development of the fœtal brain. The degree of spontaneous recovery in any case could be pretty well determined by an examination at the end of the second year; complete recovery has never occurred. In organic epilepsy the fits are more likely to be frequent and severe than in idiopathic epilepsy. These attacks do not destroy life, but of course render it a burden, so that almost any means of relief is welcomed. Cases of the second class present mental defects rather than physical symptoms—defects which cannot be eradicated. Cases of the third class present no motor or mental deficiencies; they are capable of training, but display defects of sensory perception, indicative of gross cerebral disease. Many cases of deaf-mutism belong to this class, as do some cases of hemianopsia. Dr. Starr related the history of a little girl, twelve years old, who had suffered all her life from frequent attacks of *petit mal* and occasional attacks of *grand mal*. She had never been able to see objects approaching her from the left side. From the mother it was learned that the child had been delivered with much difficulty; that the labor had been protracted; that the head was misshapen and had a large caput succedaneum posteriorly. Perceptible flattening of the skull over the right occipital region could be detected. The visual fields were contracted. It is reasonable to suppose that there existed defective development of the right occipital lobe of the brain, involving the cortex and the subcortical tract. Wilbran has shown that a purely cortical lesion produces symmetrical defects in the visual field, while subcortical lesions produce asymmetrical defects. In the case reported the pupils responded to light thrown upon the blind field of the retina—hence the lesion was not in the optic tract. There was no hemianæsthesia or hemiplegia—consequently the lesion was not in the thalamus or near the internal capsule. The patient was brought for treatment for epilepsy, and it was important to decide as to the possible benefit of surgical interference. A solution of the problem of operative treatment must be based upon two considerations: (1) The pathology of the cases, and (2) upon the results of experience in cases in which such operations had been done. Differences in clinical types depended upon differences in situation of the lesion. The various processes of disease had as a fairly uniform result a condition of atrophy with sclerosis of the brain. In cases of the first type the sclerotic atrophy involved the motor area, the central convolutions and their immediate vicinity, including the tract arising from them, and usually the basal ganglia as well. In cases of the second type the sclerotic atrophy involved the anterior portion of the brain, and sometimes the entire hemisphere, to a greater or less extent. In cases of the third type the sclerotic atrophy involved the posterior and lateral parts of the hemispheres. The hypothesis that the lesion depended upon interference with the blood-supply of the part (since in some cases the atrophy is limited to the region supplied with blood by one arterial trunk) is weakened by the fact that at autopsies it is rare to find vascular lesions in the brains of infants. The pathogenesis of these defects is as yet quite obscure. From the records of operations performed in six cases of the first clinical type, it is evident that this method of treatment offered no relief. In the second type the pathology contra-

indicated operation. As to the third type, with sensory defects, there were no facts of surgical import to present; but, judging from the pathological resemblance between it and the first two classes, there was no reason to expect any different result from surgical treatment. The conclusions to be drawn are: 1. That in infancy and childhood mental defects, hemiplegia and sensory defects of years' duration are usually due to irremediable atrophy of the brain; 2. That in such cases surgical treatment cannot afford any relief, for there is probably no increase of intra-cranial pressure to be relieved, while the pathological state is one which is not susceptible of treatment; 3. That the sudden onset of motor, sensory or psychic symptoms in childhood, while awakening a suspicion of cerebral hæmorrhage, is not a positive indication, and cannot be made the basis for an operation, unless many other facts make the diagnosis clear; 4. That the occurrence of epilepsy in such cases might be made the basis of an operation, for while the epileptic attacks are of organic origin and will persist, their frequency may be much diminished. In such cases the opening in the skull should not be filled with bone. The existence of a movable connective-tissue valve of scalp covering the opening in the skull with varying tension, may have something to do with the cessation of the fits. Great caution is to observed in recommending surgical interference in the class of cases which belongs to cerebral atrophies.

Dr. B. Sachs thought that there was hope for the cases described if they could be operated upon at the time of the initial lesion, before degenerative changes had taken place. It is worse than useless to operate in cases of sclerosis or porencephalus. Secondary degeneration follows in many diseases of the brain, but not in all cases. Much good is accomplished by the puncture of old hemorrhagic cysts. The frequency of epileptic attacks has been very much diminished by this procedure. In the radical treatment of cerebral atrophies, no good can result unless the entire diseased area is removed. The patient might be left with a paralysis, but with a cure of the epilepsy. Which of the two were the greater evil would have to be determined by those most interested. When a sclerotic condition was not thought to exist, and it was supposed that the initial lesion could be attacked, an operation might be done; but it must be borne in mind that children do not bear surgical operations upon the brain as well as do adults.

CORRESPONDENCE.

PATENT MEDICINES; QUACKERY; INCOMPETENCE AND FRAUD IN THE DRUG TRADE.

To the Editor of The Medical News,

Sir: From the above heading you will instinctively think of the wordy denunciation, and the language of impotent abuse, so frequently hurled at quacks and quackery. You will also doubtless call to mind the addresses and resolutions of medical society anniversaries, in which the quack, metaphorically speaking, is cornered, and so to speak, punched in the ribs, and otherwise maimed and maltreated. But this so-called "doing-up" of the quack has not injured him very seriously. On the contrary, it has served to increase his strength and to prolong his days upon the earth. The object of all such efforts has looked in the right direction, and it is not my purpose to criticise it. But these agencies have had no very decided effect, and in the nature of the case they are not likely to influence or mould public opinion to any great extent.

In recent years attention has been turned to law-making, hoping thereby to restrict and control medical and pharmaceutical education and practice in such a way that the evils complained of may be finally abolished. This plan looks to a thorough purging of the body professional by means of legislative enactments, the application of which the executive departments, or more specifically the Governors of the respective States, are to be entrusted with. This method has some advantages. It is a very simple and summary manner of obtaining some sort of remedy for the evil. The average legislator and Governor are fond of making laws and increasing their political prerogatives, and will help our medical reformers along this line of action. These gentlemen, however, either forget or ignore the fact that the American medical profession many years ago tried this plan of dealing with the evils of quackery and incompetence in our ranks, and failed. And they forget that under a republican form of government all legislation directed against any popular error or crime whatever, will in the end be only so much *brutum fulmen* unless sustained by public opinion, and that popular evils will be corrected and popular crimes punished, law or no law, if public opinion decrees it. Whatever legislation, then, may be secured in the future, it will wholly and ingloriously fail in its avowed purpose, unless public opinion thoroughly indorses it.

The plan which I wish to propose looks to taking the people thoroughly into our confidence and making them our allies. In a word, it is as follows: After careful chemical analysis, the publication to the world of the secrets of the composition of all popular patent medicines, and also the testing of all drugs and pharmaceutical preparations suspected of not being up to the official standard of strength and purity.

A necessary part and prerequisite of this scheme is the establishment of a suitable but not very expensively equipped chemical laboratory centrally located, supported by and under the joint management of the American Medical and the American Pharmaceutical Associations, with publication of its work. The mystery of the composition of a patent medicine is the chief reason of its great sale, and the United States patent laws guarantee that the secret shall be kept. But if the Government could be induced to repeal these laws and require the composition of every nostrum to be published on the label or wrapper of the package or bottle in which it was dispensed, the ruin of the trade would follow. If, however, the two above-mentioned associations could, by combining their resources of money and skill, discover and divulge to the world these secrets, it would not be long before public opinion would demand some action on the part of Congress restricting and regulating the evils of the patent medicine trade. Nor would the resulting benefit of such a supervising control and influence over the regular drug trade be barren

in results. In time it would bring about the assurance that drugs and pharmaceutical preparations should be of a uniform standard of purity and strength.

Anyone, physician or druggist, could then submit drugs or preparations to the examination of this competent and fair tribunal, and errors or frauds would there be corrected, discovered and exposed. And particularly would the country physician, remote from the great manufacturing and importing centres of the country, hail with delight the institution of a single censorship, which would at once insure him the certainty of pure drugs and result in a greatly needed improvement in the drug trade.

Geo. Cowan.

Danville, Ky., June 18, 1891.

REVIEWS.

A Text-book of Practical Therapeutics, with especial reference to the Application of Remedial Measures to Disease and their Employment upon a Rational Basis. By Hobart Amory Hare, M.D., B.Sc., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Physician to St. Agnes's Hospital and to the Medical Dispensary of the Children's Hospital; Laureate of the Royal Academy of Medicine in Belgium, of the Medical Society of London, etc.; Secretary of the Convention for the Revision of the Pharmacopœia of 1890. Second edition, enlarged and thoroughly revised. Philadelphia: Lea Brothers & Co., 1891.

If the sale of a large edition of a work on practical therapeutics, and its adoption as a text-book by a number of medical colleges, within the short space of six months is any indication of its merits and of its value as a practical guide in the treatment of disease, Prof. Hare is to be congratulated upon having given the profession such a work. The appearance of new works and successive editions of old ones is necessitated by the rapid advance in our knowledge of the physiological action of drugs and their application for the cure of disease. Chemists are continually producing new compounds whose physiological actions are immediately investigated; clinicians eagerly scan the conclusions and seek out the indications for their use. While the results of individual observers are recorded in the periodical medical literature of the day, it becomes necessary at intervals for someone skilled in a knowledge of physiological methods, and possessing at the same time a general therapeutic training, to gather the results of different investigators, to determine their comparative value and present them in a compact form, that they may be readily accessible. The well-known investigations upon the physiological action of drugs, and the clinical experience of Prof. Hare, abundantly qualify him for such a task.

The present work is divided into four parts, viz.: I. General Therapeutic Considerations. II. Drugs. III. Remedial Measures other than drugs. Foods for the Sick. IV. Diseases. Tables of doses and remedies. Tables of relative weights and measures in the metric and apothecaries' systems. Index of drugs and remedial measures. Index of diseases and remedies.

In Part I. the author briefly and concisely discusses, among other topics, the modes of administering drugs, their dosage, the idiosyncrasies of patients, the incompatibilities of drugs, the indications and contra-indications for their use, etc. He interjects a large number of valuable and practical suggestions which must ever be kept in mind if the student or practitioner expects to obtain the best possible effects after their administration. It is a neglect of these primary facts which is the cause of so much disappointment, and which leads the practitioner to doubt the efficacy of remedies.

Part II., embracing nearly three hundred pages, is taken up with a consideration of the properties of drugs, their physiological action and therapeutical uses.

The author makes no attempt at a classification of drugs, but arranges them in alphabetical order, according to their English names. While it is well known that in the present state of pharmacology an exact and scientific classification is almost impossible, nevertheless a grouping together of those drugs which resemble each other in their effects on the system, both in health and disease, is not only possible but desirable. It would simplify the study of this subject and thus lighten the task of the student.

In the published reports of the physiological action of drugs by special investigators there is often much that may be of interest scientifically, but practically is of little value. Dr. Hare, who has had a large experience in investigating the action of drugs, has exercised good judgment in selecting and recording here only those effects upon the different physiological mechanisms which are essential to the therapeutist wishing to administer remedies intelligently. In this respect the work before us is worthy of commendation, because a thorough acquaintance with these facts, and the administration of drugs in accordance with them, is the only way in which a rational system of therapeutics can be established.

In Part III., in addition to a consideration of the therapeutic uses of heat, cold, antisepsis, disinfection, venesection, counter-irritation, etc., the author has added to the second edition a short account of the methods of employing the rest-cure—devised by Dr. S. Weir Mitchell, and which has been so successful in the treatment of a great variety of nervous diseases. The treatment by the method of suspension also receives a brief consideration. To those familiar with the difficulties of alimentation in various forms of disease, the introduction in this work of formulæ for the peptonization of milk, beef, gruel, and the diet lists of the Children's and University hospitals, will be considered judicious, and, if faithfully carried out, will not only enable the physician to combat successfully many pathological conditions of the alimentary canal, but also to retard the progress of many general wasting diseases.

In Part IV. the author has devoted nearly two hundred and fifty pages to the treatment of a large number of the more familiar diseases, and brought together under each disease the various drugs and remedial measures which in his experience and in the experience of others have been found most successful. Symptoms and pathology in these sections have been omitted, except in so far as they might be necessary to a correct application of the drugs. Numerous prescriptions will be found in this part, which, if carefully considered, will

at least teach young practitioners the value of combining two or more drugs for the purpose of obtaining the best possible results.

In the preparation of the first edition of this work errors of statement and fact unavoidably crept in, some of which were pointed out in the various published reviews. These, so far as possible, have been eliminated and the entire text has been subjected to careful revision. Upon any subject about which there is so much diversity of opinion as the action of drugs and the treatment of disease, it is very difficult for a writer to make statements which will not be antagonized and criticised by someone, and the only course to pursue is to think and write according to the knowledge and experience which one possesses. This we believe the author of this work has conscientiously done. Successive editions will no doubt be called for, which will contain all the true acquisitions to modern therapeutics.

A Practical Treatise on Diseases of the Skin. By Henry G. Piffard, M.D., Clinical Professor of Dermatology, University of the City of New York, etc.; assisted by Robert M. Fuller, M.D. With fifty full-page original plates and thirty-three illustrations in the text. New York: D. Appleton & Co., 1891.

The key to the author's mind in the preparation of this work may be found in the preface, where it is stated that he has endeavored to present the subject "in the most practical manner and with the fewest possible words." There is an absence of theoretical and controversial discussion, and to a considerable extent even of pathological histology. The statements throughout are brief and concise, and in some instances at a sacrifice of the subject-matter. The chapters are for the most part short, many of them too short, we think—some of the more important diseases, as for example, comedo and tinea sycosis, receiving barely a dozen lines. Other well-known diseases, such as ecthyma and pityriasis rosea are altogether omitted from both description and representation. From these observations it will be noted that the work cannot be accepted as a systematic and complete treatise on diseases of the skin. At the same time, while we would have been pleased with a fuller and more complete exposition of the subject, we highly appreciate the work as it stands, and especially the valuable personal experience of the author, which comes out strongly on every page. A few practical points may be referred to. In the treatment of eczema of the scrotum the best three methods are scarification, sometimes followed by surprising relief; the galvanic current; and the application of liquor potassæ. In eczema of the anus the fine point of the Paquelin cautery at white heat is well spoken of; and in acute eczema of the leg and in eczema of the vulva, solution of peroxide of hydrogen is greatly esteemed. As a substitute for tar the following formula is recommended: Salicylic acid, grains x to xx; oil of lavender, ʒiij; oil of citronella, ʒj; oil of eucalyptus, ʒij; castor oil, ʒij. This is especially useful in eczema of the scalp, where tar would be indicated. In general the value of internal treatment is insisted on, and excellent advice is given concerning the use of that potent but dangerous drug arsenic, than which no remedy is more abused in the treatment of skin diseases. The view obtains even at this date, and this too among the best class of general practitioners, that arsenic is generally useful over the whole range of cutaneous diseases: as a result much positive damage to the skin and whole organization is not infrequently wrought. Probably in the majority of cases where used it proves more injurious than beneficial both to the skin and to the tissues generally.

We note that lichen ruber and lichen planus are regarded as distinct diseases, the distinguishing marks of lichen ruber being that the lesions are acuminate and not flattened, lack the central depression, and rarely undergo spontaneous resolution.

Under pityriasis rubra two diseases are described separately, viz., pityriasis rubra (Devergie), and pityriasis rubra (Hebra).

A long chapter is devoted to the new disease called psorospermosis, the author arriving at the conclusion, as concerns the pathology of the disease, that the so-called molluscous bodies, or psorosperms (so far as molluscum contagiosum is concerned), are not animal parasites, but are simply rete cells undergoing a species of corneous degeneration.

The plates consist of photographs taken by the aid of artificial light, which Dr. Piffard regards as preferable for this purpose to ordinary light. The pictures vary in size, some being almost as large as life; they also vary in degrees of perfection, many being remarkably good, while others fail altogether to portray the disease. The best, in our opinion, are eczema of the sole; eczema of the knees; psoriasis resembling eczema; seborrhœa kerativa; icthyosis; and alopecia areata.

We heartily commend the atlas to the profession, feeling that it will prove a valuable addition to the library. The author's long-established reputation is alone sufficient to recommend it to all interested in dermatology. It is a handsome royal quarto volume of one hundred and fifty-six pages, with large clear type, and is printed on heavy, highly calendered paper.

Practical Pathology and Morbid Histology. By Heneage Gibbes, M.D. Philadelphia: Lea Brothers & Co., 1891.

Dr. Gibbes's established reputation as a master of the technique of microscopy would lead us to anticipate a work of great value. In this we are not disappointed. The chapters devoted to this subject are models of completeness, condensed in such a manner as to render them of the greatest possible value to the laboratory worker. The author's methods of hardening, section-cutting and staining are given in detail, and are accompanied by valuable formulæ for reagents, etc. Celloidin and paraffin infiltration are not mentioned, both of which, in other hands, have proved valuable methods. The method of differential staining of the central nervous system (Weigert's) is not given. Dr. Gibbes very wisely insists that clinical histories be sent to the laboratory with the material to be examined. Many clinicians seem to think that the more their specimens are enshrouded in mystery the more interest the laboratory worker will find in them. The reverse, of course, is true. The chapters on Practical Bacteriology would have been vastly improved by descriptions of tube-plates, bottle-plates, and methods for anaerobic culture.

The chapters on Morbid Histology give wide scope to the author's marvellous skill in photo-micrography, and some beautiful reproductions are made by the photo-electrotype process. We cannot, however, praise the process work, as detail, sharpness of outline and penetration are wanting in nearly all cases.

In theory, Dr. Gibbes belongs to that class of pathologists who ignore the generally accepted microbic origin of disease, and, as a result, his ideas of inflammation, suppuration, tuberculosis and allied conditions are at variance with those of the majority of the profession. The deposit of lime salts in inflammatory and similar processes is discussed as "Calcareous Degeneration." Amyloid infiltration is also considered a degeneration. The definition of neoplasms is faulty, as all its predecessors have been. In fact, it seems to us that, had Dr. Gibbes devoted the space of this portion of the book to a more extended discussion of technique, embracing the examination of the blood, etc., he would have enhanced the value of his work.

The chapter on Photography is replete with excellent formulæ and directions. The necessary dark-room appliances, as well as the room itself, have no mention. The photographs of bacteria are superb, and the remarks upon lenses the most appropriate we have seen.

Taken as a whole, the volume is one of the best upon technique that we possess, and no laboratory should be without a copy.

Materia Medica and Therapeutics, with especial reference to the Clinical Application of Drugs. By John V. Shoemaker, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine, and Clinical Professor of Diseases of the Skin in the Medico-Chirurgical College of Philadelphia; Physician to the Medico-Chirurgical Hospital; Member of the American Medical Association, of the Pennsylvania and Minnesota State Medical Societies, the American Academy of Medicine, the British Medical Association, Fellow of the Medical Society of London, etc.

Vol. II. of a Treatise on Materia Medica, Pharmacology and Therapeutics: being an independent volume upon Drugs. Philadelphia and London: F. A. Davis, 1891.

The first volume of this work on materia medica and therapeutics was published several years ago and was the result of the conjoint labors of Prof. Shoemaker and Dr. John M. Aulde. This second volume, which has just made its appearance, has been the work of Prof. Shoemaker alone and is regarded by him as an independent work devoted to the consideration of drugs, their pharmaceutical preparations, their physiological actions and therapeutical uses.

The author has devoted over 600 pages to the consideration of an enormous number of drugs, many of which, however, have long since ceased to play any part in the modern treatment of disease. According to the announcement each drug is considered in alphabetical order "for convenience of reference for either physician, dentist, or pharmacist, when immediate information is wanted concerning the action, composition, dose, or antidote for any officinal preparation or new remedy."

The description of the physiological effects of drugs is complete and accurate and represents the existing state of pharmacological knowledge. In addition to the ordinary and well-known officinal drugs, Dr. Shoemaker has collected the latest and most reliable information as to the action and uses of all the noteworthy new remedies such as tuberculin (Koch's lymph), spermine (Brown-Séquard), exalgine, bromoform, thiol, pyoktanin and many others.

The therapeutical uses of this long list of drugs is quite extensive, the author apparently having but little sympathy with modern therapeutical nihilism; a great variety of prescriptions and practical formulæ are found everywhere throughout the volume, which are supposed to represent the latest achievements of clinical medicine.

Text-book of Ophthalmoscopy. By Edward G. Loring, M.D. Edited by Francis B. Loring. Part II. New York: D. Appleton & Co., 1891.

The first part of this work, which appeared in 1886, described the normal eye, the methods of determining refraction, the diseases of the media and the theory of the ophthalmoscope. With the exception of a remarkable indifference to the value of retinoscopy, it is a splendid presentation of the subjects enumerated. The volume before us, which has been published under the editorship of Dr. Francis B. Loring, discusses diseases of the retina, optic nerve and choroid, their varieties and complications, and, in spite of the fact that final revision on the part of its author was not possible, is a remarkable book, clear, thorough and replete with new facts and old facts presented in a new light. The disturbances of the vascular system of the eye-ground and the various types of inflammation of the retina occupy more than one-half of the volume. Space does not permit us to take up in detail the quite original method in which this particular field of ophthalmoscopy has been occupied, but we feel that the title of "text-book" does not give an adequate idea of the subject-matter. It really is composed of a series of monographs in which, with singular skill, Dr. Loring has carefully digested the literature of the subject and garnished it with his own admirable observations. Diseases of the optic nerve follow, not quite so thoroughly treated, the presentation of the matter included under the title "Glaucomatous Excavation" being somewhat disappointing. Affections of the choroid, so far as the subject goes, is capital reading, but evidently far from complete. Except in general reference to what the book contains we have not attempted to give an analysis of its subject-matter, which we think the editor was most wise to present without addition and without correction. Practising ophthalmologists might often find statements throughout these pages with which they cannot agree—statements, however, that one would expect from a strong man like the late Dr. Loring, whose vast experience, accurate observation and positive opinions are necessarily presented with the vigorous directness of one possessed of the courage of his convictions. It seems to us that the value of this text-book is that it not only furnishes what is best in the portions of ophthalmology to which it relates, but also what was best in the lamented author's own observation—observation that gave him his high rank among scientific physicians.

Historical Sketch of the University of Maryland. By E. F. Cordell, M.D. Baltimore: Isaac Friedenwald, 1891.

One of the most interesting portions of medical history in the United States is connected with the foundation of its medical schools and with the lives of their professors. Dr. Cordell, in a peculiarly happy style, has written about those men who were prominent half a century ago in the medical history of Maryland, and who were naturally connected with the Medical Department of its University. In addition to the ordinary biographies of the Faculty, the author has woven into his narrative enough of the private life of each physician to give one an interesting insight into the ways in which things were done in Maryland fifty years ago by those who were recognized as being in the forefront of social life.

At the end of the book there is a complete list of the graduates of the institution, which is completed by an appendix containing a list of all the provosts, deans, and professors. The engravings and other likenesses which are scattered through the work are unusually good, and the author and publisher are to be congratulated upon the pleasant appearance of their product.

NEWS ITEMS.

Resignation of Dr. James B. Walker.—At a stated meeting of the Faculty of the Woman's Medical College of Pennsylvania, held May 16, 1891, the following action was taken in connection with the resignation of the chair of Practice of Medicine by Dr. James B. Walker:

"The Faculty has received with sincere regret the announcement of the resignation by Dr. James B. Walker of the chair of the Practice of Medicine in this College.

"Dr. Walker held this chair during a period of twelve years, and continuously merited and received the highest appreciation of his colleagues in the Faculty, of the associate teachers, and of the students.

"In all the relations incident to the position he occupied he demonstrated his urbanity, integrity and unusual ability.

"He enthusiastically and successfully fulfilled not only the duties directly pertaining to his connection with the College, but he was also very active and successful as a clinical lecturer at the Woman's Hospital.

"As one of the physicians to the Philadelphia Hospital he greatly enlarged his usefulness to our students by gratuitously extending to them invaluable bedside instruction in that hospital.

"He contributed to the harmonious working of the Faculty and rendered material assistance in advancing the prosperity of the College.

"The exactions of his extensive private practice have influenced Dr. Walker to present his resignation. The Faculty extends to him its best wishes for his continued prosperity and happiness."

To Prevent the Importation of Disease.—Surgeon-General Wyman, of the Marine-Hospital Service, has suggested, as a precaution against the importation of smallpox and other diseases by means of the baggage of immigrants, that the States for which the immigrants are destined be furnished with a list of persons who come in vessels which have been or are infected or which come from ports at which contagious diseases prevail.

The Second Congress for the Study of Tuberculosis will be held at Paris from July 27th to August 2d. The following subjects will be discussed: (1) The Identity of Tuberculosis in Man and Tuberculosis in Cattle, Fowl and other Animals; (2) Association of Morbid Conditions Dependent upon Bacteria with Tuberculosis; (3) The Treatment of Tuberculosis in Hospitals; (4) The Prophylaxis of Tuberculosis in Man and in Animals; (5) Means of Destroying the Tubercle Bacillus without Injury to the Organism, with Reference to the Prophylaxis and Treatment of Tuberculosis in Man and Animals.

Dr. Daniel G. Brinton will represent the American Philosophical Society at the Congrès International d'Anthropologie et d'Archéologie Préhistorique, to be held at Moscow.

Dr. Gabriel Anton, of Vienna, has been elected Professor Extraordinary of Neurology and Psychiatry at the University of Innsbruck.

Royal Academy of Science of Vienna.—Meynert has been elected a corresponding member and Exner an ordinary member of the Royal Academy of Science of Vienna.

The Fourteenth Italian Medical Congress will be held at Siena, August 16, 17 and 18, 1891.

State Board of Health of Kentucky.—At a recent meeting of the State Board of Health of Kentucky, held at Louisville, it was

"*Resolved*, That the Secretary be instructed to place upon the list of medical colleges, the diplomas of which are to be certified to and indorsed for registration under the laws of this State, only such colleges as shall, after the session of 1891–2, exact of matriculates and graduates a minimum of requirements not lower than that required by the American Medical College Association."

The Colorado State Medical Society held its twenty-first annual convention at Denver, Col., June 16, 17 and 18, 1891. A most elaborate programme, including the presentation of a large number of scientific papers, was carried out.

The American Society of Microscopists will hold its fourteenth annual meeting at Washington, D. C., August 10–14, 1891.

Midwives in Hungary.—Professor William Tauffer, of Budapest, considers midwives largely responsible for the high mortality among lying-in women and newborn children in Hungary.

Madame Pauline Malcy has bequeathed $8000 to the Association des Médecins de la Seine, for the relief of widows and daughters of medical men who have left their families in straitened circumstances. Madame

Malcy has also bequeathed $4000 to the French Academy of Medicine, for the foundation of a prize for the best work on a subject connected with mental disease.

Convalescent Home.—An anonymous donor has presented to the county of Surrey, in England, a convalescent home for males at Seaford, Sussex. The cost of erection was $75,000; an endowment of $50,000 has been set aside. The house will accommodate fifty patients. The Duke of Cambridge is the president of the institution; the Duke of Connaught and the Duke of Teck, vice-presidents.

The Croonian Lectures of the College of Physicians of London have been postponed, owing to the illness of Dr. Burdon Sanderson, the lecturer of this year.

The Inter-continental American Medical Congress.—At the meeting of the American Medical Association, held at Washington, May 5, 1891, preliminary arrangements were made for an Inter-continental American Medical Congress.

A Committee on Nominations was instructed to nominate one member for each State and Territory, and one each from the Army, Navy and Marine-Hospital Service, to constitute a committee to effect a permanent organization of the proposed Inter-continental American Medical Congress, and to determine the time and place at which it should be held.

The committee appointed by the American Medical Association to effect a permanent organization of the Inter-continental American Medical Congress, met at Washington, May 7, 1891. Dr. Charles A. L. Reed, of Cincinnati, Ohio, was elected Chairman; Dr. J. W. Carhart, of Lampasas, Texas, Secretary; Dr. I. N. Love, of St. Louis, Mo., Treasurer.

The officers were appointed a special committee to draft a constitution, and to report at an adjourned meeting of the general committee to be held at St. Louis, Mo., Wednesday, October 14, 1891, when the time and place of meeting of the Congress will be decided, and permanent officers be elected.

Francis Peyre Porcher, M.D., LL.D.—At the recent commencement of the South Carolina University of Columbia, the honorary degree of Doctor of Laws was conferred upon Professor Francis Peyre Porcher, the distinguished pharmacologist.

Medical Society of New Jersey.—The one hundred and twenty-fifth annual meeting of the New Jersey State Medical Society was held at Long Branch, June 23d and 24th. The President, Dr. James S. Green, delivered the annual address. His subject was, "A View of Modern Surgery from the Standpoint of a General Practitioner." Dr. Edgar Holden, of Newark, read a paper on "Tuberculosis." Dr. E. J. Marsh, of Paterson, was elected President for the ensuing year and William M. Pierson, of Orange, Secretary. The next meeting will be held at Atlantic City in June, 1892.

The Vis Medicatrix is the name of a new publication, to be issued bi-monthly as the journal of the Iowa State Medical Society, and to be devoted to human and comparative medicine. Woods Hutchinson, A.M., M.D., is the editor, and L. H. Pammel, B.Agr., and S. Stewart, M.D., D.V.M., are his associates. The first number bears the date of June 1, 1891, and contains the proceedings of the Iowa State Medical Society, a number of terse editorials, a department of diseases of animals, under the charge of Dr. Stewart, and a department of plant-diseases and bacteriology, under the charge of Professor Pammel. Fifty-five pages of reading matter are presented in excellent form and typography.

Correction.—In the memorandum on "Methods of Staining Bacilli," by C. F. Gardiner, M.D., in THE MEDICAL NEWS, June 13, 1891, p. 668, the quantity of methyl-blue in the second formula given should be fifteen grains, and not, as stated, two ounces.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 23 TO JUNE 29, 1891.

SKINNER, J. O., *Assistant Surgeon.*—Upon the abandonment of Fort Davis, Texas, will proceed to Fort Clark, Texas, and there take station.

EWING, C. B., *Assistant Surgeon.*—Is granted leave of absence for one month.

CARTER, EDWARD C., *Assistant Surgeon.*—Is relieved from duty at Fort Walla Walla, Washington, and assigned to duty at Fort Canby, Washington.

By direction of the Acting Secretary of War, the leave of absence on surgeon's certificate of disability, granted JULIUS H. PATZKI, *Major and Surgeon*, in S. O. 99, May 1, 1891, from this office, is extended two months on surgeon's certificate of disability.—Par. 15, *S. O. 142, A. G. O.*, June 22, 1891.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JUNE 27, 1891.

HALL, J. H., *Surgeon.*—Detached from Naval Station, New London, and ordered to Naval Hospital, Chelsea, Mass.

ATLEE, L. W., *Passed Assistant Surgeon.*—Detached from nautical School-ship "Saratoga," and wait orders.

STEELE, J. M., *Passed Assistant Surgeon.*—Ordered to nautical School-ship "Saratoga."

LUNG, G. A., *Assistant Surgeon.*—Ordered to Naval Station, New London, Conn.

PAGE, J. E., *Assistant Surgeon.*—Detached from Naval Hospital, Mare Island, and ordered to the "Independence."

PIGOTT, M. R., *Assistant Surgeon.*—Detached from U. S. Receiving-ship "Independence," and ordered to Naval Hospital, Mare Island, Cal.

FIELD, J. G., *Assistant Surgeon.*—Detached from U. S. S. "Omaha," and granted three months' leave of absence.

BRATHWAITE, FREDERICK GRATTON, of Stamford, Conn.—Commissioned an Assistant Surgeon in the Navy, June 22, 1891.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

ORIGINAL ARTICLES.

THE USE OF MORPHINE FOR THE RELIEF OF CERTAIN URÆMIC SYMPTOMS.[1]

BY W. H. WASHBURN, M.D.,
OF MILWAUKEE, WIS.

THE purpose of this paper is to show that there are certain uræmic symptoms, convulsions, renal asthma, and severe cephalalgia, for the relief of which morphine is specially indicated. This conclusion I shall attempt to reach by the only two lines of argument that can be pursued, that is, both by the deductive and inductive methods.

In what is to follow I do not wish it to be understood that I attribute to morphine, used under these circumstances, a curative influence; my only claim being that it relieves distressing symptoms, without adding to the dangers under which the patient already labors, and thus gives the physician an opportunity to resort to other well-known methods of treatment, namely: (1) To reduce the supply of poisonous substances in the blood by regulating the diet, by bowel disinfection, and by attention to the functions of the liver; (2) the removal of uræmic poisons by venesection, purgation, or diaphoresis; (3) their oxidation by the use of oxygen or active exercise; (4) the relief of particular symptoms or antagonizing the poisons. The subject-matter of this paper, therefore, pertains only to the fourth indication.

Headache, drowsiness, coma, dyspnœa, vomiting, diarrhœa, disturbances of sight and hearing, muscular twitchings and convulsions, are the symptoms which appear, in varying combinations, in that condition to which the term uræmia is applied. These symptoms are the result of the retention in the blood of certain excrementitious substances which the kidneys, in the course of Bright's disease, acute or chronic, have been unable to eliminate. They are an expression of the deleterious effects of these poisonous substances upon the brain and nervous system. That these symptoms are not the result of the retention in the blood of urea has long been known, although under that supposition the term uræmia was applied to them.

The symptoms being thus various and diverse, it seems reasonable to conclude, and experiment has proved, that they are not the effect of any one or two toxic substances, although it is not possible to determine positively what particular symptom is caused by a given excrementitious substance. Experiments with a view to the elucidation of these problems, though surrounded by many difficulties, have been entered upon by Bernard, Traube, Frerichs, Feltz, Ritter, Lepine, Zalesky, McMunn, and many others. It has been shown, for example, that when the amount of urea in the blood is increased a diuretic effect is produced upon the kidneys; that when urea is injected into the blood of animals in any reasonable amount it is rapidly eliminated by the kidneys, and causes no uræmic symptoms (McMunn, *Clin. Chem. Urine*, p. 38). A guinea-pig died in two hours and seventeen minutes after receiving a subcutaneous injection of ten grammes of urea; a second died in twenty-one minutes after an injection of 128 cubic centimetres of urine, containing ten grammes of urea—thus showing that, although urea in large amounts is undoubtedly poisonous, the other constituents of the urine are much more so (Dr. F. P. Henry, THE MEDICAL NEWS, vol. liv., 1889, p. 477). *Creatinin* injected into the blood of dogs caused feebleness and muscular contractions. Ligating the ureters in snakes and birds, in both of which urea is excreted as uric acid, was followed by coma (McMunn, *op. cit.*), hence the theory that coma is probably due to the presence of an acid in the blood. That the potassium salts share in the production of the phenomena of uræmia has been experimentally shown (*Medical Record*, vol. xxxv., 1889, p. 493). Bouchard has demonstrated that the coloring matters of the urine give rise to at least some of the symptoms of uræmia (*Lancet*, vol. ii., 1885, p. 161). Cuffer thought uræmic symptoms were caused by the destruction of red blood-cells. Hughlings-Jackson attributed some of these symptoms to spasm of the cerebral vessels. In addition to the substances already mentioned there are leucin, tyrosin, creatin, and other nitrogenized extractives, besides ptomaines and leucomaines, which must be regarded as adding to the sum-total of the phenomena of uræmia.

In a given case the symptoms observed will, therefore, vary as the proportions of these different toxic substances in the blood vary. In one case vomiting and diarrhœa may be the prominent symptoms;

[1] Read before the Milwaukee Medical Society, April 14, 1891.

in another headache, asthmatic attacks, or convulsions; in still another, delirium, tinnitus aurium, hemiplegia, coma. The varying effects of uræmic poisons may further be observed in a study of the condition of the pupils. In uræmic dyspnœa the pupil is usually dilated, though when the condition deepens to one of apnœa the pupil becomes contracted. Dickinson (*Treatise on Albuminuria*) reports several cases of uræmic coma occurring in the course of granular degeneration of the kidneys, unaccompanied by muscular twitchings or convulsions, in which the pupils were contracted, or in which it is noted that one pupil was contracted. Roberts (*Urinary and Renal Diseases*) reports numerous cases of uræmia from obstructive suppression of the urine, in which the pupils were strongly contracted—great restlessness, insomnia, or vomiting and diarrhœa being the most prominent symptoms. Grainger Stewart (*Lectures on Albuminuria*) reports a case of uræmia resulting from granular degeneration of the kidneys, in which the pupils were contracted while the patient was delirious, drowsy, and breathing with difficulty. During the convulsions this patient had, the pupils were widely dilated; as the convulsive movements and twitchings subsided, the pupils again contracted. During the earlier stages of chronic interstitial nephritis the pulse is full and hard, and the blood-pressure high. It is during this period that the urine is increased in quantity, and its specific gravity is low. Later in the history of the disease the heart's action becomes impaired, blood-pressure is lowered, the urine decreases in quantity, and dropsical effusions and uræmic symptoms appear. The condition of the pupil bears a tolerably definite relation to the blood-pressure, so that when the pressure is high and the amount of urine large, the pupil is contracted or natural; when the pressure is low and the urine less abundant, the pupil becomes dilated (Kirk, *Lancet*, vol. ii., 1886, p. 1153, also Mickle, *ibid.*, 1154).

In uræmic poisoning, when convulsions, cephalalgia, or renal asthma constitute the predominant symptoms, we have, with the first two, spasm of the arterioles of the cerebral cortex; in the last, spasm of the pulmonary arterioles (Dr. Stephen Mackenzie, *Lancet*, vol. ii., 1889, p. 263), and, at the same time, rapid and ordinarily feeble pulse, low blood-pressure, dilated pupils, and diminished secretion of urine. In the case of renal asthma there is, as stated, spasm of the pulmonary arterioles; as a result of the consequent dyspnœa there is imperfect aëration of the blood; the abnormal blood, acting upon the vasomotor centres, and also upon the bloodvessels themselves (Foster's *Physiology*, Part II.), causes general arterial constriction and constriction of the renal vessels (as is shown by the actual reduction in the size of the kidney), and hence diminution in the urinary flow. The quantity of urine secreted in a given time is directly dependent upon the blood-pressure (McMunn, *op. cit.*, 13); and hence the amount of urine will be increased by any condition that increases the general blood-pressure, unless there is at the same time constriction of the renal arteries. The objects then to be accomplished under such conditions as these are: To relax the spasm of the arterioles of the lung and of the cerebral cortex; to diminish nervous sensibility, both sensory and motor; to increase the general blood-pressure while relieving the constriction of the vessels in the kidneys, thus increasing the urinary secretion. Have we a drug in the materia medica the exhibition of which can reasonably be expected to fulfil these various indications? I think we have.

In considering the physiological effects of morphine, in full therapeutic doses, it will only be necessary to inquire into its effects upon the nervous and circulatory systems and upon the action of the kidneys. Its effects upon the nervous system are to lessen sensibility, both sensory and motor, thus relieving pain and relaxing spasm. Acting upon the circulatory system it at first produces temporary acceleration of the pulse-rate, soon followed by slowing and increased fulness and force as a result of the action of the drug upon the inhibitory cardiac nerves. The blood-pressure is thus increased. There is no unanimity of opinion as to its action upon the kidneys, some authors affirming that it increases the flow of urine, and others that it diminishes the flow. At all events, it is perfectly clear that it sometimes does increase the amount of urine, and that it must do so by its action upon the blood-pressure and by the relief of local arterial constriction. When retention of urine follows the use of morphine it results from the blunted sensibility of the bladder. Morphine increases the excretion of urea in man (Sfubini, quoted by H. C. Wood, *Therapeutics*, 7th ed.), and contracts the pupil.

We thus have *à priori* the clearest and strongest possible grounds for administering morphine for the relief of the conditions named—convulsions, renal asthma, cephalalgia. The indications sought to be fulfilled—relief of spasm, alleviation of pain, increase of blood-pressure, and hence increase in amount of urine—are exactly met by the known physiological effects of the drug. At this time, however, we are fortunately not limited to *à priori* reasons for anticipating favorable results from the use of this drug; there are abundant facts *à posteriori* to substantiate the validity of the deduction that, the conditions indicated being present, neither in acute nor in chronic uræmic intoxication will morphine add to the dangers already existing, but that it will uniformly produce happy results.

The history of the use of morphine in such cases reaches back to as early as 1868, when Loomis first used the drug hypodermatically in a case of acute uræmia. Dr. Bontecou (*New York Medical Journal*, vol. xi. p. 176), in 1870, gave by this method three-fourths of a grain of morphine to a woman who had just had a puerperal convulsion; in about one hour she had another eclamptic seizure and became comatose; nevertheless, another injection of one-half grain of morphine was given. There were no more convulsions for six days, when a severe paroxysm occurred; the woman received at once one grain of morphine hypodermatically, delivery was effected, and recovery took place. R. E. Johnson (*Lancet*, vol. ii., 1889, p. 14) has reported a case of puerperal eclampsia, in a young primipara, in which the urine was scanty and contained albumin. The case was treated with large doses of tincture of opium for two or three days; the sensibility of the bladder was so blunted that retention of urine resulted, but by means of a catheter about the normal amount of urine was withdrawn. Profuse diaphoresis followed the use of the opium, the convulsions ceased, and the patient made a good recovery. Alfred Grace (*Brit. Med. Jour.*, vol. i., 1889, p. 588) has reported two cases of puerperal eclampsia treated by large doses of morphine administered hypodermatically, one case receiving one grain as the first dose: both cases recovered. Obstetric literature has for some years past been replete with favorable reports of similar experiences from both sides of the Atlantic. In fact, so uniform have these results been that it may be fairly stated that Dr. Fry (*Am. Journ. of Obst.*, vol. xxi., 1888, p. 536) gave expression to the dominant opinion when he said: "In the treatment of puerperal eclampsia, we have as palliatives chloroform, potassium bromide, chloral hydrate, and morphine. Of these, morphine administered hypodermatically is by far the most reliable." That the convulsions of puerperal women are, in most cases, if not in all, of uræmic origin, is generally admitted, so that the treatment of puerperal eclampsia, so far as palliative measures are concerned, resolves itself into the question of the treatment of uræmia.

The field of usefulness of morphine in uræmia, as stated by Purdy (*Bright's Disease and Kidney Affections*, p. 84), is not confined to convulsive seizures. Morphine is not less serviceable in the relief of renal asthma and severe headache occurring in the course of chronic Bright's disease. About a year ago I had under observation for several weeks a case of chronic interstitial nephritis. There had been one slight convulsive seizure, but the symptom which rendered the patient's life intolerable was excessively severe and continuous headache. Ordinary means afforded no relief, and finally morphine was given and with the most satisfactory result. My notes of the case show that the pupils were dilated, and that, as a rule, the pulse was slow and weak. For the thirty days during which morphine was administered the average daily amount of urine passed was 41 ounces, whereas 32 ounces had been the daily average for some days previously. As to the elimination of urea during the thirty days of morphine treatment, the amount varied from 304 to 472 grains per day, which, considering the non-nitrogenized diet of the patient, was a fair amount. Therefore, it cannot be said that in this case the opiate reduced the amount either of urine or of urea.

Dr. Stephen Mackenzie (*Lancet*, vol. ii, 1889, p. 209) reports a case of chronic uræmia, in which the most urgent symptoms were insomnia, headache, and dyspnœa; after exhausting other resources, he prescribed morphine with the most gratifying results and complete relief of all distressing symptoms. In this case, it is noted that before morphine was prescribed the patient was daily passing 4 ounces of urine of a specific gravity of 1010; the heart's action was irregular. Subsequently, while the patient was under the morphine treatment, the daily amount of urine was from 28 to 32 ounces, with a specific gravity of 1008, and the heart's action became regular and steady. Carter (*Brit. Med. Journ.*, vol. i., 1889, p. 943) treated a boy, twelve years old, who was suffering from uræmic convulsions, with hypodermatic injections of morphine, which arrested the convulsions, and the boy recovered. He has treated many other cases in a similar manner, and with equally happy results. Carter remarks that a contracted condition of the pupils is a contra-indication to the use of morphine. Ralfe also records cases of uræmic dyspnœa completely relieved by the use of morphine, with no untoward symptoms following.

The foregoing cases are selected from among very many of the same kind, which might be easily drawn upon to furnish the inductive proof of the deductive conclusion arrived at—that morphine, administered in the manner indicated, *does* relieve spasm and mitigate suffering, and does *not* interfere with the action of the kidneys. It is true that cases of nephritis have been reported in which comparatively small doses of opium or Dover's powder have been closely followed by coma and death, but in view of the facts on record and the natural history of the disease, coma and death often following very closely upon convulsions in which no opiate was used (Roberts reports a most instructive case of this kind), and when the disease was *not* far advanced, it is *not* a legitimate conclusion that the fatal issue was caused or hastened by the drug.

In therapeutics there can be but two guiding principles: the empirical, or that based upon the

results of experience, and the scientific or rational. If the facts stated in this paper are not entirely chimerical and imaginary, we are warranted by both these principles in the use of morphine for the relief of the uræmic symptoms dwelt upon, namely: convulsions, dyspnœa, or renal asthma, and cephalalgia, all accompanied by dilated pupils. Opinions and practices handed down to us from the past are, however, often clung to with great tenacity, particularly when indorsed by eminent men. The great University of Salamanca questioned the value of Newton's discovery one hundred years after the publication of the *Principia*. Innovations are looked upon with dread. In ancient Egypt, the law defined the mode of treatment to be pursued in every disease, and if a physician deviated from the prescribed methods, and his patient died, his life paid the forfeit. In the last half of the last century (Buckle, *Hist. Civilization*, vol. ii. p. 75) some bold innovator suggested that possibly the great prevalence of disease in Madrid might be due to the filth which for centuries had been accumulating in the streets and alleys of the city. A meeting of medical men was held to discuss the question and after mature deliberation they concluded that it was best to let the filth remain; that their fathers were wise men, and had not disturbed it, probably having good reasons for not doing so; that in all probability the gases arising from the decaying animal and vegetable matter rendered the air heavier, thus rather tending to lessen the prevalence of disease; and, moreover, cleaning the streets would only be an experiment, and no one could see the issue of new experiments.

Although morphine has been used in cases of acute uræmia for more than twenty years, and in cases of chronic uræmia for several years, and with results as uniformly happy as attend the use of any other drug in any other condition, and although the indications to be fulfilled call for the administration of a drug producing physiological effects identical with those resulting from the use of morphine, there are still those in the profession who are oppressed by the unsupported traditions of the past, and regard its use with apprehension.

803 Grand Avenue.

CHRONIC ENDOMETRITIS.[1]

By J. S. CAIN, M.D.,
of Nashville, Tenn.;
Professor of the Practice of Medicine and General Pathology in the Medical Department of the University of Tennessee.

Although the title of my paper would embrace the entire uterine canal, cervical as well as corporeal, I shall restrict what I have to say to the diseases of the body of the organ, only alluding to the pathology of the cervical portion proper when it becomes necessary to do so in treating of endometritis in general. The question as to the localization of the chronic form of endometritis is rendered more prominent than that of the acute form, on account of the conflicting opinions entertained by distinguished authors and teachers. None, I believe, question the frequent occurrence of chronic cervical endometritis, but Drs. Emmet, Bennett and other distinguished authorities almost absolutely ignore the existence of chronic corporeal endometritis as a special disease, and consequently, except for the relief of hemorrhages and to meet temporary emergencies, discountenance all intra-uterine medication, relying entirely upon treatment directed to the uterine os and vault of the vagina; but the great preponderance of medical authority is adverse to the opinions entertained by these gentlemen, and with this class I am entirely in accord. Dr. Arran says: "Internal chronic metritis is more frequent in the cavity of the body than in the cavity of the neck of the womb, notwithstanding all that has been said to the contrary," and this opinion is concurred in by Dr. West and others.

Chronic endometritis and the conditions necessarily allied therewith are the most common as well as the most important diseases with which the gynecologist has to deal. Chronic endometritis is often a sequela to the acute form of the disease and is a result of repeated acute attacks. It matters not how or from what source the outbreaks originate, whether from catarrhal, specific, traumatic or internal constitutional causes, they often (but not always) constitute the starting-point from which not only the endometrium, but also all the uterine and peri-uterine structures become involved. I will venture the assertion that, while the change in structure and function of the lining membrane of the uterus often seems to be the most prominent condition and that which demands first and most careful attention, this tissue is probably never chronically diseased without a corresponding involvement of all the uterine structures. The starting-point of these troubles has of late years provoked more or less discussion and revealed differences of opinion among scientific investigators. Doléris and many others believe that acute endometritis is necessarily the initial lesion in every parenchymatous inflammation of the uterus or of the peri-uterine tissues, and that when acute lesions of these structures disappear chronic endometritis remains. Modern pathology strongly inclines to the belief that inflammatory affections of peri-uterine structures, most notably the tubes, are often secondary to involvement of the vaginal and uterine mucous membrane—and gonor-

[1] Read before the Tennessee State Medical Society, April 14, 1891.

rhœa comes in for no small share of the blame. That chronic endometritis does often originate from acute invasions of the uterine mucous membrane there can be no question. These leave their effects upon the endometrium in inflammatory thickening and hyperplasia and in adenomatous degeneration of the abundant glandular structures, thereby unfitting the organ for the normal performance of menstruation and all other functions belonging to it, and resulting in hemorrhages and leucorrhœa, as well as numerous other morbid conditions to be described. Ziegler says that "hyperplasia of the uterine mucous membrane is very common," and that it causes "changes in structure and appearance, with polypoid and fungoid excrescences and enlarged and hypertrophied utricular glands, which when pared off by the surgeon present the appearance of adenomata." This condition of the uterine mucosa, by interfering with the circulation in the organ, probably always produces more or less hyperplasia in the uterine muscular and connective tissues. Dr. Stimson, an able writer and accurate thinker, emphasizes the importance and the far-reaching effects of this pathological obstruction in the following language: "The obstruction of the return current in the uterine mucous membrane, and the resistance of the diseased membrane often result in hæmatocele."

Probably the most common form in which we encounter the condition of the lining membrane of the uterus known as chronic inflammation, and which has all of the pathological characteristics of that disease, comes on without any appreciable antecedents. I have asserted with authority that uterine hyperplasia is often a concomitant and sequence of chronic endometritis. Now, this order may be reversed, and I may assert that endometritis is frequently dependent upon and produced by uterine subinvolution, or the condition denominated by Dr. Thomas areolar hyperplasia, or it may grow out of or develop from diseases located in other pelvic organs, such ovaritis, in which event the chronic form of endometritis comes on and develops to its pathological acme, without passing through any appreciable acute stage.

Lawson Tait, in his recent excellent work on *Diseases of Females*, asserts that "chronic endometritis may result from the acute process, but it is infinitely more frequently associated with the chronic metritis resulting from subinvolution. It is sometimes met with in young, unmarried women, associated with chronic ovaritis; it is then a fertile source of bad health, and when they come to be married, of sterility." Thus areolar hyperplasia or sclerosis of uterine tissue, by interfering with the circulation in and the nutrition of the lining membrane of the organ, brings about a state of degeneration of tissue clinically similar to, if not pathologically identical with, chronic endometritis. The thickening of tissue, the tendency to fungoid degeneration, and adenomatous conditions of the glandular structure, all interfere with menstruation and call for similar treatment. Displacements and malpositions of the uterus, by obstructing and interfering with the normal circulation, often result in the same condition and may be considered as common causes of chronic endometritis. This view of displacements interfering with uterine circulation is, however, disputed by Dr. John Williams, of London, who seems to have given some study to the matter, and who maintains that changes in the position of the organ, owing to the arrangement of the blood-supply do not at all interfere with its circulation. Many others entertain similar opinions and pay but little attention to the restoration of the uterus to its normal position in the pelvis as one of the steps necessary to the relief of its chronic inflammation. In this matter I must, however, concur with Dr. Stimson, who believes "the uterus to be an organ of very great variations in vascularity," and conclude that changes in position consequent upon hyperæmia, enlargement of the organ from whatsoever cause, relaxation of ligamentous, muscular and connective-tissue supports, all tend to throw it out of its normal anatomical relation, to interfere with the circulation and nutrition, and to develop the diseased condition of the endometrium as described.

After this brief review of the etiology and pathology of the disease under discussion, having determined its presence by the well-known symptoms and signs, having made a careful differentiation between the corporeal and cervical forms, and having excluded the possibility of malignancy (probably one of the most difficult problems which the general practitioner or even the gynecologist is called upon to solve), we come to the subject of treatment. I would formulate the indications for treatment as follows: Remove, as far as possible, all constitutional, predisposing and disease-fostering causes that may exist in the patient or in her environments; restore, as far as possible, the uterus to its normal position in the pelvis, thereby correcting the cause of obstructed circulation, and deplete the engorged tissues by all means at command; remove adenoid and fungoid vegetations from the cavity of the uterus, if they exist, and endeavor by local, therapeutic measures to restore the endometrium to a condition as nearly normal as possible. The indications are plain enough, but in carrying out the treatment to a successful result is encountered one of the most difficult problems in medicine. I will venture the assertion that the condition of the uterus, in which some or all of the pathological changes noted exist, from chronic

subinvolution to fungoid vegetations of the mucous membrane, with the corresponding train of symptoms, may be palliated by treatment, but it is not within the province of remedial measures to restore the organ to perfect normal function.

To accomplish the first indication in treatment a most rigid investigation should be instituted as to the existence of constitutional causes. Dyscrasiæ, if detected, should be combated with hæmatic reconstructives; struma, with sulphide of calcium, the iodides, cod-liver oil, etc.; arthritis, with iodine, lithates and salicylates. If anæmia or toxæmia exist to such a degree as to interfere with normal repair, tonics and ferruginous reconstructives are to be administered. If digestion and assimilation appear to be defective, an appropriate and nutritious diet, artificial digestants, tonics and eliminants, nearly always embracing arsenic in some form, are indicated. This line of medication, with a due regard for the sanitary environment of the patient, constitutes our general therapeutic resources.

To meet the next indication a great variety of measures has been resorted to. Pessaries and supporters of every conceivable design, abdominal, vaginal and intra-uterine, have been used; and while pessaries, judiciously selected and intelligently employed, after all active symptoms have disappeared and laxity of fibre and defective support of the organ remain, sometimes give great relief, I think it may be safely said that during the active existence of the disease all pessaries are worse than useless. The idea of employing some soft, elastic, light material as a support for the uterus, which, while it serves the purpose of holding the organ *in situ*, might at the same time be used as a means of accomplishing the local application of medicaments to the vagina, os and cervix, was early conceived. Soft sponge was thus employed. This article soon developed objectionable features, in consequence of its irritation to the tissues, as well as its tendency to become offensive and harbor germs and poisons. The support of the womb by a tamponade of cleaned and medicated cotton next came into use and has remained popular with the profession for many years. Drs. Mundé, Goodell and others have used this plan of treatment with great satisfaction when properly applied—so as to exert pressure upon the engorged cervix while it supports the decadent and always heavy womb. This mode of treatment evidently accomplishes good results; besides, it may be made to subserve a most valuable purpose by maintaining a constant supply of glycerin, either medicated or anhydrous, in contact with the region in which local depletion is to be accomplished. The tendency of cotton, however well prepared, to pack and become inelastic suggested the employment of some agent free from these objections; hence the introduction of jute and wool, which have been so popular of late, especially for dry treatment. The hard and irritating qualities of these textiles, with their poor absorbing properties, have been thought objectionable, and a compromise has been effected by combining cotton with the other articles, a combination which just now probably constitutes the best vehicle before the profession for vaginal tamponade.

In cases in which decided chronicity exists, with sclerosis of uterine tissue, constitutional measures will doubtless prove of but little avail in the treatment, but when there yet lingers an acute condition, evidenced by tenderness on pressure and inflammatory engorgement, much good may be accomplished by constitutional and general means. Depletion of the pelvic organs by saline purgatives, systematically employed, when the blood supply and other conditions warrant it, should not be neglected. Scarification, leeching, bleeding the os by puncturing and depletion by the use of glycerin—each has its advocates, and doubtless each possesses some merit. Iodine, in the form of the tincture, applied to the vault of the vagina is a favorite remedy with many.

Internal therapeutic remedies are almost universally employed in this class of cases. Ergot, for its supposed influence in cutting off and lessening the blood-supply to the uterus, is unquestionably a deservedly popular remedy. The iodides are extensively used in this form of chronic endometritis attendant upon uterine subinvolution, with subacute or lingering acute characteristics. Bromide of potassium is regarded by many as almost specific. Mr. Lawson Tait regards the benefit derived from this salt as due alone to the potassium, and believes that other salts of potassium besides the bromide are equally efficacious, and in some way not explicable prove valuable remedies in these cases. He is particularly partial to a combination of the fluid extract of ergot and chlorate of potassium in what I would consider extremely minute doses. I have often with satisfactory results employed the ergot with bromide of potassium, but feel inclined to attribute the results to the ergot rather than to the combination.

Some practitioners reject the whole system of local depletion, except by Dr. Emmet's method of long-continued vaginal irrigation with hot water, followed or alternated with glycerin tamponades; while I have fallen into the popular use of hot-water irrigation in nearly every diseased condition of the pelvic organs, as taught by Dr. Emmet, and believe that the treatment, when properly administered, has a field of vast usefulness, especially when the disease is located in the cervix or in the pelvic tissues below the cervix. Still I am convinced that

the treatment has become very much of a hobby with the profession, and is often made to do duty when it cannot possibly be of the least benefit. Granting all the therapeutic effects claimed for the treatment, after long investigation and study I doubt if it has any effect whatever in depleting an engorged uterus or in lessening the blood-supply to the body of the organ; except for purposes of cleanliness and as an auxiliary to other treatment, it might well be dispensed with in all diseases situated above the internal os.

Chronic endometritis, in its legitimate and almost universal course, implies a degraded condition of the tissue, characterized by a fungoid and adenomatous degeneration, with a tendency to hemorrhage and mucous and muco-purulent discharges; probably no department of my subject has provoked such wide diversity of opinion as has the treatment of this peculiar condition. Except for the relief of the fearful hemorrhages which frequently attend it, many of the best practitioners are inclined to let the interior of the uterus severely alone and not to invade it with either instruments or other therapeutic measures. While the great majority of practitioners and gynecologists strike at this symptom of the disease as the all-important matter to be combated, nearly every author and teacher in this department has his own peculiar views upon the subject. Dr. Emmet is opposed to the practice of making applications to the interior of the uterus. He claims that the discharges from the lining membrane are in general the result of hyperæmia, which is secondary to pathological or mechanical changes outside of the uterus, and that the rational treatment consists in measures directed to the cause and not to the consequence; and, therefore, except for the relief of hemorrhage resulting from vegetation, the relies upon vaginal medication applied to the os. Diametrically opposed to these views are those entertained by Doléris and a host of others, who agree with him in the main, but who differ somewhat in the methods of accomplishing the objects sought. He maintains that the lesion is in the endometrium, and that therefore the treatment must be local and directed to that particular tissue. His practice is to thoroughly dilate the cervix with aseptic tents when necessary, and then to curette the uterine cavity, swab it out with a 1:4 solution of carbolic acid and wash it out with a 1:2000 sublimate solution. Dr. Mundé also favors intra-uterine medication; he protests against the growing tendency to abandon medication applied above the internal os and believes that we herein possess a means of treatment for which there is as yet no adequate substitute.

The use of strong caustics and escharotics is favored by many. Nitric, chromic and carbolic acids, iodine and desiccated sulphate of zinc, all have their advocates; and if we can rely upon the reported cases of Rheinstädter, as affirmed by Bröso, Fränkel and Dumontpallier, intra-uterine cauterization with chloride of zinc has accomplished marvellously good results in his hands. During the last ten years he has employed the treatment in nine hundred and seventy cases. He applies the zinc twice a week; six weeks are sufficient to bring about a cure. Ergot, hot-water douches and glycerin tampons, with the zinc cauterization, will within three months reduce the largest and hardest uterus to normal conditions, both in size and secretion. Others assume a middle and more conservative ground in the treatment of chronic endometritis. Dr. Engelmann, although not entirely disapproving of intra-uterine medication, believes that its sphere of applicability is greatly narrowed and that rarely should any but the milder agents be used. Vaginal or indirect medication by means of dry tampons of cotton, wool or jute, impregnated with various agents or serving as carriers of powders, is, in his opinion, in the vast proportion of cases sufficient, and withal without the possibility of the ill-effects that may follow intra-uterine applications.

Another treatment, of late coming into vogue, in which I have considerable confidence, especially in cases of long standing and decided chronicity, is known as Vulliet's method, practised by Landau, Chrobak and many others. It consists in thoroughly dilating the cervix and packing the cavity of the uterus with gauze or wicking, medicated with iodoform or other agent. The application must be made with the patient under the influence of an anæsthetic; the packing should be removed in twenty-four hours.

Dr. Alexander Dunn, in *The British Medical Journal*, has recently reported wonderful success in the treatment of chronic endometritis with boric acid. He says that, "having obtained the most decided benefits in the treatment of vaginal leucorrhœa and erosion of the os and cervix, both acute and chronic, from vaginal applications of boric acid," he "not long since designed a convenient form of insufflation for the purpose." Thinking he could go a step further and apply the acid to the endometrium itself, he found that by means of a slightly curved vulcanite tube, somewhat larger than a No. 12 catheter, with a tightly-fitting rod or piston of the same material, the application could be safely made. The insufflator or tube is tightly filled for about two inches from its extremity by plunging the end into a vial or other vessel containing the acid and withdrawing the piston. When so filled the tube is introduced through the patulous cervix into the uterine cavity, which has previously been cleaned with a wire curette. "The piston is

pushed home and a stick of compressed boric acid is deposited in the uterus. By this simple means I have succeeded in curing quite a number of cases of this troublesome and intractable complaint, some of which had previously, both in my own practice and in that of others, resisted the usual routine caustic treatment. Judging by my own experience I should say that if this treatment be adopted as described, the most chronic cases of endometritis should yield to a dozen such applications at most, at intervals of three or four days."

After a review of these somewhat conflicting views and plans of treatment—which, while they constitute but a fraction of the methods to be found in the books and journals of the period, probably embrace the leading and most prominent ideas upon the subject—and having referred to the sure-cure, never-failing, well-authenticated plans of treatment practised by distinguished gentlemen who pursue a single and well-defined course of treatment in all cases with the single result of cure—in which I will modestly say I have but little confidence, I will proceed to give the line of local treatment that I am, as a general rule, accustomed to practise in these cases. While the curette, as has been said, is a blind instrument and capable in careless and incompetent hands of doing much mischief, yet for the removal of fungoid vegetations and adenoid degenerations from the endometrium it affords the surest, speediest and safest means as yet devised. I am accustomed to follow the curetting by an application of Churchill's tincture of iodine or diluted carbolic acid, and always precede the treatment by a careful washing out of the vagina and uterus with a solution of 1 : 1000 or 1 : 2000 corrosive sublimate, after the method of Dr. W. G. Wiley. In cases in which this treatment is not admissible, or in which it has failed to afford relief, my next reliance is in the electro-chemical action of negative galvanism in removing the vegetations, after the method of Apostoli. This is accomplished by introducing into the uterine cavity an electrode, insulated to near the point and connected with the negative pole of the battery, the other pole being connected with a large pad of moistened potter's clay, sponge or prepared cotton, placed over the abdomen. The time for the employment of galvanism should be from ten to fifteen minutes at each treatment, and the treatment should be repeated about twice a week. The strength of the current to be employed will largely depend upon the acuteness of the case and the susceptibility of the patient to electrical influence. The chronic cases always require the stronger currents. The dosage may be fixed at from ten to three hundred milliampères; the minimum is, in my judgment, too small to accomplish any results, and yet practitioners with much larger experience than mine have had to employ it. This line of treatment is free from many of the objections to other modes of treatment. It is cleanly, free from pain and exempt from danger. Unlike cauteries and escharotics, it can be limited in its influence and produces no deleterious effects upon the sound tissues; nor does it leave a raw and exposed surface, as does the curette, to absorb poisons and septic matters; while it removes the vegetations, it imparts renewed tone and vitality to the diseased organ.

DISEASES OF THE HIP-JOINT.[1]

BY ARTHUR J. GILLETTE, M.D.,
ORTHOPÆDIC SURGEON TO ST. LUKE'S HOSPITAL, VISITING ORTHOPÆDIC SURGEON TO THE UNIVERSITY DISPENSARY, ST. PAUL, MINN.

THE title of this paper, "Diseases of the Hip-joint," is used instead of "Hip-joint Disease," because the latter term is applied more generally to a tuberculous inflammation, although, with authorities, I am inclined to believe that tuberculous hip-joint disease always begins as a simple inflammation following trauma, and by inoculation subsequently becomes tuberculous. There are diseases of the hip-joint the origins of which, I am sure, are not due either to injury or to tubercle bacilli, but which are constitutional diseases with local manifestations.

I am prompted to choose this subject for two reasons:

First. At the onset, these cases always have the same clinical appearance as those of the more chronic, or of a true tuberculous nature, and in several instances my prognosis did not prove correct, although I am sure that my diagnosis was undoubtedly accurate as regards an inflammation of the hip-joint.

Second. On several occasions, when I gave a prognosis in cases of chronic hip-joint disease, the family physician informed me that, by rest in bed, and extension by weight-and-pulley, he had cured cases of hip-joint disease in a few weeks. Thus was strengthened my belief in an inflammation non-tuberculous in the beginning, but with subsequent inoculation—usually occurring before it is placed in the hands of the specialist, and hence running a chronic course, with effusions and rupture of the joint capsule. Dissection of the soft parts may follow by the effusion becoming purulent, because of the breaking down of the soft parts, or of infection following the opening. This emphasizes the most important feature in the treatment of hip-joint disease, viz., an early diagnosis—since I believe it is sometimes possible to check the progress of these cases before they become chronic or tuberculous.

[1] Read before the Inter-County Medical Society of Wisconsin, March 10, 1891.

The occurrence of peritostitis in the long bones, following scarlet fever, measles or typhoid fever, is not at all uncommon. Dr. Keen[1], of Philadelphia, has given a full account of all the bone-lesions following the continued fevers. He found 69 cases, of which 22 affected the head, 7 the trunk, 6 the upper and 42 the lower extremities. There were 37 cases following typhoid fever. As to the date of occurrence in 47 cases, 10 were within two weeks, 27 from three to six weeks, and 10 some months after the fever. Keen's explanation was that the earlier cases probably came from clot, and the later from enfeebled nutrition. He found that the periostitis arose spontaneously or as a result of slight injury.

V. P. Gibney[2] read an original article before the American Orthopædic Association, entitled "Typhoid Spine," in which the clinical aspect resembled very closely that of beginning Pott's disease. In this paper he reports cases of disease of the hip which bear a close resemblance to tuberculous hip-joint disease. One was that of a young lady, eighteen years old, convalescing from typho-malarial fever and suffering with acute pain in the hip. Any movement of the limb would excite cries of pain. She was not of an hysterical, but rather of a lymphatic temperament. Weight-and-pulley and a traction hip-splint afforded relief in less than a month. A few months afterward there was no lameness, pain, or reflex spasm, although, as compared with the other limb, there was some limit to the free range of motion. Dr. Gibney's conception of the pathology was a circum-articular lesion confined to the periosteum or ligaments. Another case was that of a boy aged thirteen. For four or five months after having had typhoid fever, while confined to his bed, he kept both limbs flexed on the abdomen, and during convalescence was unable to straighten them. He was poorly nourished, and quite unable to walk. The thighs were sharply flexed on the pelvis, the legs on the thighs, the heels touching the buttocks. Any attempt at motion of the right thigh caused reflex spasm.

At the meeting referred to all the members seemed to acquiesce in the views of the author, and many reported cases of joint-troubles occurring in their own practice, following acute severe fever, the exanthemata, etc.

There is still another constitutional affection that I believe accounts for many diseases of childhood, and which often manifets itself in the form of joint-disease. I refer to hereditary syphilis; and I would ask the general practitioners present: How many cases of acquired syphilis continue the treatment so long as you advise? Do they remain under your care after the initial sore is well? I have carefully questioned a number of fathers whose children I was treating for joint troubles, and have been somewhat surprised at the number who acknowledged that at some time previously to their marriage they had had suspicious sores. I am also aware that syphilis usually manifests itself by pemphigus of the hands and feet, various eruptions, a copper-colored discoloration of the skin, characteristic snuffles or coryza, stomatitis, laryngitis, etc., and that all these symptoms usually occur before the end of the first year; but there are well-authenticated cases of hereditary syphilis in which the disease did not make its appearance until the twentieth and twenty-fifth years.

Some time ago a patient, a child not quite two years old, was sent me from a neighboring town, exhibiting all the symptoms of double hip-joint disease, and with no history of an injury. The disease had existed in the left leg for some months longer than in the right. The parents gave me the following history: The child had always been remarkably healthy, well-developed and intelligent, never having had any eruptions, although the parents thought it had been troubled with "snuffles." The teeth appeared punctually, and the fontanelles closed early. About three months prior to my seeing the child the first symptoms exhibited were loss of sleep and night-cries. At times, if the left limb was handled a little roughly, the child would cry, but at other times this did not seem to produce the slightest uneasiness. From day to day it was observed that the child held the limb flexed and adducted; following this the right limb became tender, was soon flexed and adducted in the same manner, so that when I saw the child both limbs were adducted, both thighs were almost completely flexed upon the abdomen, and the legs flexed upon the thighs. In this position the child had been for a number of weeks, and in all my experience I have never, in any disease, witnessed a patient suffer such agony and excruciating pain. The slightest jar of the floor or bed would cause pain. When I saw the child, movement being so intolerable, the napkins had not been changed for a number of days. It was impossible to make an examination without etherization. Upon extension of the limbs there was the characteristic lordosis of the spine. After etherization this entirely disappeared. The left leg, in which the disease first manifested itself, was one quarter of an inch shorter than its fellow, although it appeared longer. This, of course, was due to the tilting of the pelvis. I applied a plaster cast to keep the joints quiet. A general practitioner, administering ether, called my attention to the gums and teeth, which had the

[1] Trans. of Amer. Orthopædic Assoc., vol. ii. "Typhoid Spine," by V. P. Gibney.

[2] Ibid., vol. ii.

exact appearance described by Hutchinson. The gums were of a highly congested, swollen and peculiar spongy appearance. The child had also a severe laryngitis. The immobility of the hips did not relieve the pain. After a few days I applied a weight-and-pulley, and the child was asleep before I left the hospital. The flexion was not overcome so rapidly as usual under this treatment, although the pain was almost completely relieved. I then began the administration of mercury, both internally and by inunction. From the very time that this was administered the child began to improve. In ten days or two weeks, every bit of pain about the hips had disappeared, the inflammatory condition of the mouth was completely relieved, and at the end of six weeks the little patient was apparently well. Six months have now passed, and the child has not had any local treatment for three months; the hips are freely movable in every direction, and the child, to all appearances, is in perfect health. This history, together with the fact that the father acknowledged he had suffered from a sore on his penis, proves conclusively that it was a syphilitic hip-joint, pure and simple.

Another case, I am sure you will agree with me, was undoubtedly syphilitic; it was referred to me by Dr. Sweeney, of St. Paul. The disease was of the right hip, in a boy aged seven years. There was apparent lengthening, but actual shortening; there was atrophy of the calf and thigh, but only slight tenderness; the leg was abducted and slightly flexed. The mother gave a history of the boy having had a similar attack four years previously. At that time the joint was very painful, and was put in a plaster cast; following this a peculiar eruption appeared, which puzzled the attending physician. A consultation was called and medicine given that caused the disappearance of the eruption, the symptoms about the joint immediately clearing up, and the child up to the present time seeming perfectly healthy. I applied the long traction-splint, and the mother, without consulting the family physician or myself, left for the country. I did not see the child again for three months, when I was called, and found the child, of course, in a very much worse condition than when I first saw it. The thigh was flexed, the joint exceedingly tender, and there was swelling all about the hip. I had, in fact, a typical picture of a tuberculous joint. I reapplied adhesive plaster and a splint, and advised rest in bed. I continued this treatment for about ten days, with but very little or no improvement. The mother called my attention to a peculiar eruption, which, she said, had appeared some time before, mostly on the upper part of the child's body. It was of a dull brownish-red color, with an ulcerated top, and varying in size from a pea to a nickel. At my request Dr. Sweeney was called, and he immediately placed the child under anti-syphilitic treatment. The child's general condition immediately improved, the aggravated symptoms about the joint disappearing as if by magic. I have since learned that from the habits of the mother she would be a very fortunate woman indeed if she had not at some time been infected with syphilis. The father was also immoral. The child is still wearing the brace, and I fear has now a tuberculous hip, although I believe the origin of the disease was due to syphilis. Without doubt, syphilis is a distinct causative factor of rickets, and it is clearly demonstrated that among children affected with hereditary syphilis tuberculosis is rife.[1]

A CASE OF PICROTOXIN-POISONING; WITH REMARKS.[2]

BY EDWIN B. SHAW, M.D.,
OF OSAGE CITY, KANSAS.

ON account of the infrequent use to which cocculus Indicus and its active principle, picrotoxin, are put, the intelligence of this Society will not be impugned by assuming that all its members are not familiar with the drug. A careful search has resulted in finding but five reported cases of picrotoxin-poisoning, two of which are open to doubt, so that the one about to be presented will be the sixth case on record.

Sometime during the month of October, 1890, by the courtesy of Dr. John W. Elston, then coroner of Jackson County, Missouri, I was permitted to witness a post-mortem examination in the case of a man dead after taking a concentrated tincture of cocculus Indicus.

A. H. N., fifty-one years old, a native of Germany, had been in poor health for ten years. About five years ago, when suffering from bronchial catarrh, he purchased, as he supposed, some wild cherries, which he requested a druggist to put in a half-pint flask, to be filled with brandy. Of this he, with two other members of the family, took teaspoonful doses at irregular intervals, without experiencing any untoward effects. The flask was then put away, and remained undisturbed and forgotten until about two weeks prior to the time of the man's death. At that time he took the flask, containing the dry berries, which he still supposed to be wild cherries, and had it filled with whiskey. Of this tincture he had been taking small doses for upward of a week. One morning, at about 10 o'clock, he took a considerable quantity from the flask, afterward complaining of feeling dizzy and sick at stomach. He excited vomiting by tickling the fauces, and expressed himself as feeling relieved, but in a few moments fell to the floor in a convulsion. Convulsions of a tonic

[1] Annual of Universal Medical Sciences, vol. i., 1890, No. 29.

[2] Read before the Eastern Kansas District Medical Society, at Topeka, Kansas, April 14, 1891.

and clonic character followed in quick succession, till death closed the scene. During the convulsive stage unconsciousness was complete. A period of thirty minutes elapsed from the time of taking the tincture till death ensued.

The post-mortem examination was made at 8 P.M. of the same day. Rigor mortis was marked. The body was excessively adipose. The abdominal walls were two and one-half inches thick. The lungs were healthy. The right was adherent throughout the chest. The heart was contracted in systole and empty, and perfectly healthy. The liver was fatty and enlarged. The spleen was flabby and friable, and normal in size. The kidneys were fatty and enlarged. The stomach was excessively dilated and empty; the mucous membrane was congested in spots. Unfortunately the brain and spinal cord were not examined.

To the credit of the pharmacists of Kansas City, be it said that the berries were sold by a speculator who had possession of and conducted the drug-store temporarily. One at all familiar with the appearance of the wild cherry and the fishberry could scarcely mistake the one for the other.

Dr. W. B. Thompson, of New York, has reported death, preceded by violent tetanic spasms, in a child six years old, following the application of a strong tincture of the fruit to the scalp. A case of fatal poisoning by cocculus Indicus is reported by Dr. Sozinsky (The Medical News, November 3, 1883); another by Prof. Mitchell (*Therapeutics*, Philadelphia, 1850).

Blythe, in his work on *Poisons: Their Effects and Detection*, reports two cases of poisoning by picrotoxin. "In 1829 several men suffered after drinking rum impregnated with cocculus Indicus; one died, the rest recovered. In the second case a boy, aged twelve, swallowed some of a mixture used for poisoning fish, the active ingredient of which was cocculus Indicus; in a few minutes he experienced a sensation of burning in the mouth, with pains in the œsophagus and stomach, frequent vomiting and diarrhœa. A violent attack of gastro-enteritis supervened, with fever and delirium. Death took place on the nineteenth day."

The two cases recorded by Blythe are certainly not clearly established examples of picrotoxin-poisoning. In fact, the boy in the second case presented few of the symptoms of picrotoxin-poisoning. This leaves but three fatal cases, excluding the case just reported, that are indisputable cases of picrotoxin-poisoning.

Although of not much practical importance, yet a brief study of the natural history, physiological action, toxic effects and therapeutical applications of cocculus Indicus, with a report of the changes found post-mortem in fatal cases of poisoning, will not be entirely without interest.

Cocculus Indicus is a native of the Malabar Coast and of Eastern insular and continental India. "As found in the shops, cocculus Indicus is a roundish berry, somewhat kidney-shaped, about as large as a pea, having a thin, dry, blackish, wrinkled exterior coat, within which is a ligneous, bivalvular shell enclosing a whitish, oily, very bitter kernel. It is without smell, but has an intensely and permanently bitter taste. It bears some resemblance to the bayberry, but is not quite so large, and may be distinguished by the fact that in the cocculus Indicus the kernel never wholly fills the shell."

Picrotoxin, the only active principle that has been made use of in medicine, is poisonous. Given to dogs in doses of from five to ten grains, it produced death, preceded by violent tetanic spasms, which, according to Dr. R. M. Glover, are very similar in character to those produced by Flourens by section of the corpora quadrigemina and cerebellum, being attended with backward rotary movements and tetanic spasms. Dr. Crichton Browne, by carefully-made experiments, has shown chloral hydrate to be antagonistic to the action of picrotoxin; anæsthetics and all relaxing and motor-depressing agents are antagonistic to its convulsive action. The action of strychnine is very similar, but differs somewhat in the character of the resultant spasm. In strychnine-poisoning the spasm is of a tetanic character, and the action of the cerebrum is not suspended till shortly before death. In picrotoxin-poisoning, a feeling of drowsiness precedes the convulsions and increases to profound coma with their continuance; the spasms are of a tonic and clonic character, principally, however, clonic. Recent experiments seem to show that the poison acts on the spasm- and vagus-centres in the medulla, and on Setschenow's inhibitory centre. Boeber finds that the electrical reactions of the nerve and muscle remain unchanged, proving that the effect of the poison is expended upon the centre and not upon the periphery. Bartholow, with several other authorities, states that the heart stops in diastole, the cavities full, the capillaries at the periphery empty; while the post-mortem examination in the case reported disclosed the opposite. Bartholow also affirms that picrotoxin is non-irritant to the gastric mucous membrane. This is quite improbable, because it is almost certain to produce nausea and vomiting. A portion of the poison remains in the blood, as is shown by the fact that flies are poisoned by drinking the blood in a fatal case.

Cocculus Indicus has long been used in India to stupefy fish, in order that they may be caught. It has been put to the same use in this country and in Europe. No cases have been reported in which unpleasant results attended eating fish caught by this means.

An ointment made of the powdered fruit has long

been used by the laity to destroy pediculi corporis, and it is claimed to be quite efficient in the treatment of tinea capitis. Being a cerebro-spinal stimulant, cocculus Indicus has been used in the treatment of a large number of diseases, but being possessed of so little real value, it is now never used except as a local application for the destruction of vermin.

[Picrotoxin has been used as a substitute for strychnine, in cases in which strychnine was indicated. In combination with belladonna it has, in the hands of some, acted happily in controlling the night-sweats of phthisis.—Editor of THE MEDICAL NEWS.]

MEDICO-LEGAL CASES.

BY HENRY A. RILEY, ESQ.,
OF NEW YORK.

Murder and Matrimony.—The recent execution of Eyraud in Paris for the murder of Gouffe, and the sentence of his accomplice, Gabrielle Bompard, to imprisonment for life, have served to keep this case in the public mind, and physicians have good reason to remember it for the claim made by the woman that she was hypnotized at the time of the murder, and the offer made on the trial to put her again under such influences. The morbid regard for women who commit murder is one of the curious circumstances connected with crime, and it is said that an appeal has been made for the pardon of Gabrielle Bompard by a man who promised to marry her if freed from prison.

The same offer was made in the well-known case in New York of Mrs. Druse, who, aided by her children, killed her husband, chopped him up, and boiled him. Governor Hill was asked by many persons to commute the sentence, and among others by a man whose matrimonial inclinations were not disturbed by the fact that the first husband had been killed in a remarkably deliberate and cold-blooded manner. The Governor, however, refused to be influenced by any so-called humane appeals or by the matrimonial offer mentioned above, and Mrs. Druse had to suffer the penalty of her crimes.

The New York Morgue.—The New York Medico-Legal Society has recommended the placing of the morgue in New York City on a scientific basis, under the direction of a competent physician. The great advantage to be derived from the change will be the increased facilities for the detection of crime. The morgue at present is managed in a haphazard sort of way, and many abuses are charged against it.

Weak Eyes in Children.—The last Legislature of New York passed a law as follows: "Should any midwife or nurse having charge of any infant in this State notice that one or both eyes of such infant are inflamed or reddened at any time within two weeks after its birth, it shall be the duty of such midwife or nurse so having charge of such infant to report the fact in writing, within six hours, to the health officer or some legally qualified practitioner of medicine of the city, town, or district in which the parents of the infant reside."

Health Legislation in Congress.—A large number of bills, more or less important, always fail of passage at the short session of Congress on account of the lack of time, and this is the case even when there is no special opposition to them and they have no political bias. Some of these measures related to the public health, such as the Paddock Pure Food bill, which attempted to put restraints upon the adulteration of articles of food when transported from State to State. The Conger Lard bill suffered the same fate, but this was not so desirable a measure as the other, and had been repudiated by some of the associations interested in health legislation, while the pork-packers were said to favor it. Bills for the inspection of live cattle and hogs, when exported, and of the dressed products of the same, together with an inspection of the vessels themselves, failed to become laws. However, a bill was passed prohibiting the introduction into the United States of any adulterated article of food or drink.

Is Cremation Popular?—The papers chronicle an occasional cremation of well-known persons, but it would seem that the general patronage of the crematories has not increased much within the past two or three years. The latest instance of the kind is that of Miss Emma Abbott, whose body was cremated at Pittsburg on February 17th. A short time since, a resident of Brooklyn named Meyer died and directed that his body should be cremated and the ashes thrown to the winds from the top of the statue of Liberty in New York harbor. The papers report that the direction was complied with.

Manufacturing Establishments as Nuisances.—Cases involving the question of what constitutes a nuisance which can be abated by injunction, or for which money damages can be awarded, are growing more numerous as the conditions of society become more complex. Many of the cases, and perhaps the majority, turn on points of health, and a recent action in New York is of this character. The statement of the facts shows the necessity for some legal interference. It says the nuisance is "an establishment for the manufacture of paving and roofing material, where the owner heats and boils asphaltum and other substances, which emit offensive and unwholesome gases and stenches which render the air in the locality of the plaintiff's dwelling foul and unwholesome; that by reason thereof plaintiff and his family have been put to inconvenience, discomfort, sickness, and damage; have been obliged to keep the doors and windows of their dwelling closed day and night, even in hot weather; that their food has been impregnated by such gases so as to be disagreeable to the taste and unwholesome; that fine sand and soot, and other matter engendered in the defendant's factory, have been blown into the plaintiff's dwelling to such an extent that plaintiff and his family have been deprived of the use of the front room; that plaintiff and his family have been deprived thereby of the ordinary and comfortable use and enjoyment of said dwelling and premises; that the plaintiff's wife and family have been made sick by said smells, sand, and stenches, and one of the plaintiff's daughters died from sickness caused or aggravated thereby; that plaintiff has been deprived of the services of his wife and children by reason thereof, and has been com-

pelled to pay for medical attendance on account of such sickness." The Court held that these circumstances fully warranted an action for damages.

COMPLETE OUTWARD DISLOCATION OF THE RADIUS AND ULNA AT THE ELBOW.

BY A. B. ISHAM, M.D.,
OF CINCINNATI.

IN THE MEDICAL NEWS of Sept. 30, 1882, I reported a case of complete outward dislocation of the radius and ulna at the elbow, appending a list of all the published cases of that accident that had appeared in this country up to that date—eleven in all, including my own case. To these should have been added a case reported by Dr. S. R. Towne, of Enfield, Mass., in the *Medical Record* of May 8, 1880, but which was overlooked because it appeared under an incorrect heading and was so indexed.

Recently another instance of this casualty has been met with. About midnight of Sept. 3, 1889, Mr. ——, a German, aged fifty-seven years, of spare, slight figure, while making his way home down a steep hill, lost his balance and was precipitated into a gully. His outcries aroused the dwellers in the neighborhood, and a telephone being convenient medical assistance was soon at hand. Complete outward dislocation of the radius and ulna at the right elbow-joint was found. The articular surfaces of all the bones concerned in the formation of the elbow-joint could be plainly felt. The finger could be placed in the olecranon depression of the humerus, the coronoid process of the ulna being posterior and against the external condyle of the humerus. The forearm was freely movable like the "sweep" of a flail. The increase in the breadth of the joint transversely, noted in my former case, was here particularly marked, together with the increase in the antero-posterior thickness to the outer side of the articulation, from the posterior displacement. At the inner side the internal condyle was very prominent, and there was great thinning antero-posteriorly, corresponding to the articulating surface of the humerus. There was also a right lateral deviation of the common tendon of the triceps. It may have existed also in my first case, but if so it escaped observation.

With the aid of a stout German, who held the humerus fixed, reduction was without much difficulty accomplished. I strongly extended and flexed the forearm with the left hand, while at the same time making forcible traction in a direction downward, inward, and backward with the right hand over the upper extremities of the radius and ulna anteriorly. After a few efforts in this way the double shock was felt—feeble but none the less agreeable—that announced that the bones had glided back into their proper positions. The joint was fixed with angular pasteboard splints, the forearm being held at a right angle and supported by a sling. After three days the splints were removed, and while the arm was still to be carried in a sling, gentle movements of flexion and extension, to be gradually increased in force, were directed to be practised several times daily. The result has been very gratifying, as there is no stiffness of the joint, flexion is perfect, and extension is almost complete. There being such an extensive tearing up of the structures of the joint with this luxation—the anterior and posterior and both lateral ligaments in all probability being ruptured—it is important to prevent the formation of strong adhesions by movements begun early and often repeated. In my former case, although early movement was recommended, the patient through fear of physical pain did not carry out the directions, and some adhesions formed, interfering to some degree with extension, although for this form of dislocation the outcome was unusually good and the arm is about as useful as it ever was.

In both my cases the dislocation was first backward, as shown by the position of the coronoid process of the ulna upon the posterior surface of the external condyle of the humerus. In all cases of direct fall where the arm is thrown out as a support, dislocation is commonly backward, that being the direction in which the force is most naturally distributed at the elbow-joint. A true outward dislocation would likely occur only where the weight of the body is suspended by the arm, as in dragging or being caught up by machinery, or in any event where the forearm is twisted outward, the weight of the body sustained from it being in the opposite direction. Such complete outward dislocation of the bones of the forearm at the elbow is unquestionably of rare occurrence. But if complete outward dislocations, in whatever way they may be brought about, may be included, then the accident, while it is not frequently met with, is not nearly so rare as it has been represented. This conclusion has been reached not only from my own experience but from letters received from physicians in different parts of the country after the publication of my first case, in which, after giving an account of cases they had met with, the opinion was expressed that the instances were not nearly so uncommon as the published list of cases would indicate, but, unaware of their rarity, that there had been failure on the part of the profession to report them.

The special and general works treating of dislocations devote but little space to outward luxation of the forearm bones at the elbow, and the points particularized as having diagnostic significance are the mobility of the bones entering into the joint and the ability to distinguish the articulating surfaces of the radius and ulna externally and the humerus internally. So far as I have seen, no mention is made of the peculiar appearance of the parts, the broadening of the joint, the thinning antero-posteriorly at the inner side, and the thickening in the same direction at the outer side, presenting to the eye a figure so striking that, with almost unerring accuracy, a diagnosis might be predicated upon it.

The case of Dr. Towne, previously alluded to, one case reported by Oscar Leedom in the *Med. and Surg. Reporter*, June, 1883, one case reported by Dr. W. C. Stick in THE MEDICAL NEWS for March 3, 1883, together with the case the subject of this paper, bring the whole number of cases reported in the United States, to this time, to fifteen.

THE one hundred and twenty-fifth annual meeting of the Medical Society of New Jersey was held at Long Branch, June 23 and 24, 1891. Many availed themselves of the cordial invitation extended to members of the medical profession and their families

ORIGINAL LECTURES.

HEMIPLEGIA.

Abstract of a Clinical Lecture delivered at the Bellevue Hospital.

By W. H. THOMSON, M.D.,
VISITING PHYSICIAN.

Gentlemen: The diagnosis of hemiplegia is easy to make, because the symptoms are well defined and usually unmistakable. From the standpoint of treatment, hemiplegia is scarcely a nervous disease, but rather a pure accident, resulting from disease elsewhere than in the nervous system. Our topic for to-day is, How can we prevent this great calamity?

The symptoms vary greatly, according to the seat of the accident. For instance, this man tells us that he first felt dizzy while standing, and that the dizziness was quickly followed by weakness and inability to stand. After reaching the hospital his mind was confused for only a short time. No headache had preceded the attack, and there were no other symptoms. This second patient says that, previous to his attack, there was some headache, which was not continuous. The first symptom was failing memory—he forgot words and could not perform mathematical tasks. This was followed by loss of power in the right arm and, one week later, in the leg, and then he was unable to use words.

There are three common forms of hemiplegia. The commonest follows disease of the bloodvessels, in which the coats of the arteries are rendered brittle by changes that are most readily appreciated by examination of the radial and temporal arteries. This form is called vascular hemiplegia. The form next in frequency is due to syphilitic disease, manifesting itself by changes within the skull, which are either vascular or extra-vascular. The latter are more common, and affect the brain or its coverings. These changes consist in the formation of syphilitic new growths in different parts of the brain, most commonly in the meninges. This extra-vascular form of hemiplegia is usually characterized by headache, preceding, accompanying, and frequently following the hemiplegia. In the vascular variety the hemiplegia is due to a syphilitic change in some of the arteries. It differs from the other vascular form of hemiplegia in that the arteries of the whole body are not affected, the deposits occurring here and there in the bloodvessels. This condition is not so often followed by rupture of an aneurismal dilatation as is the more usual form of vascular disease. As the syphilitic deposit gradually encroaches upon the lumen of the bloodvessels the disease shows itself somewhat slowly. In the third variety of hemiplegia the accident arises from the plugging of a bloodvessel in the brain by an embolus.

The differential diagnosis of these three varieties is of considerable importance; it is for this reason that so much time has been devoted to an examination of the arteries. This should be done quite independently of the condition of the pulse. The fingers should be placed upon the radial artery, the wrist slightly flexed, and the sensation conveyed by the bloodvessels, independently of the pulse, carefully noted. If the artery can only be detected by its beat, the vessel is healthy. If, on the other hand, the artery feels like a cord, either smooth or rough, the vessel is diseased. The vessel may feel so rough that as the finger is passed up and down, the vessel feels like a string of beads. Do not examine the pulse until after you have inquired into the condition of the artery; simply counting the pulse is but a small part of your duty.

There are six elements of the pulse to be noted, and these may be divided into two classes—*i. e.*, the cardiac and the vascular elements, dependent upon the heart's action and upon the condition of the bloodvessels respectively. The three cardiac elements are frequency, strength, and rhythm. The three vascular elements are size, quality, and length. The frequency of the radial pulse depends in nearly all cases upon the frequency of the heart-beats. The only exception to this arises when the calibre of the arteries is so much reduced by disease that the heart has great difficulty in driving the blood through them. This extra work causes hypertrophy of the heart; after a time the hypertrophied heart undergoes degeneration and dilates. When this dilatation becomes decided, the heart may have only sufficient force to propel the blood into the more distant arteries at every other beat. The strength of the pulse depends upon the force of contraction of the left ventricle of the heart. The rhythm of the pulse applies to its regularity or irregularity. By size is meant whether the pulse is full or small; if large, the artery is relaxed; if small, it is contracted. The size of the arteries is incessantly varying. By the length of the pulse is meant the time required for the pulse-wave to pass under the finger. If the artery, arterioles, and capillaries are all relaxed, so that the blood can pass rapidly through them, the pulse is short; but if there be much peripheral resistance, the pulse is long. The quality of the pulse is a most important element; it refers to the compressibility of the pulse. To determine this element, three fingers are placed upon the artery; lifting two, the third is pressed upon the bloodvessel; it is noted whether or not this manœuvre easily stops the current of blood so that it cannot be appreciated when the other fingers are again applied lightly to the vessel. If this stoppage cannot be readily accomplished, it is evident that the pulse is incompressible or hard.

Let us now see what are the practical applications of this knowledge. In case of phthisis the pulse is very compressible, but in Bright's disease or in gout it is not. Pressure sufficient to control the pulsation in phthisis is not at all adequate to control the pulse in Bright's disease. The difference in the compressibility of the pulse is particularly noticeable in two diseases that are often confounded—*i. e.*, rheumatism and gout. In the former the pulse is compressible, in the latter it is incompressible. So great is this difference that I believe, blindfolded, I could by this means distinguish between cases of rheumatism and gout.

When called to a case of hemiplegia, the first question that should suggest itself is: To what extent are the arteries diseased? The answer will influence both the prognosis and the treatment. The gravity of accidents should always be mitigated by an element of prevention, and the duty of prevention rises in importance with the seriousness of the accident. No accident can be more serious than that of paralysis; hence, the question of prophylaxis demands serious consideration. In the first

patient the artery can only be felt on the diseased side by its throb; the vessel is like that of one in health. On the sound side it can just be felt, because on this side the circulation is a little stronger. The case is either one of syphilis or of embolism, as a result of which there is hemiplegia; the patient is not old enough to show vascular changes of a non-specific character; he has not used alcohol immoderately, nor is he the subject of Bright's disease. The temporal arteries are not tortuous or prominent; this also leads us to think that the general arterial system is sound. The hemiplegia, then, is most probably due to syphilis or to embolism. Neither the history nor the physical examination points to cardiac disease, so it is not likely that there is embolism. I am, therefore, led to suspect that the hemiplegia is of syphilitic origin. The patient denies having had headache, but this is not incompatible with the theory of a syphilitic endarteritis; besides this, the hemiplegia came on gradually—first in the arm and then, about one week later, in the leg. The other patient is older, and evidently has a higher degree of vascular disease than the first patient, but by no means enough to account for his condition. His pulse is quite compressible; such a pulse is not likely to be present in a case of vascular hemiplegia. The reason for this is found in the physical conditions that determine the compressibility of the pulse, and on these the prophylactic treatment is based. It is the rule in all cases of vascular disease that the small arteries are more extensively diseased than the large ones. A hard, incompressible pulse indicates that the bloodvessel is much distended, owing to the difficulty of forcing the blood into the arterioles. If the force of the heart's action be suddenly increased by excitement, it is easy to understand that the coats of the bloodvessel might yield, forming an aneurism which, under similar conditions, might eventually rupture.

There are two ways in which the lumen of an artery may be narrowed, viz.: (1) by vasomotor contraction and (2) by disease of the arterial coats. By a nervous impression the calibre of the arteries may be so narrowed that no blood can get through. Fear gives rise to a sudden blanching of the face and a violent, tumultuous action of the heart from the consequent increase in peripheral resistance. If the heart is not equal to this emergency sudden death is the result. In this way death from drowning often occurs in good swimmers, by suddenly throwing upon the heart extra work, owing to the sudden contraction of the arteries all over the body, as a result of a plunge into very cold water. Similarly, if the heart be unable to furnish an adequate supply of arterial blood to the muscles, muscular cramp is produced.

Whatever causes irritation of the vasomotor nerves may produce an over-full artery just as perfectly as though the artery itself were diseased. Vascular disease leading to hemiplegia is in a large majority of cases due to a slow chronic interstitial nephritis, represented by the red, contracted kidney. Cases of this kind are characterized by the presence of a moderate amount of albumin in the urine, often entirely absent for days at a time. The urine is of low specific gravity and pale in color, from the deficiency in the coloring-matter that should have been removed from the blood. Under the microscope you will find almost constantly hyaline or granular casts, showing that structural changes are going on in the kidney. The bloodvessels are irritated by the excrementitious matter that is not removed by the kidneys, and the result is a chronic endarteritis. An analogous change is also very often present in the veins. Bright's disease also has a great tendency to produce "nervous storms," sudden changes in the conditions of the vasomotor nerves, that, in ordinary language, are spoken of as a "rush of blood to the head." Even in health, the urine excreted after a hearty meal is of much higher gravity and contains much more urea than the urine excreted before the meal; this is due to the fact that there is a special vasomotor arrangement for all the excretory apparatus of the body, that provides for more active secretion when an addition has been made to the system; hence, when a full meal is taken extra work is thrown upon the kidneys, in order to preserve the balance of the circulation, and if the kidney is too much damaged to do this extra work, the vascular system may suffer serious derangement. It is on this account that so many cases of hemiplegia or apoplexy occur just after a hearty meal. We see, then, how a proper understanding of the relations of the vasomotor system, and its bearing upon vascular disease, may enable us to prevent the development of the diseased conditions just described, and so avert that great calamity, hemiplegia.

TUBERCULOUS ULCERATION OF THE SKIN AND GLANDS.

A Lecture
delivered at the Philadelphia Hospital.

By ERNEST LAPLACE, M.D.,
PROFESSOR OF PATHOLOGY AND CLINICAL SURGERY IN THE MEDICO-CHIRURGICAL COLLEGE; SURGEON TO THE PHILADELPHIA HOSPITAL.

I bring before you a little child, with what seems to be an ulceration of the neck. It behooves us to establish a diagnosis, because the child is very ill, and we must act at once. I call your attention to the temperature, which, in the morning, is about 99°, or a little lower, and in the evening rises to about 103°, or a little higher. The pulse varies between 120 and 140. The child has a delicate appearance, and we find the neck swollen and a certain amount of ulceration. We have to determine the nature of the pathological condition. We must do something for the child, for, in spite of treatment, the temperature remains elevated. What is the cause of this elevation of temperature? Should we operate and remove the tumor regardless of the temperature? Is this ulceration the cause of the elevation? If it is, we must operate notwithstanding the elevation of temperature, for not until the disease is removed will the fever disappear.

Let us examine the case. Here is a mass extending from the angle of the jaw almost to the clavicle, a large tumor, on the surface of which the skin has ulcerated. Between two ulcerations is a bridge of skin, which furnishes a clue to the diagnosis, because the condition of the skin, with underlying ulcerations, is the same as in the case of lupus which we saw, and for which you should always look when you suspect tuberculosis. Coming from this ulceration is a grumous, cheesy substance,

which consists of epithelial cells that have undergone fatty degeneration. Examining the location of this tumor, we find that it exists over the region of the cervical glands; that these are enlarged, and that they are not freely movable on the subjacent structures. Because a tumor is not freely movable, you need not necessarily conclude that there is an infiltration of the underlying structures by the disease process. You know that in the differential diagnosis between carcinoma and benign growths we palpate to determine whether the growth is movable or immovable. If movable, it is a sign that it has not thrown roots (if you will pardon the expression) into the subjacent tissues. If immovable, it is a sign that it has thrown its roots into the underlying structures. In this case the tumor is only slightly movable. This is not due to infiltration; the tumor is simply bound down by the tissues about it. This has been of gradual development, and the child has not been well at any time since the process began. It first grew as a hard lump, softened, and then ulcerated, and is an example of tuberculosis of lymphatic glands.

Aside from this I draw your attention to a few points: Blonde children are more disposed to develop tuberculosis or scrofulosis than brunettes; fair-haired, blue-eyed, light-skinned children are more likely to develop one or the other of these diseases.

This child was brought here a few days ago by the mother, and as we have not seen the latter since, we cannot operate now, as we had intended. In the meantime we will give the child tonics, in order to put it in the best possible condition. As a rule, in these cases, not one or two, but a great many glands are affected. As they are deeply situated around the carotid artery and jugular vein it becomes a delicate operation to remove the glands completely, usually necessitating careful dissection from the clavicle nearly up to the angle of the jaw, and this requires time and attention.

The next case is a patient who also has an affection of the glands, and here I want to differentiate these two affections. This man was struck by a rock, and as a result received what is called a contused lacerated wound of the scalp. Not a sharp, incised wound in which the bloodvessels are cleanly cut and no harm is done to their structure, but a contused wound from a blunt instrument, as a result of which the bloodvessels are bruised and neighboring cells destroyed. Such a wound will not heal by first intention, because the cells have been destroyed outright. Wounds of this kind are dangerous, because a certain amount of tissue is of necessity destroyed, and there is sloughing of the parts; the wound may also be easily infected, and there may be other trouble to contend with. There may be infection of the parts and the attendant results: general septicæmia or pyæmia, or, what is of less importance and what has taken place in this case, a local infection which has been intercepted by the lymphatic glands in the neighborhood. This man came to the hospital without being able to tell us much about the wound. He said he suffered from a lump on the side of the neck. It would be a mistake to operate in such a case without considering the possibility that the tumor might have some connection with the contused and lacerated wound of the scalp, though on the opposite side of the head.

Inasmuch as this growth has developed after the reception of the wound on the head, and inasmuch as it presents certain acute symptoms (being red and painful), we know that there is taking place in that gland a certain acute process; what is it? Nine-tenths of all acute processes of this kind are either directly or indirectly due to the local development of the streptococcus pyogenes aureus, the local germ of suppuration, with which we must become acquainted just as intimately as we are with the alphabet, for we never get an abscess or any suppuration without the presence of these germs, at least when the trouble has been produced by an infection. Later I shall have occasion to speak to you of aseptic pus, in which there are no germs, which is produced by chemicals, such as corrosive sublimate, and which, acting on the skin, produce pus without germs; but all these acute processes, resulting from local infection, contain this germ, and we must learn all about it. Here we have a swelling, a tumor, which is painful, but not well defined. We do not find it as a mass under the skin, but sloping in all directions. It is painful not only at its summit, but also in the neighborhood thereof. Not only is the gland below affected and the seat of an inflammation, but the tissues about it are more or less infected. Recognizing that the process is gradually extending, we know that the cause is still present, and that unless it is removed only one thing can follow, and that is local suppuration.

Through the wound in the scalp germs have found entrance, and received by the gaping mouths of lymphatics, they have travelled down to this gland, which has strained the lymph and retained the germs. Here in the gland, just as in the test-tube in the pathological laboratory, a colony develops at the expense of the substance upon which the germs grow. Blood comes to the part, white blood-corpuscles are killed; they collect as pus and an abscess results. This will occur unless one thing be done. If we wish to stop the growth of the germs, we must enter the parts with an agent which will destroy them. Agents of this kind are called antiseptics. We must open the wound in the scalp, carefully cleanse it, removing all dead tissue, and apply antiseptic dressings, which will not only destroy the germs now present, but also prevent other germs from entering the system. That being done, our attention must be directed to the infected gland. How must we treat this? Please remember that you must never apply a poultice under such conditions as here exist. Never, because you have a swelling, apply a poultice. What do we accomplish with a poultice? We bring the affection to a "head," which means promoting the development of germs and the formation of pus, which is the reverse of what we wish to do. Therefore, do not put on heat and moisture, which would supply the favorable conditions for the development of germs. We must place there moisture, if you wish, but moisture in conjunction with something which, when it penetrates the skin, will destroy the microorganisms; the inflammatory process being stopped, no abscess will be formed. Therefore the treatment is the continuous local application of an antiseptic; not warm, of necessity, but cold. Generally, the modern poultice is antiseptic. Instead of simple warm water, with the flaxseed meal, use a 1 to 1000 solution of corrosive sublimate, or a 1 to 2000 or 3000 of the acid sublimate, and keep the poultice applied to the parts. The flaxseed meal

retains the moisture and retards evaporation. The antiseptic solution will penetrate the parts, causing contraction of the bloodvessels and destruction of the germs, and will check the inflammatory process going on.

CLINICAL MEMORANDA.

BROMOFORM AS A TOPICAL APPLICATION.

BY SOLOMON SOLIS-COHEN, M.D.,
OF PHILADELPHIA.

I HAVE recently employed bromoform in a severe case of ozæna as a topical application to the nasal mucous membrane after thorough cleansing with hydrogen dioxide. The absence of the severe local reaction anticipated, together with the extraordinary success of the measure, not only in destroying the odor but in controlling the morbid secretion, encouraged me, after preliminary trial upon my tongue and pharynx, to use the same agent as a topical application to tuberculous and other ulcers of the larynx, after cleansing with hydrogen dioxide. Here the agent seemed to exert analgesic as well as disinfectant properties, as pain was relieved and healing apparently promoted. The agent being extremely volatile, the immediate effect is transient, and I have, therefore, followed the application of bromoform with insufflation of iodoform in powder. While this somewhat obscures the therapy, yet the effect was better than when iodoform had been used without bromoform in the same cases. This preliminary note is published at this time to induce further trial and report by others.

219 S. 17TH ST., JUNE 15, 1891.

MEDICAL PROGRESS.

Diphtheria.—LÖFFLER, RAUX and WACHSMUTH contribute in the *Jahrbuch für Kinderheilkunde* the following:

Patients with diphtheria should, of course, be isolated, and placed in a room containing only the barest necessaries in the way of furniture. All the surroundings of the patient must be freed from bacilli by the use of superheated steam. Children who have had diphtheria must be kept out of school at least four weeks. The resisting powers of the bacillus of diphtheria are such that it can retain its vitality in large and moist membranes for from fourteen to sixteen weeks. Löffler is not quite certain that diphtheria can be transferred from animals to human beings, but he believes that the bacillus may locate upon unbroken mucous membrane; hence, for prophylactic purposes, the necessity of the use of mouth-washes for children. A 1 : 10,000 solution of sublimate may be used for this purpose. He does not believe that climate has so much to do with the danger of contracting this disease as bad hygienic conditions. His conclusions are:

1. The diphtheritic spore is the cause of the disease, and is to be found in the diseased mucous membrane.

2. So long as any traces of diphtheritic exudate remain, the bacillus or spore may be found, and in some cases it may be found after such traces have disappeared.

3. In dry membranes the spore will retain its vitality four or five months; hence the necessity for disinfecting everything which might come in contact with the diseased excretion. This may be done by boiling, or by subjecting to steam at 100° C. The floors should be washed with a 1 : 1000 solution of sublimate, and the walls rubbed with bread.

4. The bacilli retain their vitality longer in moist than in dry surroundings, hence moist and dark rooms are favorable for their development.

5. The bacillus of diphtheria thrives very well outside the body, at a temperature of 20° C.; it also grows very well in milk; hence the necessity for careful regulation of the milk business.

6. The diseases which resemble diphtheria in certain animals are not caused by the bacillus that causes diphtheria in human beings, nor will the former give rise to diphtheria in human beings.

7. The etiological identity of diphtheria in cats with that in human beings has not been proven.

8. Lesions of the mucous membrane favor the development of the bacillus of diphtheria, but are not essential thereto.

9. The influence of certain meteorological factors in determining the spread of diphtheria has not yet been positively shown.

Roux affirms that the diagnosis of diphtheria cannot be bacteriologically determined with certainty until the middle of the second day of the disease.

In regard to treatment: the use of antiseptic irrigation must be continued until the bacilli have disappeared from the mouth. Such treatment should continue from eleven to fourteen days. The furniture of the sick-room and all the surroundings should be disinfected with boiling water or steam, the patients should be isolated, and antiseptic irrigation should be continued as long as any trace of angina remains.

Wachsmuth recommends the following prophylactic precautions:

1. The yard contiguous to the house in which diphtheria has prevailed should be disinfected.

2. Places in which dust accumulates should be disinfected with carbolic acid, and the dust collected and carried away.

3. Means for producing perspiration are among the most efficient agents in the prophylaxis of diphtheria. —*Archives of Pædiatrics*, May, 1891.

Opening of the Mastoid Process.—HEIMAN says: Throughout Europe the mastoid process is opened with the hammer and chisel. I also operate principally in the same manner, and until lately only with the chisel, as this method is the least dangerous, the wound remaining clean during the operation, and easily kept under observation. A few months ago the surgical department of the hospital received a trephine à crémaillère for operations on the bone. It is precisely the same trephine which Pasteur uses in his investigations on animals. I was advised to use the instrument for opening the mastoid process. I have done so twice, and once the operation was done by the consultant of the surgical department. No conclusions can be drawn from these three operations, and I shall therefore confine myself to giving the impressions which this method of operating made upon me:

1. The removal of the compact portion of the mastoid

process, especially when it is thick, is much more rapid than with the mallet.

2. The edges of the wound need not be smoothed off after the operation.

3. The different size of the trephines permits the formation of a wound in the bone of the desired size.

4. Shock, which can be avoided with the hammer only to a certain extent, is entirely obviated with the trephine.

5. The depth of the wound can be graduated with exactness.

An inconvenience, however, lies in the fact that the wound can only be inspected when the trephined piece of bone has been lifted out, which in sclerosed bone may not be easy. For operating in the mastoid cells the sharp spoon is sufficient. The true value of this method can be ascertained only after a large number of operations, performed by various surgeons. I believe that in opening the cranial cavity for the evacuation of cranial abscesses the trephine is to be preferred even to the broad chisel, because in removing a large piece of bone with the latter instrument we must operate a long time with it, so that the shock must be quite severe, which with the trephine is not the case, even when applied at several adjacent spots.—*Archives of Otology*, April, 1891.

Rheumatic Hyperpyrexia Without Cerebral Symptoms.—ROSENTHAL (*Deutsche medicin. Wochenschr.*, No. 11, 1891) reports a case of rheumatism in a male, thirty-one years old, that for a week ran the usual course, the temperature not rising above 102.2°. There was sleeplessness, which resisted treatment with morphine and chloral. On the eighth day the temperature suddenly rose to 104°, and the breathing became bad. From 104° at 5 P.M., the temperature rose to 105.8° at 10 P.M., to 108.9° at 12.45, and to 110.5° ten minutes later. Death took place at 1.30 P.M., when the temperature reached 111.6°. Sweating, which earlier had been rather profuse, gave way, with the setting in of the hyperpyrexia, to a hot, dry skin. Consciousness was retained until within an hour and a half of death, with entire absence of cerebral symptoms.

A Case of Multiple Sclerosis with Intention-tremor in the Face.—COHN (*Deutsche medicin. Wochenschr.*, No. 13, 1891) reports a case of multiple sclerosis, in which intention-tremor of the muscles of the face was present, and in which the differential diagnosis from paralysis agitans was, to say the least, exceedingly difficult. The patient was a woman of thirty-four, without neurotic family history, save, perhaps, for tremor and impairment of gait in the mother. Following a labor, some difficulty in walking was noticed, and later, tremor in the left arm on attempted movement. Speech was said to have been affected. The condition became aggravated after a subsequent labor. The tremor advanced to the right arm, and there were pain and stiffness of the neck. The facial expression was fixed; muscular movements were performed tardily, and were accompanied by tremor of the eyelids and lips. The chin-reflex was emphatic. Tremor of the upper extremities continued during rest, but was more marked when attempts at movement were made. The fingers were fixed as in writing, the middle, ring and little fingers of the left hand being in constant motion. Change from the sitting posture to the erect was performed slowly and was attended with tremor of the extremities. The gait was propulsive; the forearm was flexed on the arm, the hand on the forearm. Passive movement of the rigid parts caused pain. There was spontaneous pain in the back; also restlessness, readiness of fatigue and sense of heat. The right half of the body was weaker than the left. In favor of the diagnosis of paralysis agitans were the constant tremor, the weakness, the rigidity, the facial expression, the position of the hands and arms, the propulsive gait, the pains, the sense of fatigue and the restlessness, the sense of heat, without elevation of temperature; in favor of multiple sclerosis, the age of the patient and the intensification of the tremor by attempted movement. In the further course of the disease, nystagmus, upon both lateral and vertical movement of the eyeballs, developed. As to the possibility of an association of paralysis agitans and multiple sclerosis in the same patient, Cohn could find in literature but one case. In this an autopsy revealed the presence of multiple sclerosis, the symptoms of paralysis agitans only having been present during life.

The Insane in the United States.—According to the *Abstract of Sanitary Reports* of the United States Marine-Hospital Bureau, May 29, 1891, the total number of insane persons treated in both public and private institutions during the year 1889 was 97,535, while during the year 1881 there were 56,205 treated, showing an increase in the nine years of 41,330, or 73.53 per cent. This percentage of increase, when compared with the percentage of increase of population in the last decade, namely, 24.86, does not indicate an increase in the proportion of insane persons to population, but rather a great increase in the amount of asylum accommodation provided, and a willingness on the part of the public to make full use of all the facilities thus provided. The figures for the actual number of insane in the United States cannot be determined until the work of eliminating all duplicate reports of cases has been completed.

In 1889 there were 38 private institutions in the United States for the treatment of the insane, 25 located in the North Atlantic States, 12 in the North Central States, and 1 in the South Atlantic States.

The ratio to each 1000 inhabitants of the whole United States of the insane in public institutions is 1.46, and, including both public and private institutions, 1.56.

Water Supply and Tapeworm.—The citizens of Glasgow glory in their matchless water supply taken from Loch Katrine, but they are subject to periodical scares regarding alleged dangers by its use. Once it was the assertion that the water was too soft and rickets would become prevalent. Next it was the risks of contamination that would arise from the little steamers that ply the loch in the summer season, and the inevitable excretal discharges that would imperil the health of the water-consumer. Both of these suspicions lost their force when the passage of events disclosed no evil results. The latest alleged danger is a peculiar one, and exists in the fact that the trout of the lake are infested with tapeworm, but this very unsavory suggestion has been shown to be a groundless cause of alarm, by an investigation made by Dr. J.

B. Russell, the medical officer of health, and by Professor Young. These investigators report, that while it is undoubtedly a fact that trout suffer from the parasite as has been stated, yet they do not consider that there is special risk that tænious disease will be propagated through the channel of the water supply. On the contrary, it is their conviction that the records will show that there is less rather than more of tapeworm complications among Glaswegians—as Scott would term them—when compared with the residents of other localities in Scotland.

The Results of Removal of the Breast.—As a result of partial or total removal of the breast in one hundred patients, in the treatment of tumors of various kinds, between 1880 and 1889, Terrillon (*Bulletin Gen. de Thérap.*, May 15, 1891) has arrived at the following conclusions: the gravity of the operation is insignificant; recurrence seems to be the rule when the axillary glands are involved in the disease; when mammary tumors are malignant or of a mixed character, the entire gland and involved lymphatic glands should be removed if recurrence takes place; the operation may be repeated once or several times, especially if primary union of the skin can be secured; by this means the condition of the patient is ameliorated, the drain attending ulceration is obviated and the unfavorable course of the disease seems to be retarded.

The Arterial Tension in Phthisis.—Marfan (*La Méd. Moderne*, May 21, 1891) has observed that, in cases of phthisis, with or without fever or treatment, the arterial tension is, from the outset, lowered. With active fever or the approach of death, the tension falls still lower.

Œdema of the Larynx in the Course of Bright's Disease.—Mendel (*Annales des Malad. de l'Oreille*, etc., May, 1891) reports the case of a man, fifty years old, who for twenty years had noticed transitory swelling of the feet, hands, scrotum, and face. Albumin was found in the urine. On one occasion, he was suddenly seized with difficulty of speech and respiration. The symptoms became so aggravated that suffocation was feared. On examination, the velum, especially the anterior pillars, the uvula, the left pharyngo-epiglottic fold were found red and swollen, the epiglottis being displaced to the right. The throat was sprayed with carbolized water and a milk diet was prescribed. In the course of a few days the œdema had disappeared. On the posterior surface of the epiglottis a small, acuminated tumor, probably the result of chronic inflammation of the mucous membrane, was now noticed.

The Treatment of Pulmonary Tuberculosis by Vaccination.—Dochmann (*Medizina*, No. 6, 1891) reports three interesting observations made by Vinogradof in 1883–84.

In a woman of twenty-four, with pulmonary tuberculosis in the second stage, an attack of uncomplicated variola was followed by local and general improvement.

In a woman of twenty-six, also in the second stage of pulmonary tuberculosis, vaccination, repeated several times, and a single interstitial injection of cow-vaccine were followed by improvement of the general condition and of that of the lungs.

A student in the second stage of pulmonary tuberculosis, who was vaccinated eleven times, at the end of several months presented increase in weight and improvement in the general and local condition.—*La Méd. Mod.*, May 21, 1891.

Treatment of Burns and Scalds.—Having observed the good results obtained from the application of rubber cloth to wounds upon which skin has been grafted, as well as to the surface from which the graft has been taken, Dr. O. P. Barber, of Saginaw, Michigan, has suggested a similar procedure in the treatment of burns and scalds. The burned surface is freely irrigated with carbolized water, all necrotic tissue removed and blebs punctured. Then the entire wound is snugly wrapped in rubber tissue that has been kept in a carbolized solution. Over this is placed absorbent cotton and a bandage. The advantages claimed for the dressing are that it relieves pain, that it does not adhere to the wound, that it excludes air, and that it protects the granulations, whilst preventing their exuberant growth.

Artificial Quinine.—Trimaux and Arnaud (*Tribune Médicale*) have succeeded in producing quinine synthetically by the addition of cuprein (a base obtained from the Remijia pedunculata, a shrub or tree of Brazil belonging to the natural order of Rubiaceæ or Cinchoneæ) carefully purified and freed of all traces of quinine, to a theoretical quantity of sodium dissolved in methylic alcohol. The mixture is for several hours gradually heated with an excess of iodide of methyl. The result is quinine or methyl-cuprein. By a secondary reaction iodomethylates of quinine also form, similar to those furnished by natural quinine. Conducting the process in a closed vessel, the di-iodomethylate of quinine is obtained, the properties of which are identical with those of natural quinine. If the iodide of methyl be replaced by the chloride of methyl, so that a mixture of a molecule of cuprein, an atom of sodium, and a molecule of chloride of methyl results, which is dissolved in methylic alcohol and heated for twelve hours in sealed flasks at 212°, one obtains free quinine.—*Les Nouveaux Remèdes*, May 24, 1891.

The Puerperium in Malarial Districts.—From a study of forty-six cases in which malaria existed during the puerperium, Abelin (*Archives de Tocologie*, March, 1891) concludes that malaria does not affect the progress of labor, that it does not perceptibly influence normal uterine involution and that it is questionable if it affects the secretion of milk. It is the cachexia due to chronic malaria, rather than the malaria itself, that predisposes to the occurrence of post-partum hemorrhage. Acute intermittent fever, however, appears to predispose to the occurrence of hemorrhage and to a prolongation and increase in the quantity of the sanguinolent lochial discharge. The appearance or reappearance of malarial manifestations after labor is frequently observed; but labor is often followed by a disappearance of the signs of malaria which had been present in the later months of pregnancy. It is difficult to be certain that febrile attacks in the puerperium are malarial in character; it is first necessary to exclude local causes of high temperature in the genital organs and in the breasts. Malaria does not appear to be more intense in the puerperium

than at other times and if promptly treated it does not constitute a serious puerperal complication.—*Edinburgh Medical Journal*, June, 1891.

Transmission of Tubercle Bacilli from Mother to Fœtus.—BIRCH-HIRSCHFELD and SCHMORE (*Beitr. zur Pathol. Anat. u. zur Allgem. Pathol.*, 1891, p. 429) have reported the case of a young woman, who, early in her first pregnancy presented signs of phthisis, to which she succumbed in the seventh month. Immediately after the death of the mother, the fœtus was extracted by Cæsarean section. On post-mortem examination tuberculosis was detected not only in the lungs but also in other organs of the mother. Although the fœtus had been alive shortly before the death of the mother, it was dead when removed. The chest was at once opened, but nothing abnormal was found in the lungs. The surface of the abdomen was washed with a solution of bichloride of mercury and the cavity opened with sterilized knives. No tubercles could be seen. Small bits of the liver, spleen, and kidney were, with antiseptic precautions, placed in the abdominal cavities of two guinea-pigs and a rabbit. One of the guinea-pigs died in fourteen days. The other was killed at the end of six weeks, and many tubercles were found in the peritoneal cavity. The rabbit lived for three months. On its death many tubercles were found in the liver and lung. Tubercle bacilli were found in the umbilical cord and in the blood of the umbilical vein of the fœtus.—*Supplement to Brit. Med. Jour.*, June 6, 1891.

A New Method of Staining the Bacilli of Leprosy and Tuberculosis.—UNNA (*Monatshefte für prakt. Dermatol.*, June 1, 1891) proposes a new method of staining the bacilli of leprosy and of tuberculosis. By carrying out the following procedures the bacilli are stained brownish-red upon a colorless background.

1. Stain for five minutes in an aqueous borax-methylene-blue solution (1 : 1 : 100).
2. Wash in water.
3. Iodize for five minutes in a 5 per cent. solution of potassium iodide, containing a crystal of iodine.
4. Wash in absolute alcohol until blue clouds are given off.
5. Differentiate in creasol from a few seconds to half a minute.
6. Fix in rectified oil of turpentine.
7. Mount in balsam (a solution of yellow resin in oil of turpentine).

The method may be modified in the following manner for staining tissues:

1. Stain for five minutes in an aqueous solution of borax-methylene-blue (1 : 1 : 100).
2. Wash in water.
3. Iodize for five minutes in a 5 per cent. solution of potassium iodide.
4. Wash in absolute alcohol.
5. Differentiate from ten to thirty seconds in a solution of equal parts of glacial acetic acid, absolute alcohol and ether.
6. Harden and smooth by immersing in absolute alcohol.
7. Fix in rectified oil of turpentine.
8. Mount in balsam (a solution of yellow resin in oil of turpentine).

Good results may be obtained by omitting the fifth and sixth manipulations.

Remedy for the Stings of Insects.—As the result of personal experience, DR. WM. A. TERRY (*Dietetic Gazette*, June, 1891) recommends the application of fresh urine in the treatment of the stings of venomous insects. The application is soon followed by a subsidence of the pain and a disappearance of the inflammation. The effectiveness of the result depends upon the speediness of application. It is thought that urea is the active agent in the antagonism.

Pambotano—A Substitute for Quinine.—DR. A. E. ROUSSEL presented to the Philadelphia County Medical Society a report of eight cases of malarial fever, in the treatment of which an alcoholic elixir of pambotano or calliandra houstoni was used. Ninety grammes of the elixir, representing seventy grammes of pambotano, were administered in four equal doses, in hot, sweetened water or tea, in the course of twenty-four hours, preferably on an empty stomach. The results, while encouraging, were scarcely so satisfactory as those reported by other observers. Used in influenza, typhoid fever and phthisis, no influence upon the course of the diseases could be observed.

Saturnine Hemichorea.—GIRAT (*L'Union Méd.*, May 7, 1891) reports the case of an artisan, whose occupation necessitated the handling of red lead. He suffered with habitual constipation, and there was a blue line at the margin of the gums. One night he was suddenly awakened by a sense of formication, cramps, and irregular involuntary movements, beginning in the right leg and extending to the right arm. The intelligence was preserved; there was no fever, no paralysis. The breath was fœtid, the abdomen tender but not retracted. A sedative was prescribed, and an enema administered. On the following day the movements continued; in addition, attacks of clonic convulsions occurred. The abdominal pain increased in severity; nausea and bilious vomiting set in; the right half of the anterior abdominal wall felt hard, as if the muscles were spasmodically contracted. The enema was repeated. In the course of a few days the symptoms gradually and completely subsided.

Tuberculous Peritonitis in a Child, Cured by Abdominal Section.—ALEXANDROFF (*Wratch*) reports the case of a girl, three years and nine months old, whose father had died of tuberculosis. Diarrhœa had existed for two months; the abdomen was enlarged; dulness on percussion and fluctuation were elicited; the temperature ranged from 100° to 102°. Abdominal section was performed, the fluid evacuated, and drainage provided. A bit of peritoneum, examined microscopically, contained tubercles and giant-cells. The wound healed by primary union. The fever, however, persisted, and the fluid reaccumulated. The operation was repeated, the abdominal cavity being irrigated with a solution of boric acid. The fever now declined, the patient began to increase in weight, and eventually recovered.—*Revue Obstét. et Gynécol.*, April, 1891.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

PHILADELPHIA.

SATURDAY, JULY 11, 1891.

THE INTERNATIONAL HOMŒOPATHIC CONVENTION.

IN reading the reports of this Convention, just held at Atlantic City, one is persistently struck by the indifference of the delegates and speakers to what would naturally seem their chief duty and concern. They did not appear to have much interest in disease, but only concern for the progress of homœopathy and in medical legislation. After two days of self-glorification, came a practical-appearing paper on "Backache." The essence of the paper and of the subsequent discussion appears to be that backache is due to knots in corset-strings, to "a non-woollen trouser waist-band," to buttons, whalebones, heavy silver watches, etc. In diagnosticating this wonderful disease we are directed thus: "After practising usual crural and abdominal reflexes (!) direct the patient to arch the back and rest on occiput and heels; request the subject to walk in a straight line, eyes shut, and at the same time play an imaginary fiddle. Some special curves disappear on patient 'dressing up' vertically and trying to look square." In the report as to the progress of homœopathy in foreign countries, we are assured that in Germany "the clouds of ignorance are being dissipated by homœopathy." In England the "slow progress" is charged to "British conservatism." "Good news" comes from China, Australia, South America, etc. "In Moscow and St. Petersburg the homœopathic physicians are pulling by far the greater number of silver door-bells." The quack, Count Mattei, upholds the flag in Italy. In America "homœopathy has received its full perfection like the other sciences."

"Insurance Discrimination" was the subject of a report "received with marked interest." Personal letters, written to the presidents of twenty-seven life-insurance companies, as to their discrimination against homœopathic physicians in the choice of examiners, elicited only eleven answers. "Sixteen entirely ignored the request." The few replies are highly amusing. The question is dodged by most of the presidents; one can picture the wicked smiles that probably played about the grim visages of the writers as they dictated their answers. The officer was absent whose duty it was, or who "was competent," to answer the inquiry. Others aver they "never discriminate;" but the lecturer asserted most positively that the companies issue secret orders against the appointment of a homœopathist. Only one company met the question with a manly answer: "We appoint regular physicians because they are the best educated."

In considering "the ethical basis of the separate existence of the homœopathic school," Dr. Crouch contended that the "allopath" has "no more actual science than the Indian medicine man who essays to cure by blowing feathers and beating tom-toms." This slightly extreme judgment was deemed too lenient, and was reinforced by adding that the "allopathic" principle of practice is "not one whit in advance of that of prehistoric man, nor in any way changed except by the unfortunate doctrine of the illustrious GALEN."

At odd, rare intervals a live medical subject was sniffed at, much as a puppy plays with a bumble-bee. One speaker did actually advise the trial of antiseptic methods in puerperal fever. Bacteriology was ogled and snapped at, but at once there was a turning of tail and a ridiculous retreat. The bumble-bee excites curiosity, but is dangerous. "Materia medica day" (*sic*) promised a closer grappling with facts. Alas! we are again floated away on glittering generalities concerning "Civil Government and the Healers of the Sick"—in other words, our States and the general Government must not let the "allopath" have any cherries unless the homœo-

pathic boys are allowed in the same tree. There was one practical subject announced: "A Comparison of Therapeutic Methods based on a Study of Arsenic." "At his own request the speaker was excused from reading it." He was manifestly out of place—possibly, like the young neophyte of Doré's great picture, he was startled at the mediæval mummery and the kind of folk he had got among.

The fourth and fifth days also passed in much vaporous talk about homœopathy instead of about disease, an occasional slight diversion taking place as to hay-fever, appendicitis, etc. A paper on "Orificial Surgery" was noteworthy, and through her representative Philadelphia did not fail to make her voice heard in favor of "the liquor from corned beef and cabbage for cases of cholera infantum in babes as young as ten days." On the sixth day, the glorious subject being still unexhausted, "The Progress of Homœopathy in the World" was again discussed with perfervid rhetoric. But the topic nearest the heart ended all—the everlasting one of *medical legislation.*

Such a sketch as we have given, when read post-mortem, may appear like the caricature of a malignant, partisan enemy, but it is not half so absurd as the more extended report given by the best daily papers. It is strange that such things can happen here, and now. Representatives of what purports to be a great medical school for healing disease come from all parts of the civilized world, and their whole week's work is about their sect, not about disease. In all this great convention not a word is said concerning phthisis, that annually carries off about two thousand of every million inhabitants; not a word uttered by these men showed that they cared that each year, in this country alone, some forty thousand die of diphtheria. Did these "physicians" manifest any concern as to typhoid fever, to which three or four per cent. of all deaths are due? As to diseases of the digestive organs that slay their thousands? As to diseases of the circulatory and nervous systems that slay their tens of thousands? As to diseases of the respiratory system that slay their millions? Should one sit down and enumerate the percentages of deaths from each disease that afflicts humanity, and then foot them all up, it would be found that during these seven days not a paper was read nor a discussion held upon the diseases that cause about ninety-nine per cent. of the deaths of the world. And yet these people can find dupes who think there is either sense or seriousness in such a school of medicine!

However, could aught else be expected of men who almost worship one who took as his distinctive tenets of medical faith the most outrageous absurdities that can be imagined? Take away these travesties of nonsense and nothing is left of Hahnemannianism. What, in brief, simple English, are these articles of the Hahnemannian homœopathic creed?

1. That disease is immaterial, spiritual, its causes not perceptible to the senses, and that no attempt need be made to find them out.

2. That all chronic diseases, except syphilis and sycosis, are due to the itch.

3. That the more you weaken or dilute a drug with water the stronger it becomes, until all that is necessary is simply to smell the most diluted mixture—"even though you have no smeller."

4. That to put out a fire you must add fuel to it—to cure a disease give a medicine that would cause it.

Is it to be wondered at that men who pretend to believe such idiotic drivel call themselves the "new school," when they know that the real new school of medicine, with its instruments of precision, its bacteriological research and its earnest scientific zeal, should long ago have burned as in a garbage furnace *their* very "old school?" It is they only that could find satisfaction and self-excuse in dubbing as "allopathists" those who would as willingly, and could as justly, be called popcornopathists. It is only such who would pretend to practise "dynamization by attenuation," whilst secretly and hypocritically giving "allopathic" doses of "allopathic" drugs.

The moral of it all is, that to indulge in good-humored contempt of these pestiferous doctrines and doctrinaires, to show them mercy, to be indifferent to them, to compromise and play politics with them, is to be poltroon and renegade in the face of one's duty to science and humanity.

THE REPORT OF A MEDICAL EXAMINER FOR LIFE INSURANCE.

THERE are few things that suggest more significant and valuable lessons as to public health, disease, heredity, etc., than the report of a conscientious and skilled medical examiner for a well-managed life insurance company. That such reports may yield the best lessons, the examiner must be one

that does not blindly follow the statistics of others' gathering, nor mechanically carry out old-established rules. For example, to extend the system of averages over areas where diverse conditions prevail hides from view the operations of special causes and conceals the lessons of special prophylaxes. Such dangers are carefully guarded against in the perspicuous summaries of his work made by the medical examiner-in-chief of that well-known organization, the Royal Arcanum. Of 5855 applications submitted to him in 1890 by presumably healthy men, 1302 were rejected. This large proportion of rejections arouses a somewhat startling inquiry as to the general state of physical health of the average American citizen. In a membership of 105,397 the deaths were 925, or a death-rate for the order of 8.77 per thousand. As to the relative death-rates of different States, taking the average of the past five years, we learn that Arkansas was, by a large plurality, the least healthful of all the States, the number of deaths per thousand members of the order having been 20.8. Georgia comes next in order, 13; then Virginia, 11.9; and the District of Columbia, 11.1. The rate of North Carolina was 10.9; Tennessee, 10.6; Maryland, 9.9; Missouri, 8.7; Pennsylvania, 8.6; New York, 8.5; Massachusetts, 8.1; Ohio, 7.8; New Jersey, 7.6; Michigan, 7.5; Indiana, 6.5; Illinois, 6.4; Wisconsin, 6; Rhode Island, 5.4; and Connecticut, 4.9.

The deaths from acute affections of the lungs were this year far in excess of those of previous years, a result undoubtedly due to the pneumonia following influenza. La grippe is charged with at least 87 of the 932 deaths. DR. SEAVERNS divides these deaths into three classes: 1, those occurring from the direct influence of the disease (47); 2, those in which previous disease was aggravated by influenza (20); 3, those in which the person succumbed to other disease for which la grippe prepared the way (20). The mortality was again the greatest in the Southern States. As to the deaths from phthisis, Rhode Island has the place of honor, not a death from this cause occurring among over 1000 members. Wisconsin and Indiana come next with a rate (from phthisis) of only 0.4 per thousand deaths; that of Pennsylvania, Massachusetts and Tennessee being about 1, while Virginia, North Carolina, Michigan and New Jersey have a rate of about 1.8 or 1 9. Notwithstanding the great caution in excluding doubtful risks, it is a somewhat sad commentary on medical prevision to learn that 54 out of the 932 deaths occurred within a year after the entrance examination had been passed. The report is full of interesting facts that we regret we may not recapitulate.

WEEKLY COST OF CARE OF THE INSANE IN AMERICAN ASYLUMS.

FROM the late report of the Committee on Lunacy of Pennsylvania we learn that the per capita weekly expense of maintenance in the principal State Hospitals was (1890) as follows: Harrisburg, $3.81; Danville, $3.31; Norristown, $3.61; Warren, $3.26; Dixmont, $4.31—the average being $3.66. This was for an average aggregate hospital population of 4879. In New York the average cost for 1907 insane in four hospitals was $5.09. In Michigan, three hospitals, 2382 patients, $3.84. In the Government Hospital at Washington, with 1475 inmates, the cost was $4.23. In Wisconsin, the cost was $3.76; in Indiana, $3.96; in Massachusetts, $3.60; in Connecticut, $3.20; in Minnesota, $3.15; in Ohio $3.39; and in Illinois, $2.95. The great lessening in the cost of maintenance is in some cases due to the self-supporting labor done by the chronic insane. It is a strange inhumanity that frequently, and indeed generally, supports thousands of idle people, when their labor rightly and judiciously applied would be a blessing to the one laborer who is supported and to the other outsider who is taxed for the supporting. Let the able ones be put to work.

PREDISPOSITION TO DISEASE IN THE NEGRO.

FROM an analysis of the diseases of 430,466 colored patients treated by the medical department of the Bureau of Refugees from 1865 to 1872, DR. REYBURN, late Surgeon U. S. Volunteers, makes some valuable comparisons as to the alleged predisposition of the African race to certain types of disease. Comparison is made with the diseases (22,053 cases) of white refugees. Among the negroes, there were 152,141 cases of remittent and intermittent fever, and the conclusion is reached that no difference in susceptibility to these fevers exists between the colored and the white people of the Southern States. In like manner the relative statistics disprove the statements commonly made concerning the extreme liability of the colored race to scrofula and pulmonary tuberculosis. The deaths from typhoid fever were 951, or nearly 25 per cent. of

the cases treated, the high mortality being dependent upon the intestinal lesions. The death-rate from diarrhœa and dysentery was also high, which DR. REYBURN ascribes to the ignorance of the colored people of the laws of hygiene and the use of improper articles of food. The colored freedman and the white refugee alike succumbed quickly to epidemic cholera. Under every variety of treatment about one-half of the patients died.

The remarkably small number of cases of delirium tremens among the negroes is charged by DR. REYBURN to "the want of development of the cerebral hemispheres." "Delirium tremens is preëminently a disease causing disorder of intellection, and hence the continued abuse of alcoholic drinks in the negro race is more apt to produce epileptiform convulsions or mania than delirium tremens."

The conclusion is reached that the negro race does not withstand the attacks of acute inflammation, such as pneumonia, nor do they recover from long-continued illnesses, such as typhoid fever, so well as the white race; but, on the other hand, the negro's power of repair after injuries and following surgical operations is believed to be superior to that of the white.

THE HEALTH OF COLLEGE STUDENTS.

FROM statistics kept at Amherst College during the last thirty years it is found that the percentage of illness among seniors has been nearly one-fourth less than among freshmen. It is also shown that from 1861 to 1865 the average yearly loss of time of the students from sickness was 2.18 days, while from 1885 to 1889 the average was about one-fifth less, or 1.75 days. In the first period the deaths were 6.1 per cent. of the number graduating, while from 1885 to 1890 the percentage was only 3.4. These interesting results are traced to the system of physical training and exercise introduced by DR. EDWARD HITCHCOCK, thirty years ago, as a part of the regular curriculum. If the data were to be had it would be an instructive study to compare these statistics with those of other colleges where systematic gymnastics is not compulsory, or where the systems are entirely different in character.

THE INFLUENCE OF SMOKING ON PHYSICAL DEVELOPMENT.

FROM the records of the senior classes of Yale College during the past eight years, the non-smokers are proved to have decidedly gained over the smokers in height, weight and lung-capacity. All candidates for the crews and other athletic sports were non-smokers. The non-smokers were 20 per cent. taller than the smokers, 25 per cent. heavier and had 66 per cent. more lung-capacity. In the graduating class of Amherst College of the present year, those not using tobacco have in weight gained 24 per cent. over those using tobacco, in height 37 per cent., in chest-girth 42 per cent., while they have a greater average lung-capacity by 8.36 cubic inches.

SOCIETY PROCEEDINGS.

THE GYNECOLOGICAL SOCIETY OF CHICAGO.

Meeting of February 20, 1891.

W. W. JAGGARD, M.D, IN THE CHAIR.

DR. HENRY T. BYFORD presented two specimens of fibroid tumors of the uterus removed by operation.

DR. E. C. DUDLEY reported a case of extra-uterine pregnancy which had extended five weeks beyond term and in which the fœtus was dead. Abdominal section, with the removal of the fœtus, was followed by recovery on the part of the mother. The adherent placenta was permitted to remain.

DR. J. H. ETHERIDGE reported two cases in each of which a multiloçular cyst of one ovary by pressure occasioned degenerative changes in the other.

DR. JOHN S. CLARK read a paper entitled

FIFTY YEARS' EXPERIENCE IN OBSTETRICS.

In his experience he had attended, in round numbers, 3500 cases of childbirth. He had never seen a woman die in actual labor and had never left undelivered a case to which he had been called.

During the first fourteen years of practice he had attended 700 cases without encountering a placenta prævia, an arm presentation, or eclampsia; two face presentations were the most troublesome complications. He could only recall three cases in which he had used the forceps. He had had but one death, thirty hours after labor, from uræmic poisoning.

In the next sixteen years he must have had 1500 cases. During this time he encountered his first arm presentation—a midwife's case, who had dallied with it all day—but kind Nature, as she most always does in preternatural presentations, had withheld hard pains, and the turning was easy and quite successful.

Of eight cases of placenta prævia which he had attended, in but two had he delivered living children.

He recalled seven cases of arm presentations; in all turning was easily performed, but the death-rate of the children was high; either three or four died.

In the following twenty years he attended more than 1300 cases, of which a disproportionate number was instrumental. He had never seen a woman die in childbirth. He did, however, have three deaths within twenty-four hours after labor—one at six hours, from exhaustion following a breech presentation; another in a case

of arm-presentation; and a third in a case of tedious labor in which the patient died twenty-four hours after delivery. All three were simply cases of exhaustion. These, together with the case of uræmic poisoning and four other cases—one of which was a most interesting case of pyæmia, in which death occurred thirty-five days after delivery, and that was worthy of a long and full report—are the only cases of death incident to gestation or delivery that he could recall in his whole experience.

Twice he felt compelled to practise perforation—once in a case of frontal presentation, when, for some cause, the forceps would not hold, and a second time in a case of vertex presentation, with the face in the hollow of the sacrum.

He could not recall a single death or a serious injury following a forceps delivery. He soon learned to make early applications, but always gave Nature a good chance.

He had been peculiarly fortunate in regard to hemorrhages after delivery, the life of the patient being endangered in but one case. But once in his entire experience was a patient seized with convulsions during, before, or after labor.

He had two cases of encephalic monsters.

He could recall having seen but two cases of spina bifida.

Earlier in his career he had used anæsthetics in labor much more frequently than now. He fails to see their value in most cases, and only uses them when from any cause the os is very tender and sensitive, or when about to perform a painful obstetrical operation.

He had used ergot quite frequently ever since he began to practise midwifery, at first only in inertia, viz., when pains were feeble; of late years for other purposes, principally for hemorrhages. In but a single case had he seen harm result from its use.

He had delivered a few times from above the superior strait.

It is astonishing how long a time, occasionally, will elapse, after the death of the fœtus, before it is cast off. Dr. Clark had a case in which three months elapsed between the death of the fœtus and its expulsion. In case of abortion hemorrhage is easily controlled by a well-fitting tampon; no harm results from its use. If the ovum has been retained for a long time and hemorrhages occur, an effort should be made to remove the ovum; for, the ovum once turned out, the bleeding ceases. He had known the ovum to be retained for twenty-eight days, and finally discharged with very little show, perfectly inodorous and unchanged. If decomposition takes place, the discharges offensive, the os open and the cavity of the womb easily reached, the ovum should be removed; but if the external os is tightly closed he would hesitate to invade the sanctuary on which Nature has written, "No admittance." Having seen a large number of cases of retained decomposing ova which came away or were absorbed without harm to the patient, he had little fear as to the result.

Address Wanted.—Will Dr. W. Clark, who sent a communication to THE MEDICAL NEWS, kindly send us his address?

CORRESPONDENCE.

CHANGES RELATIVE TO MEDICAL STUDENTS IN THE NORTHWESTERN UNIVERSITY.

To the Editor of THE MEDICAL NEWS,

SIR: Under the presidency of Henry Wade Rogers, LL.D., many changes are being made in the arrangement of work and in the management of the Northwestern University. Some of these are of enough interest to physicians to warrant the use of a little space in professional journals.

In the College of Literature a course has been arranged especially for those intending to study medicine. Since the spring catalogue was issued several changes have been made in this course and more are promised. It consists in a thorough course in organic and inorganic chemistry, mechanics, heat, sound, light, electricity, mathematics, German, French, psychology, logic, rhetoric, botany, biology, bacteriology, geology, zoölogy, and osteology. The biological work is in charge of Prof. Chas. B. Atwell, Ph.M., a graduate of Syracuse University. He is an enthusiastic student himself and he has the reputation of inspiring his scholars. He is spending his summer vacation with the German masters. His methods are such as to make the use of text-books secondary and incidental. This course is the result of a gradual evolution, but as a distinct course it was established last year.

From its foundation the Medical Department of the University has been known as the Chicago Medical College; the law school has been called the Union College of Law; the school of pharmacy has been the Illinois College of Pharmacy, etc. In the future these various titles will be dropped and the schools will be known simply as the Northwestern University Medical College, Dental College, School of Pharmacy and College of Law.

The Woman's Medical College has heretofore had an independent existence. Negotiations are now being completed to make this school also a department of the Northwestern University and to be known as the Northwestern University Woman's Medical College. It will remain as distinct from the old medical school as from the law school.

The courses in the medical schools have been lengthened to four years, but the preparatory course in the Literary College may apply as one year in the medical schools.

A University Council has been organized, consisting of the President of the University and the dean and one member of the faculty of each school. To this council are referred matters of mutual interest to the different colleges.

A fund of $150,000 is being raised to endow three chairs in the medical college. A new laboratory building is being erected in Chicago for the departments of medicine, pharmacy and dentistry.

A school of technology is not far distant in the future, since $150,000 has already been secured for that purpose.

For many years the school of medicine has encouraged its students to take a thorough preparatory course by

offering free lecture fees to those who have finished the studies of the freshman and sophomore years in the College of Literature, or the special course for medical students in the same college.

During the year fifty-two scholarships in the College of Literature have been established, corresponding with the number of State Senators in Illinois. To each State Senator is given the privilege of sending one student upon such scholarships.

Since a large proportion of the colleges of the University are in Chicago, it was ordered at the recent trustee meeting that the word "Evanston" be taken from the seal. In the future, in the place of independent commencements for the different schools there will be one commencement held, probably in the Auditorium, Chicago.

The Chicago Medical College was the first medical school in the country to adopt a graded course. In the past her classes have not been so large as those of some other schools, but the character of her work has been second to none, in the West at least. With the additional hospital advantages which the new Wesleyan Hospital will furnish, there is no reason why the Northwestern University Medical Colleges should not continue to do good work. Respectfully, H. B. H.

EVANSTON, ILL., JUNE 29, 1891.

CHICAGO.

DR. JOHN H. RAUCH'S resignation as Secretary of the State Board of Health of Illinois was tendered and accepted at the meeting of the board held in this city on June 30th. The letter of resignation was as follows:

W. A. HASKELL, M.D., President Illinois State Board of Health—Doctor: I beg to tender my resignation of the office of Secretary to which I was reëlected at the last meeting. While I must stipulate that this resignation shall take effect as of this date, I do not wish to embarrass the board in any manner and shall be happy to furnish the fullest information concerning the complicated details of the Secretary's office and to discharge without compensation any of its duties that the board may indicate for a reasonable period. Accept for yourself personally and convey to the other members of the board my thanks for the uniform courtesy and generous support which has been accorded me, since the first organization of the board in 1877, as your President and Secretary. Yours very truly,

JOHN H. RAUCH.

After reading the communication to the board, President Haskell said he presumed the members were sufficiently aware of the circumstances which had led Dr. Rauch to take this action. He would, therefore, refrain from any expression of opinion, but he desired to pay a tribute to the services which Dr. Rauch had rendered to the medical profession, to the cause of sanitary science, and to the lives of the citizens not only of Illinois, but also of the country at large, for nearly half a century. His name was known and honored on both sides of the Atlantic. Through his untiring energy, devotion to lofty ideals, and unhesitating self-sacrifice the board had come to be recognized as the most important factor in all questions of medical education, public sanitation, and the interests of the entire nation. He would not for the present express what he felt sure were the sentiments of his colleagues, but advised the board in accepting the resignation to appoint a committee to prepare an adequate expression of the high appreciation and esteem in which Dr. Rauch was held by the members and of their regret at his resignation.

A committee, consisting of Drs. Newton, Bateman, Clark and Ludlow, was then appointed, with instructions to publish its report before the next meeting of the board.

The quarterly report of the Secretary stated that the public health had been unusually good, contagious diseases having been rare.

It was decided to revoke all licenses of physicians convicted of malpractice. Charges having been brought against Dr. S. E. McCreary, of Peoria, for unprofessional and dishonest conduct, he was summoned to appear before the board to show cause why his certificate should not be revoked. He appeared by attorney, asked further time, and the case was postponed until the next meeting.

A petition was received from the Indiana Eclectic Medical College asking that their diplomas issued prior to May 15, 1890, be recognized. The petition was granted.

Dr. A. L. Clark was appointed to represent the board at the International Congress of Hygiene and Demography to be held in London next August.

NEWS ITEMS.

Washington State Board of Health.—The first Board of Health and Bureau of Vital Statistics in the new State of Washington, composed of five members appointed by the Governor in compliance with an Act of the Legislature approved March 7, 1891, was organized June 8, 1891.

The Cincinnati Lancet-Clinic.—The editorial chair of the Cincinnati *Lancet-Clinic*, made vacant by the transfer of Dr. Culbertson to the *Journal of the American Medical Association*, has been filled by the selection of Dr. A. B. Richardson—Dr. J. C. Oliver and Dr. L. S. Colter being associate editors.

The School of Medicine of the University of Texas —At a meeting of the Regents held last week at Austin, steps were taken to put the medical branch into operation next October. It was determined to arrange for eight chairs, with salaries affixed as follows: Three at $3000 each, viz., physiology, chemistry and surgery; four at $2500 each, viz., anatomy, materia medica, obstetrics and gynecology, and practice of medicine; one at $2000, viz., pathology and bacteriology. But two of the above were filled. Dr. H. A. West, of Galveston, was elected to fill the chair of Practice of Medicine; and Dr. J. F. Y. Paine, of Galveston, the chair of Obstetrics and Gynecology. The board also determined to have a three years' graded course, a session of seven months, and to require an entrance examination.

The medical branch of the University is located at Galveston. The State has nearly completed a handsome building at a cost of $70,000. Upon the block adjoining

is the Sealy Hospital, the gift to the State of Mrs. John Sealy. This hospital is a fine building. Its clinical material is controlled by the college faculty. Funds were appropriated for the equipment of the various laboratories. These facts are mentioned for the information of those who may seek the vacant chairs. An election to fill these vacancies will take place in Galveston the latter part of August next. For further information and details applicants may address Dr. Thos. D. Wooten, President of the Board of Regents, Austin, Texas; or Dr. T. C. Thompson, Galveston, Texas.

Ohio State Medical Society.—The Ohio State Medical Society held its forty-second annual session at Sandusky, June 18, 19 and 20, 1891. Dr. W. J. Conklin, of Dayton, presided, and Dr. G. A. Collamore, of Toledo, acted as Secretary.

The President read an address on Molière and the Doctors. Dr. H. J. Herrick, of Cleveland, read a paper on Carcinoma a Form of Perverted Nutrition. Dr. J. C. Reeve, of Dayton, read a paper upon the A. C. E. Mixture. Dr. A. R. Baker, of Cleveland, read a paper on Some Facts Every Practitioner Should Know About Squint.

Dr. G. A. Collamore, of Toledo, was elected President, and Dr. Fitzpatrick, of Cincinnati, Secretary for the ensuing year. The next meeting will be held at Cincinnati in May, 1892.

Congress of American Physicians and Surgeons.—The second triennial session of the Congress of American Physicians and Surgeons will be held at Washington, D. C., September 23, 24 and 25, 1891.

A number of distinguished foreign physicians and surgeons have accepted invitations to attend the session, among them Mr. Thomas Bryant, Mr. B. E. Broadhurst, Mr. A. E. Durham, Mr. Reginald Harrison, Surgeon-General W. E. McKennin, Mr. U. Pritchard, Mr. F. Treves, Sir William MacCormac, Dr. James G. Glover and Dr. William M. Ord, of London, England; Dr. McCall Anderson and Dr. W. T. Gairdner, of Glasgow; Mr. E. H. Bennett and Professor J. J. Cunningham, of Dublin; Professor John Chiene and Dr. J. Battey Tuke, of Edinburgh; Professor H. Krause and Dr. F. Beeby, of Berlin; Professor Curschmann, of Leipzig; Professor Hoffa, of Wurzburg; Professor Kühne, of Heidelberg; M. Emil Juval, M. E. Landolt and Dr. Pozzi, of Paris; Dr. A. Musso, of Turin; Dr. Von Mozengeil, of Bonn; Dr. Löwenber, of Paris; and Dr. Rafail Lavista, of Mexico.

The sessions of the Congress will be held in the Main Hall of the Grand Army Building, 1412 and 1414 Pennsylvania Avenue, from 3 to 6 P.M., daily.

The President's Address will be delivered in the Lecture Hall of the National Museum, Wednesday, September 23d, at 8 P.M.; it will be followed from 9.30 until 12 by the reception of the President. The Army Medical Museum will be open during the evening.

Medical Legislation in the State of Washington.—By an Act of the Legislature, approved April 10, 1890, the State of Washington has a Medical Examining Board, consisting of nine members, "learned and skilled in the practice and theory of medicine and surgery," appointed by the Governor for the terms of three years each. Examinations are held in January and July, alternately in the eastern and western parts of the State, and at such other times as may seem necessary. Applicants for licenses to practise are examined in anatomy, physiology, chemistry, materia medica, therapeutics, preventive medicine, practice of medicine, surgery, obstetrics, diseases of women and children, diseases of the nervous system, diseases of the eye and ear, medical jurisprudence and such other branches as the board shall deem advisable. The consent of five members is necessary for the granting of a license. The examination fee is $10. The board is empowered to refuse or revoke a license for unprofessional or dishonorable conduct, subject to the right of appeal. The words "unprofessional or dishonorable conduct" are used to mean: First, the procuring, or aiding or abetting in procuring, a criminal abortion; second, the employing of what are popularly known as "cappers" or "steerers;" third, the obtaining of any fee on the assurance that a manifestly incurable disease can be permanently cured; fourth, the wilful betrayal of a professional secret; fifth, all advertising of medical business in which untruthful and improbable statements are made; sixth, all advertising of any medicines or of any means whereby the monthly periods of women can be regulated, or the menses reëstablished if suppressed; seventh, conviction of any offence involving moral turpitude; eighth, habitual intemperance.

Infringement of the Act is punishable by a fine of from $50 to $100 and imprisonment of from ten to ninety days.

Indiana State Medical Society.—The forty-second annual session of the Indiana State Medical Society was held at Indianapolis, June 10th and 11th. The Alumni of the Medical College of Indiana celebrated the twenty-first anniversary of its organization by a banquet.

Dr. Theodore Potter presented an interesting report on Bacteriological Investigations. Dr. J. W. Milligan, of Indianapolis, read a paper on Antiseptic Methods Applied to Obstetrics. Dr. C. C. Morris, of Rockville, read a paper on The Salicylic Treatment of Typhoid Fever. Dr. J. A. Sutcliffe, of Indianapolis, presented an interesting paper on Perineal Section, with a number of illustrative cases. Following this Dr. C. H. Smith, of Lebanon, discussed the subject of Abortion. Dr. Owen read a paper on What Should be the Relation of Contract Corporation-Surgeons to the Medical Profession? The subject was referred to a committee consisting of Drs. Owen, Hibberd and Sutcliffe, with instruction to report before the close of the meeting. Dr. M. F. Porter, of Fort Wayne, read the Report of a Case of Sarcoma of the Ovary; Operation and Recovery. After this came a paper by Dr. F. C. Ferguson, of Indianapolis, on Some Fallacies in Gynecology. The subject of Diphtheria was treated by Dr. W. A. McCoy, of Madison. The venerable Dr. Lomax stated that he had encountered the term diphtherite in the beginning of his practice, fifty-four years ago, and the disease soon after; hence it was not, as sometimes supposed, a product of modern civilization. The address of the President, Dr. Gonzalva C. Smythe, of Greencastle, on The Influence of Heredity in Producing Disease and Degeneracy, and Its Remedies,

was an able one. Dr. A. B. Richardson, of Cincinnati, read a paper on Hysteria.

Dr. A. W. Brayton, of Indianapolis, presented a girl, fourteen years old, afflicted with the extremely rare disease of the skin known as xeroderma pigmentosum, or Kaposi's disease. This is the only case known to have been observed in the Mississippi Valley and the eleventh in the United States. Dr. G. W. McCuskey read a paper on Some Needed Medical Legislation. Following this came a paper by Dr. S. M. Voris, of Columbus, on Lacerations of the Perineum, and one by Dr. G. W. Vernon, of Indianapolis, on Vulvo-vaginitis in Children. Papers were read by Dr. F. C. Woodburn, of Indianapolis, on Valvular Heart Diseases; by Dr. S. C. Evans, of Union City, on Nasal and Naso-pharyngeal Reflexes; by Dr. H. McCullough, of Fort Wayne, on Functional Aphonia; by Dr. C. L. Thomas, of Logansport, on Cataract, With or Without Iridectomy; by Dr. Norman Teal, of Kendallville, on Health and Vital Statistics; by Dr. S. W. Gould, of Argos, on Opium and its Preparations; by Dr. M. F. Johnston, of Richmond, on Angina Pectoris.

The following officers were elected for the ensuing year: President, Dr. Edwin Walker, of Evansville; Vice-President, Dr. Erwin Wright, of Huntingdon; Secretary, Dr. I. I. Elder, of Indianapolis; Assistant Secretary, Dr. T. A. Kennedy, of Shelbyville; Treasurer, Dr. J. O. Stiltson, of Indianapolis. The next meeting will be held on the second Thursday of May, 1892.

Sir Prescott Hewitt, the distinguished English surgeon, died recently aged seventy-seven years.

Scanzoni, the distinguished obstetrician and gynecologist, died recently aged seventy years. He succeeded Kievisch as professor of obstetrics at Würzburg, a position that he occupied for thirty-seven years. He was the author of numerous important works in obstetrics and gynecology.

The Mitchell District Medical Society will hold its annual meeting at West Baden Springs, Indiana, July 16 and 17, 1891. A long list of scientific papers will be presented. Dr. A. M. Owens, of Evansville, is the president; Dr. H. W. Shirley, of Shoals, the vice-president; and Dr. George W. Burton, of Mitchell, the secretary of the Society.

Work of the U. S. Army and Navy Medical Examining Boards.—Through the courtesy of the Surgeon-Generals of the Army and Navy I am able to give you the following results of the work of their Examining Boards for the last ten years:

Before the Army Boards 384 candidates presented themselves during this period, of whom 76, or 22.3 per cent., were approved and passed, 31 were rejected for physical disqualifications, 90 failed to pass the preliminary examination and the remainder failed to pass the medical examination. The rejections for physical defects are for the last three years only.

Before the Navy Boards 237 candidates presented themselves, of whom 55, or 23.1 per cent., were approved and passed, 75 were rejected for physical disqualifications, and the remainder either withdrew or failed to pass.

Evidently the standards of the two boards are about the same. The proportion of those rejected for physical defects is noteworthy. In a general way we may say that about one-fourth of the candidates before such boards are approved, and one-fourth fail on the preliminary examination as to general education. Putting aside those rejected for physical causes, and making the necessary corrections for a certain number who came before the boards more than once, we find that of 429 examined, 129, or 30.2 per cent., were successful.

Of those candidates who had a college degree 34 per cent. succeeded, and of those who had no such degree, 28.9 succeeded. Of those candidates who had had one year's residence in a hospital, 40 per cent. passed, while of those who had not been residents, only 21 per cent. were successful. The percentage of successful candidates from different schools varies greatly, ranging from 9 to 56 per cent. for those schools from which more than ten candidates presented themselves. I cannot go into details on this point, but may say that taking the Medical Schools of Harvard, Yale, the College of Physicians, and Bellevue Hospital of New York, the University of Pennsylvania, and the University of Virginia, together, of 141 candidates, 65, or 46.1 per cent., succeeded, while for all the rest of the schools in a body, of 586 candidates, 64, or 22.3 per cent., succeeded.—DR. JOHN S. BILLINGS.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 30 TO JULY 6, 1891.

BUELL, JAMES W., *Assistant Surgeon.*—Is retired from active service, by reason of disability incident to the service.

OWEN, WILLIAM S., JR., *Assistant Surgeon.*—Is detailed to attend the encampment of the Illinois National Guard, near Springfield, Ill., from July 18th to 25th, and August 11 to 18, 1891.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING JUNE 27, 1891.

HAMILTON, J. B., *Surgeon.*—Ordered to Washington, D. C., on special duty, June 9, 1891.

GEDDINGS, H. D., *Assistant Surgeon.*—Ordered to New York, N. Y., on special duty, June 13, 1891. Ordered to Washington, D. C., on special duty, June 26, 1891.

WERTENBAKER, C. P., *Assistant Surgeon.*—When relieved at Galveston, Texas, to proceed to Chicago, Ill., for duty, June 23, 1891.

SMITH, A. C., *Assistant Surgeon.*—Relieved from duty at New Orleans, La.; ordered to Galveston, Texas, June 23, 1891.

STIMPSON, W. G., *Assistant Surgeon.*—Ordered to New York, N. Y., for temporary duty, June 12, 1891.

ROSENAU, M. J., *Assistant Surgeon.*—When relieved at Chicago, Ill., to proceed to New Orleans, La., for duty, June 23, 1891.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

ORIGINAL ARTICLES.

PHILOSOPHY AND HOMŒOPATHY.

BY SOLOMON SOLIS-COHEN, M.D.,
PROFESSOR OF CLINICAL MEDICINE AND APPLIED THERAPEUTICS, PHILADELPHIA POLYCLINIC; PHYSICIAN TO THE PHILADELPHIA HOSPITAL, ETC.

IN a volume of essays[1] submitted by the Editor of THE MEDICAL NEWS to the writer for review, the professor of materia medica and therapeutics in the Homœopathic Medical College of the University of Michigan has endeavored, among other things, logically to establish upon *à priori* grounds the validity of the so-called "homœopathic law of cure." The author seems to be a thoughtful writer, and his essays have the merit of perspicuity, so far as the essentially imperspicuous nature of his case allows. He is evidently firmly convinced that truth is with him. He frankly confesses wherein the practice of the so-called homœopathist of to-day departs from the principles laid down by Hahnemann. His tone is temperate and his style is scholarly.

For these reasons a more extended examination of a few of the arguments and illustrations brought forward in this series of papers than would fall within the limits of the ordinary book-notice, will not be unprofitable.

The subject of what is and what is not homœopathy might perhaps be left to the followers of Hahnemann, true and false, as a matter of no concern to those whose time and thought are devoted to the investigation of the problems of the causes and processes of disease, and the discovery of means wherewith to promote or restore health. Unfortunately, however, opponents of legislation which shall debar the unscrupulous and incompetent from disgracing the ranks of the medical profession, have brought the status of homœopathy prominently forward as a disturbing element.[2]

In discussions thus provoked, so many reckless assertions have been made by apologists for homœopathy, both in its own ranks and in the ranks of the profession of medicine, that a candid and straightforward statement, such as is made by Professor Mack, becomes of inestimable value in clearing the ground of discussion from a tangled overgrowth of false issues. In an essay read before the Philadelphia County Medical Society the writer of this review offered certain propositions concerning the nature and scope of homœopathy, which have been vigorously denied by homœopathic critics; one of whom went so far as to bring a charge of misquotation, but without making any attempt to substantiate that charge. In the logical papers of Prof. Mack, we find exactly the same views of homœopathy as those set forth in the paper referred to.[1]

The writer's propositions were as follows:

1. Homœopathy is exclusively a system of drug-therapeutics.

2. It is an exclusive system, arbitrarily devised, inflexible and claiming infallibility.

3. It expressly prohibits the endeavor to interpret morbid symptoms as indications of changes in the structure or functional activity of definite tissues and organs . . . and fixes attention upon the symptoms alone, independently of their origin, as constituting the whole of the disease and affording the sole indication for treatment.

4. The doctrine of homœopathia is inextricably bound up with the practice of infinitesimal dosage.

Concerning the subject-matter of the fourth proposition, Prof. Mack has nothing to say; indeed, he expressly avoids the question; so that it may be left out of consideration in the present paper.

Let us see, however, what he has to say concerning our first proposition, that *homœopathy is exclusively a system of drug-therapeutics*. In an essay

[1] Philosophy of Homœopathy. Charles S. Mack, M.D. 8vo., pp. 174. Chicago: Gross & Dellbridge, 1890.

[2] The writer, in common with those physicians of Pennsylvania who have supported the proposed bill to create the "Board of Medical Examiners and Licensers," would heartily favor any honorable means whereby the best men in the homœopathic ranks could be united with the best men in the ranks of the so-called "regular" physicians in furtherance of this wholesome legislation. Our aim is to protect the community from charlatans and pretenders, "regular" or "irregular," and not to war against theories or methods of practice. These latter are proper subjects for discussion, but not for legislation. State examinations could be held in the fundamental sciences, and not upon the arts of medicine; upon anatomy (normal and morbid), physiology, chemistry, toxicology and certain admitted principles of hygiene, surgery, and obstetrics, but not upon therapeutics or the practice of medicine. Thus the entire question of "schools" or "sects" could be avoided without injustice on the one hand or compromise of principle upon the other.

[1] Proceedings of the Philadelphia County Medical Society, vol. ix. p. 278 et seq.; THE MEDICAL NEWS, Oct. 19, 1889, p. 427 et seq.

entitled "Homœopathy: the Only System of Curative Medicine," the author draws a distinction between *cure* of patients and their *recovery*, and a parallel distinction between *homœopathic treatment* and *useful non-homœopathic treatment*. He distinctly states that measures of prophylaxis and of palliation, hygienic measures and the administration of antidotes, of parasiticides, etc., are *not homœopathic*, though they may lead to the recovery of the patient.

A patient who has recovered after the cause of his disease has been removed, is not, however, cured. Cure of a patient, according to our author, is something entirely apart from the use or effect of remedial measures having reference either to the cause of the disease or to the pathological processes, structural or functional, resulting from the operation of that cause. "By *cure*," he says, "we mean such modification of the quality of vital processes and their effects that whereas these processes and effects were abnormal they shall become normal, and this as the *direct* result (not an indirect) of the medicine used. A drug can be curative only by reason of its dynamic effects upon the patient. Curative treatment is invariably a treatment of the *patient*, and never a direct attack upon the cause of disease." Again, he says: "We have recognized the propriety of avoiding proximate causes of disease; to avoid them is hygienic. We have also recognized the propriety of directly attacking, and destroying, and removing such causes when they exist upon or in the body, by any means not harmful to the patient; this is prophylactic. These hygienic and prophylactic measures are *aside from the subject of homœopathy*, and, as we have seen, are not curative." And again: "The two sets of facts between which a law of cure must define the relation are, on the one hand, unmodified disease-effects, subjective or objective; and, on the other hand, unmodified dynamic drug-effects, subjective or objective." And again: "We may say, moreover, that curative treatment is invariably the treatment of a patient with a drug (or drugs) indicated by the symptoms which he exhibits."

These citations clearly exhibit many things, to some of which we may return hereafter. For the present it will be sufficient to note the claim that homœopathic treatment and curative treatment are identical; and the explicit statements (*a*) that treatment directed against the causes of disease is not curative, and therefore *not homœopathic*, and (*b*) that the *only curative* or homœopathic treatment is the giving of "*a drug or drugs* indicated by the *symptoms* of the patient." This claim and these statements entirely bear out our first proposition, and partially bear out our second and third propositions.

In another essay entitled, "Is Homœopathy Exclusive?"—which may be considered in connection with our second proposition (*i. e.*, that homœopathy *is* exclusive)—the author affirms his willingness to help his patient to recover by "useful, non-curative treatment," but again distinctly asserts that such treatment is not homœopathic. "The explanation of any apparent inconsistency here," he says, "would be arrived at by accurately defining the word *cure*. Having thus defined *cure* we should, I think, be in a position to maintain that no treatment not homœopathic can be curative—*that, as a system of curative medicine, homœopathy is exclusive;* but it does not follow that there may not be indefinitely many principles (concerning which *similia* says nothing) upon which useful, though not curative treatment, can be based." Again, he says: "We have now, by exclusion, demonstrated that *no possible law of cure can exist* excepting that which defines *similarity between unmodified disease-effects and unmodified dynamic drug-effects* as the criterion by which we can know that a drug is curative. We are thus obliged either to fix our belief in *similia* as the law, and *the only possible law of cure*, or, as regards curative medicine, to take up with that most dismal belief which has come to be known as medical nihilism."

Surely no stronger statement of the claims of homœopathy as an exclusive system could be made. And, again, it will be noticed that drug-giving is not only tacitly assumed, but is expressly stated as the one method of homœopathic treatment—the only method of cure.

Let us now consider some of Prof. Mack's statements in relation with our third proposition, concerning the ends sought to be achieved by drug-giving in accordance with the homœopathic principle. We have already seen that homœopathic treatment, as such, does not aim at the removal of the causes of disease. This, our author states, is prophylaxis and not cure; while homœopathy has only to do with cure. It does not aim to combat the effects of pathological processes, or to antidote poisons, or to remove from the blood toxic products, the result of disease. These measures, says Prof. Mack, as plainly as language can say anything, may be useful; they permit the patient to recover; but to permit a patient to recover, or to be useful, is not the object of homœopathy.

Thus, the administration of stimulants to carry a patient over some critical period is useful but not curative, and therefore it is not homœopathic (p. 37). And here is an illustration which we cannot do better than to quote exactly in the words of the candid writer. In speaking of the use of atropine to avert the danger of adhesion between the iris and the lens in cases of inflammation of either of these structures, he says: "This certainly is not homœopathic, equally certainly it is

not curative; to modify in any way the inflammatory process is not the direct object of such treatment; the object of such treatment is simply prophylactic." Again, he says: "Never admit into either of those two distinct sets of phenomena (disease-effects and drug-effects) between which you institute a comparison in your search for a curative medicine—never admit into either of these sets of phenomena an hypothesis as to how a particular effect has been produced." The full significance of this extraordinary teaching must be reserved for discussion further on. For the present it is enough to note that it bears out the proposition that homœopathy forbids the attempt to produce by our remedial measures definite effects upon definite structures or functions. This is still more evident when we read again: "If B is cured of syphilis by the use of mercury it is not because A was cured of syphilis by the use of that drug. Each is cured because mercury is capable of producing effects similar to those produced by syphilis in him." Given a patient, then, with syphilis and without symptoms similar to those occasioned by the use of mercury, he could not be homœopathically treated with mercury; or given a patient with syphilis, and without symptoms similar to those produced by the use of potassium iodide, he could not be homœopathically treated with the latter drug; because homœopathic treatment is not directed against the cause of the disease, or against pathological processes or their effects, but is solely based upon symptoms manifested in the individual patient, without reference either to the cause of the symptoms or to the pathological conditions which they denote.

Such being Professor Mack's exposition of homœopathy, we wonderingly ask how a thoughtful man can put his faith in such a system, and even come before the world as its champion on the ground of its philosophic truth. The answer must be found in that tendency to mysticism which is often associated with the highest qualities of intellect. From some allusions in the medical essays, and from other essays found in the same volume, we judge that the author is a member of a certain sect of mystics. It would be grossly improper, of course, to discuss or debate his faith—and we ignore altogether in our critique of his position some remarkable theories of analogy between disease and sin, homœopathy and confession, and so forth—but we may evidence these matters as an illustration of the psychological tendencies leading to what we consider his fundamental error in the conception of life and its processes. He assumes that vital activities and their perversions are not to be considered in relation with the general laws of energy; but that a mysterious something to which he gives no definite name, but which, for all intents and purposes, is the same as the "vital principle" of the ancients, is the governing power in such processes. Thus, disease becomes to him, as to Hahnemann, a derangement of this immaterial vital principle, and not a disturbance of function or alteration of structure in the material body. Thus, to him, as to Hahnemann, the causes of disease are essentially unknowable, and treatment directed against those causes unphilosophic. This position naturally leads our author, as it led Hahnemann, into some direct contradictions, as will be seen from the remarks upon "useful treatment" and "proximate causes," which we have quoted; but he evades the full force of this contradiction by his candid admission that "useful prophylactic treatment"—under which head he includes all measures directed against morbific agents or agencies—is not homœopathic.

The ethical question here involved, to our mind of highest importance, the author entirely overlooks. Patients consult a physician in order to be restored to health as quickly and as completely as possible. As a rule, they have no knowledge of medical history or of medical doctrines; and rarely are they acquainted with even the elements of the sciences upon which medical practice is based. They go to this man or that woman because of reputation, or because of supposed adherence to a certain "school;" but they draw no distinction between "cure" and "recovery," between "useful" and "curative" treatment. When one recovers, he says he has been cured; and he attributes the alleged cure to homœopathy, if the practitioner in attendance is professedly a homœopathist. Yet that practitioner, as shown by Professor Mack, may not have treated the patient homœopathically in any particular. To undeceive the patient, saying "You have not been cured, but have recovered; and your recovery is not the result of homœopathic treatment, but of useful treatment," would be eminently honest—but it is an unheard-of event. On the other hand, is it not dishonest to allow the patient to imagine himself "cured" by homœopathy, when in reality he has recovered under useful, *i. e.*, sensible, treatment? Professor Mack has himself laid the foundation for this question. It must be answered, and it can have but one answer.

This, however, is a digression. There is still another most unphilosophical doctrine affirmed in the name of philosophy in the essays under review, which demands attention. It is logically the only basis upon which homœopathy can rest. That it is an insecure basis will be self-evident. The author elaborately affirms that experience weighs neither in favor of nor against the fundamental principle of homœopathy, *similia similibus curantur*. That principle is held to be proved "by exclusion" to be the "only possible law of cure," and if theory

does not agree with facts, "so much the worse for facts."

True, this most astounding teaching is nowhere set forth in so many words as a terse and citable proposition; but it permeates the book. The author avowedly sets out to discover by *à priori* reasoning a "law of cure;" his reasoning is professedly abstract throughout, and nowhere in his studies does he appeal to the lessons of experience for confirmation of his assertions. Moreover he says, apparently unconscious of the contradictions involved: "Statistics regarding results in homœopathic practice may afford *evidence* of the truth of *similia*, but should never constitute our *reason* for the choice of a remedy as homœopathic in a case under treatment. The *reason* for this choice should always be that the medicine chosen is capable of producing unmodified dynamic effects similar to the disease-effects manifested in our patient." What kind of "reason" that may be, which is independent of evidence, we cannot imagine. Again we read: "To base practice simply on evidence is empiricism." In other words, the results of treatment are to have no bearing upon the selection of remedies.

Still more plainly is this strange doctrine found in the following: "History says that Hahnemann's first suspicion that *similia* is the law of cure was an induction from the premises—that cinchona cures malarial patients, and that the effects producible by cinchona are similar to those producible by malaria. *It need not shake our belief in homœopathy to discredit these premises.*" Indeed, one cannot attentively read the various essays in this volume without becoming convinced that the author would believe in and teach homœopathy—we do not say practise it—though he had never thought that he had cured a patient by it; though he had never heard of anyone else having done so. He would say: "The law is true, our application of it defective."

Professor Mack, we believe, fails to grasp the meaning of the term "law" as applied to the processes of nature. A law (fundamental principle) of nature, as expressed by men, is simply a terse generalization—an induction—founded upon a multitude of observed facts. It is the briefest expression which will include a certain group of relations learned by experience. It has nothing in common with the law (statute) which is made by parliaments, autocrats, or mobs. A law of men may be disobeyed; may fall into desuetude; may be repealed. A law of nature is not related with the possibility of neglect or disobedience; and, flowing as it does from the eternal constitution of things, is eternal as the Maker of all things.

The only means by which man can arrive at a knowledge of natural laws is by observing their operations. It was by such observation that Newton was led to the profound generalization which we know as the "law of gravitation." He tested the truth of his hypothesis by comparing it with the facts of experience; and it was not until the revised measurement of the terrestrial meridian had enabled him to revise his calculations and prove the correspondence of fact with theory, that this true philosopher announced to the world that the falling moon obeyed the same law as the falling apple.

But small need be our wonder that our author decries observation and experience. Observation and experience, continually accumulating, show the fallacy of homœopathy, even as an occasional empirical guide in practice, to say nothing of its claim to be a universal and exclusive system of cure. Though Professor Mack says it is "without flaw," he himself demonstrates its inadequacy in the confession that it must be supplemented with prophylactic, palliative, antidotal, and other useful measures. Though he lauds it as the only reasonable system, he himself exposes its foundation upon unreason in the warning to students not to attempt to discover in their investigation of the powers of therapeutic agents "how a particular effect is produced."

That the intellect often forges for itself heavy fetters of theory is well known; and yet one is tempted to inquire why an author, who so clearly shows that *useful treatment is not homœopathic*, did not go one step further, and learn that *homœopathic treatment is not useful.*

WHAT TO DO FOR INCIPIENT CATARACT.[1]

BY EDWARD JACKSON, M.D.,

PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC; SURGEON TO WILLS EYE HOSPITAL, ETC.

I CLOSED a paper on the "Diagnosis of Incipient Cataract," read before this Society in 1885 and published in the *Transactions* of that year, with these words: "Many interesting questions arise with reference to the etiology, prognosis, and management of growing cataract. But their profitable consideration and elucidation wait upon accurate and complete diagnosis—diagnosis in the broad philosophical sense, that rests not on naming a morbid condition present, but which, through due consideration of all possible pathological factors, traces the connection of symptoms to their cause." The present paper is in direct continuance of the line of thought then taken up.

The first thing to be done in any case of cataract is to complete the diagnosis by a careful study of all the evidences of departure from ocular or general health; for "it may be assumed, as a rule, that

[1] Read before the Medical Society of the State of Pennsylvania, June 4, 1891.

when the lens, by its opacity, gives evidence of impaired nutrition, it does not suffer alone. And that when cataract is noticed, instead of accepting it as the cause and explanation of all existing symptoms, we should be aroused to new diligence in the search for deeper and probably more important lesions." Not only are concomitant lesions to be sought or excluded, but I believe that we are now in position to learn something, perhaps much, with reference to the causation of cataract; such knowledge will enable us to render our patients material benefit in preventing the occurrence or advance of the condition, and in certain forms of opacity we may even be able to secure some improvement in the transparency of the lens.

From habitually speaking of certain forms of cataract as "senile," we have come too commonly to regard them as simply a result of the necessary and unavoidable change brought about by age, in the same sense that the loss of accommodation or the whitening of the hair is a senile change. Such a view, however, is not in accordance with the facts. Cataract is not confined or nearly confined to the oldest persons. While I am not prepared to give statistics on the subject, my impression is that opacity of the lens commences no more frequently and progresses less rapidly after the age of sixty than between the ages of forty-five and sixty. Moreover, a large proportion, probably a majority, of those who live to extreme old age, remains free from any opacity whatever of the crystalline lens. Even when cataract develops, it is usually not regularly progressive; in a very large number of cases it becomes stationary and remains so throughout life. Many such cases have been reported. In the *Royal London Ophthalmic Hospital Reports* for 1867 is recorded one that is of especial interest, because a drawing of the original condition had been made by William Bowman, and after eighteen years there was no material change in the degree of opacity. I well remember a case, seen in the service of Dr. George C. Harlan, in which we agreed that the appearance of the opacity indicated its probably rapid increase. The patient received this opinion very quietly, and explained her complacency by stating that she had been told the same thing six years before, while her sight had not grown worse since then. Of ten patients seen by me over ten years ago, whose histories I have been able to follow to the present time or until the death of the patient, in but one has the lens been extracted, and in but one other was there a mature cataract. Six died with cataracts still immature and two are still living, or were a few months ago, without any very great increase in the degree of opacity of the lens. The fact that in comparatively few of the eyes that present incipient cataract a condition is reached requiring extraction of the lens emphasizes the importance of our present subject, and seems to indicate that cataract is a senile condition in much the same sense as apoplexy or chronic interstitial nephritis.

The complete diagnosis of a case of incipient cataract usually reveals a certain degree of ametropia that in general should be corrected. I remember a case, sent to me over five years ago, supposed to be nearly blind and ready for early operation, in which the correction of the hyperopia gave vision of $\frac{15}{20}$ths in one eye and $\frac{15}{15}$ths in the other; the vision is still sufficient for all the ordinary demands of life. Hyperopia is the most common local defect in these cases. Very often it is combined with astigmatism, and at the age at which cataract most commonly occurs we frequently encounter cases with high degrees of regular astigmatism that deviate from the rule in that the meridian of greatest refraction is at or near the horizontal instead of the vertical. Such cases may readily be overlooked or be regarded as cases of irregular astigmatism. Myopia, allowing the patient to see near objects without the use of glasses, the so-called second sight of old persons, is also often a precursor or accompaniment of opacity of the lens. Whatever the form of ametropia, the improvement of vision obtained by its correction is quite as important to the patient, and is quite as likely to be appreciated by him as the same, or even a somewhat greater, degree of improvement wrought by operation.

It is uncertain in what degree accommodative strain is a direct cause of opacity of the lens, but it is probably causative to a considerable degree. Certainly in many cases opacities of the lens first appear at the age when accommodative strain from advancing presbyopia is at its height, and becomes stationary when the strain is removed, either by glasses, by discontinuance of the effort of using the eyes, or by complete loss of the power of accommodation. If in such cases the opacity be not primarily due to the eye-strain, it certainly is made worse by the strain.

We have yet much to learn about the etiology and treatment of cataract. Our ideas are far from clear, but amid the haze there stands out clearly the fact of the relation between choroidal disease and cataract. It has long been known that myopic eyes presenting serious choroidal changes are especially liable to cataract. It is also generally recognized that certain occupations, especially glass-blowing, strongly predispose to both cataract and choroiditis. I have noted that blacksmiths and others who work with heated metal, and professional cooks, exhibit this especial liability. In a large majority of cases of incipient cataract the opacity appears first and is most advanced in the lower quadrants of the lens, particularly the inner or nasal quadrant. The only

rational explanation of this that I know of is that these quadrants of the lens depend for their nutrition principally on the adjoining portions of the choroid, which are the portions most exposed to the glare of light and heat from above, and are therefore most liable to and most deeply involved in chronic choroidal inflammations.

Many surgeons, too, have noted the frequency with which the ophthalmoscope reveals choroidal changes when the opaque lens has been extracted, or rather the extreme rarity of the absence of such changes; but it is only recently that a fellow-member, Dr. S. D. Risley, in the *University Medical Magazine* for March, 1889, and again in a paper read at the recent meeting of the American Medical Association, has completed the demonstration of the connection between choroiditis and cataract by extensive and careful clinical study of the subject, including a series of cases of incipient cataract, in 70 per cent. of which one or both eyes presented demonstrable disease of the choroid.

It has long been recognized that the vitreous body and the crystalline lens are equally dependent on the uveal tract for their supply of nutrient fluid, and the connection between choroidal disease and vitreous opacities has been clearly recognized. It seems strange that more importance has not been attached to the relations of such disease to opacities of the lens. It cannot be doubted that the failure to recognize such a relation has in practice led to neglect of patients with cataract. No one would tell a patient with commencing or recently acquired vitreous opacity that nothing could be done for it, unless in the course of time it became so dense as to justify a resort to an operation, and then that tearing it asunder might partially restore sight. We treat such opacities mainly through the choroiditis that accompanies them, often with improvement and sometimes with complete restoration of vision. The treatment of opacities of the lens cannot lead to a similar restoration of that part to its original integrity, for we have to deal with a structure practically composed of non-living epithelial substance, instead of a connective tissue; but such treatment may in the one case be just as efficient in preventing further advance of the opacity as it is in the other. There are a few cases of diffuse clouding of the lens that I am satisfied, under appropriate treatment, clear up in quite an appreciable degree. Certainly no patient with cataract has justice done him until evidence of choroidal disease has been carefully sought, and if discovered met by treatment.

The treatment of choroidal disease, particularly the chronic inflammations, is too extensive a subject to take up in detail here, but these are its principal general features: 1. The relief of eye-strain by the correction of errors of refraction; making good deficiencies of accommodation by means of the proper glasses, and strict moderation in the use of the eyes. 2. Avoidance of excessive exposure to light and heat, whether the excess be in the intensity of the light or in the length of the exposure; this may involve change of occupation for the cook, the blacksmith, or the fisherman, as well as the employment of dark glasses and of other more usual precautions. 3. Attention to the extra-ocular conditions pertaining to the general nutrition, for these powerfully influence the structural and functional perfection of the nutritive coat of the eye.

This last field, with joint investigations carried on by the ophthalmic specialist and the general practitioner in close association, promises much. Few general practioners, perhaps, would be able to observe and record the minute changes that mark the course of choroidal disease in a progressive, a stationary, or a regressive,[1] incipient cataract; while no one but the regular medical attendant could steadily follow the course of the general health and systematically carry out a line of treatment. That opacity of the lens does, as a rule, appear and progress mainly during periods of impaired general nutrition, and that there is a tendency to an arrest of its progress with improvement in the general health, may be regarded as certain in a large number of cases.

From time to time it is claimed that cataract has been cured without operation. The popular application of the term cataract, however, is so loose and indefinite, and the improvable or curable diseases that may be associated with opacity of the lens are so numerous, that one who understands the subject and is acquainted with the history of past errors in this direction is always tempted to summarily dismiss all such claims.

One of these alleged remedies that in various forms has repeatedly been put forward is manipulation of the globe. It is worth referring to now, because Dr. R. Kalish, of New York, has recently narrated some cures of cataract by a form of manipulation, conjoined with the instillation of a solution of boric acid in rose-water and glycerin, and with general medication. Dr. Kalish's reports[2] of his cases seem too rosy; they do not give sufficient evidence that the phenomena have been subjected to the searching white light of scientific scepticism; they remind

[1] Let this use of the word regressive not be misunderstood. It is not meant to imply that any considerable number of opacities of the lens diminish in degree or that any entirely disappear. So far as I know it is only strictly applicable to the few cases of diffuse clouding of the lens already referred to, and to these for comparatively brief periods of their duration. I hope that it may become more widely applicable to these, but at present the most we can expect for any considerable number of cases of incipient cataract is that they will become stationary.

[2] Medical Record, March 29 and December 30, 1890.

one of a recent paper read before a homœopathic society narrating five cases—one in the person of an "allopathic physician"—in which great improvement took place after the use of "iodoform 3x." Still, in this connection it is worth while to note that Mr. J. T. Thompson, of Cardiff, England, has reported[1] a case in which, after a Foerster's operation for the artificial maturation of cataract by iridectomy and the stroking of the lens through the cornea, the vision was first reduced to counting fingers at three or four feet, and then improved, with actual clearing up of the opacity of the lens, until the patient, depending on this eye, was able to read moderate-sized print and to do her housework. It is probable that manipulation may influence the nutrition of the lens, and it is quite possible that it may cause diminution of a certain form of opacity of the lens. The subject is probably worthy of further investigation.

The dilatation of the pupil by the use of a weak mydriatic solution when the opacity is confined to the centre of the lens, is a measure that has long been recommended in our text-books. It is of service in a few cases. In a greater number of cases in which the periphery of the pupil is involved, and especially when the change in the lens has given rise to irregular astigmatism without much actual opacity, a condition that may continue for years, considerable relief may be afforded by causing contraction of the pupil by means of a weak solution of eserine or pilocarpine.

Even if all treatment fails to arrest the progress of the opacity of the lens and useful vision is lost, it is not, as formerly thought, needful to wait until the whole of the tissue of the lens becomes opaque before proceeding to extraction. Aside from Foerster's operation for hastening maturation, the extraction of immature cataracts is not so difficult and uncertain as it was formerly supposed to be. Peripheral capsulotomy and the washing out of clear cortex by some such method as that advocated by Dr. Lippincott at our last meeting, reduce the extra risks of such extraction until they are very slight.

In the present state of ophthalmic surgery, instead of saying to a patient, "You have cataract; nothing can be done for it now; you must wait till it ripens and undergo an operation; then, perhaps, with strong lenses you will be able to see again;" it is nearer the truth and a better performance of professional duty to say, "You have a commencing opacity of the crystalline lens; it is essential that you take good care of your eyes, using them moderately and with the proper correcting lenses; you must pay careful attention to your general health and have the proper treatment for diseased conditions that may be causing this opacity. If you are able and willing to attend to these things the probability is that you can preserve your sight for a long time, perhaps throughout life; and even if this is not granted, you will be placed in the most favorable condition for the restoration of vision by a comparatively safe and painless operation as soon as your vision has failed so far as to be no longer useful."

PNEUMO-THERAPEUTICS.[1]

BY DR. HOVENT,
OF BRUSSELS.

BATHS of compressed or rarefied air are given by means of seven iron chambers of varying capacity, some being capable of comfortably containing from two to ten persons. Each chamber is well constructed; it is supplied with several windows of glass two centimetres (three-quarters inch) thick; it has a duplicated door, or perhaps better expressed, two doors enclosing a lobby, in which the doctor, entering by the outer door, can shut himself, and then equalizing the pressure, can open the inner door and speedily reach the patient for any purpose, without great alteration of the pressure in the chamber. Another smaller door, also duplicated, serves for the purpose of handing to the patient books or whatever may be desired. Electric-bell, elbow-chairs, toilet-tables, manometer, thermometer, hygrometer, etc., are all at hand.

From the chamber so described emerge six pipes, leading to the underground tanks of 1, compressed; 2, rarefied air; 3, nitrogen; 4, oxygen gas; the remaining two pipes are for the purpose of purifying the air. Each of the first four pipes is attached to a little tank which permits of the measurement of the quantity of air, nitrogen or oxygen introduced into the chamber, or of the quantity of air removed.

The large tanks in which the air or gas is compressed, or rarefied, are ten in number. Each holds several thousands of litres. The compression or the rarefaction of air or gas is obtained by means of a gas-engine of eight-horse power. The tanks will bear seven or more atmospheres of pressure, or a corresponding degree of rarefaction.

The manipulations are as follows: If it is desired to place the patient in a chamber, and the pipe connecting the chamber with the tank of compressed air, for instance, is opened, this compressed air rushes in; its quantity can be regulated according to circumstances. The reverse takes place if rarefied air is to be used; the air of the chamber rushes out, and the patient remains in a relative vacuum.

One serious and even capital drawback to the

[1] Abstract of a communication to the Philadelphia County Medical Society.

employment of air-baths lies in the fact that in the course of the two hours, the duration of an ordinary sitting, the air within the cabinet soon becomes foul from the processes of respiration, perspiration, etc. The establishment at Brussels is the only one in which this inconvenience is efficaciously overcome. The air is being constantly withdrawn from the occupied chamber, and purified by being passed through several iron Wollf's jars containing chemicals, to be again introduced, the same degree of positive or negative pressure being always maintained.

It may be desirable to impregnate the atmosphere of the chambers with the vapor of certain medicinal agents; it is an easy matter to place the substance to be used in the path of the air current, or more simply to put some drops of an essence on boiling water into the chambers. Pumiline essence I frequently and successfully use.

The compressed air bath more completely expands the pulmonary vesicles and increases their elasticity; the diaphragm and the base of the lungs descend lower; the respiratory process is more perfectly and less frequently performed; the peripheral circulation is less active, with some degree of decongestion of the skin and the mucous membranes (nasal, laryngeal, pulmonary, etc.); the pulse is less frequent and more full; the appetite and strength increase rapidly; the nervous system is undoubtedly invigorated. One may observe that these effects are corollaries of one another, and result either from mechanical or chemical action; indeed, the oxygen of compressed air is no longer oxygen, but some form of ozone.

The rarefied air bath has not been so well studied; nevertheless, it is employed with much success by some practitioners, who seek in it a reproduction of mountain atmosphere. It has also been recommended for rickety children, when the thorax is deformed. Recently it has been used alternately with the compressed air bath, when a doubt exists as to whether a patient should be sent to the mountains or to the seashore. The therapeutic uses of the air-baths are very numerous, but easily deduced from the foregoing considerations.

Asthma is the principal affection for which compressed air baths are employed. Eighty per cent. of recoveries are obtained after from twenty to sixty sittings. During the first sitting the dyspnœa disappears when the pressure of air is sufficient; this result becomes permanent only after a number of sittings.

In pulmonary emphysema the air-bath empties the vesicles and increases their elasticity, so that the dyspnœa diminishes. The first sitting is usually followed by a notable improvement. As in asthma, the success is generally striking and permanent. Pulmonary congestions, pulmonic processes, preceding or following pneumonia, and hæmoptysis, are cured mechanically, since the compressed air provokes anæmia of the pulmonary tissues. Chronic bronchitis and bronchorrhœa are always improved, so far as concerns dyspnœa, cough, expectoration, and general health. The first effects of the treatment are an increased expectoration, up to the point of completely ridding the lungs of mucus, and simultaneously a decongestion of the respiratory mucous membranes. The last action must be invoked in explaining the beneficial influence of compressed air in coryza, chronic pharyngitis, and laryngitis, and in that exaggerated susceptibility of the mucous membranes, as a result of which the patient is constantly exposed to the danger of catching cold. I have recorded two cases of chronic amygdalitis, in which resection had been contemplated, and in which I obtained complete cures by compressed air baths.

In whooping-cough, "the beneficial action of air-baths is undeniable," said Dujardin-Beaumetz. The cure is obtained after from ten to fifteen sittings; and generally the child gains from one to three pounds in weight. Jaccoud charges with gross neglect the physician who does not submit his consumptive patient to aëro-therapy. Oertel thinks the compressed-air treatment far superior to climatic treatment in any country. Professor Bertin (Montpellier) has recorded five cases of recovery in consumptives in the third stage.

Heart disease had long been considered the only drawback to aëro-therapy, but since I have successfully treated a number of cases with cardiac complications, I no longer hesitate to treat such cases, only using certain precautions.

In catarrhal deafness compressed air effects a natural catheterism. I have not infrequently seen patients suffering from asthma or other complaints emerge from the chamber declaring that their hearing was better than for many years.

Dujardin-Beaumetz says: "Compressed air baths are to be preferred to any other method of treating chlorosis, anæmia, diabetes, albuminuria, and gout."

Obesity, also, is favorably influenced, as a result of the acceleration of organic combustion, and the more active elimination of urea and carbonic acid.

In conclusion, I must add that Dr. Arntzenius has cured some cases of neurasthenia, and that I have recorded three observations of dysmenorrhœa permanently cured by a pneumo-therapeutic course. I think these results are due to the general invigorating power of the treatment.

Professor Klug, of Klausenburg, has been unanimously elected to fill the Chair of Physiology at the University of Budapest, made vacant by the death of Jendrássik.

HOT INFUSION OF DIGITALIS IN THE TREATMENT OF PNEUMONIA.

BY E. P. HERSHEY, M.D.,
OF DENVER, COL.

DURING the past three months, excellent opportunity has been afforded me to test the value of the treatment of pneumonia by means of large and frequently-repeated doses of the infusion of digitalis, given early in the attack. The marked benefits resulting in a few cases thus treated last fall suggested its great importance and bolder use. In twenty cases, the treatment was commenced by the administration of ten grains of the mild chloride of mercury, together with a tablespoonful of the infusion of digitalis, given every hour, as hot as the patient could drink it. In from six to ten hours, profuse perspiration occurred in every case, followed in twelve cases by a normal temperature. In three instances, the temperature, without the use of any antipyretic, dropped to 100°, in four, to between 101° and 101.5°, and in one, to between 103° and 105.5°. In no case was the temperature below 103° when first seen, and in all but one, it was ushered in by a distinct rigor. In all the cases the characteristic rusty sputum was present, but its short duration showed clearly that the inflammatory process had been cut short.

The severest case was that of G. J., a laborer, aged thirty-two, in whom there was violent delirium from the outset. The patient, having felt ill for nearly twenty-four hours, had a violent chill at 4.30 P.M., February 25th. At 6 P.M. the thermometer showed a temperature of 105.5°; the was pulse 130. His attendants had him strapped to the bed. Crepitant râles were heard at the base and over the middle lobe of the right lung, anteriorly and posteriorly. The patient was given ten grains of calomel, followed in one hour and a half by a tablespoonful of a hot infusion of digitalis, the latter being repeated every hour, despite the fact that the temperature at 11 P.M. had fallen to 103°, at 5 A.M. to 101°, and the pulse to 115, with a general improvement of all the manifestations of delirium. At 6 A.M. there was profuse expectoration of rusty-colored sputum, that continued for twenty-four hours. On the third day the temperature returned to 105°; after active purging, it fell rapidly. On the morning of the fourth day the pulse had dropped to 50, the temperature to 96°. The infusion of digitalis was discontinued, and a combination of camphor, strychnine, and quinine given. Convalescence was rapid, and just ten days after the beginning of the attack the patient was up and about. The loss of weight in this short attack was remarkable. At the beginning of the attack the man weighed about 168 pounds; on March 7th he weighed 144½—a loss of 23½ pounds.

That the hot infusion of digitalis acts quickly upon the cardiac muscle that forces the blood through the affected area and thus to a marked degree overcomes the dyscrasia, is probably the *rationale* of the action of the drug. The use of a large dose of calomel, by reducing the consistency of the blood, takes the place of the old-time method of bleeding.

Since investigating this subject, with the view of publishing the results obtained, I have read with no little interest the report of Petresco,[1] who used the remedy still more heroically, making an infusion of ten grains of the powdered leaves instead of seven, to the ounce, and giving a tablespoonful every half hour instead of every hour. There can be no doubt that the results obtained in the cases reported were due to the solution being given hot; I have found that, in the use of drugs intended to act quickly upon the circulation, their diffusion is more rapid if given hot. This method of administration was suggested to me by Dr. D. D. Stewart, of Philadelphia, who first reported that the administration of sulphonal in hot water gave better and more rapid results than when the drug was given dry or in cold solution. In the twenty cases treated no ill results followed these large doses of digitalis. However, it would be advisable to watch the circulation; in case of a sudden lowering of the pulse-rate, the infusion should at once be stopped, for this is an indication that the desired effect of the remedy has been obtained; should slow pulse and low temperature persist, nothing will stimulate better than camphor, quinine, and strychnine, in quantities suitable to the case. Alcohol was not used until the temperature had subsided. In none of the cases was the so-called standard remedy, carbonate of ammonia, used. Further investigation will be made with this method of treatment, and when a sufficient number of cases has been treated an additional report will be made. At present this method of treatment has yielded me far better results than any other.

A CASE OF MULTIPLE SARCOMA.[2]

BY AMAND N. RAVOLD, M.D.,
INSTRUCTOR IN BACTERIOLOGY, ST. LOUIS MEDICAL COLLEGE.

LAST June, while making a visit at the Good Shepherd Convent, I was asked to see one of the inmates, a penitent, who was suffering with a severe and persistent pain in her leg.

The patient was a handsome, vigorous, healthy-looking young woman, twenty years of age. She was cool and deliberate, and answered all questions frankly and truthfully. She said that for about a week she had been troubled with a constant dull, throbbing pain in her right leg, which from the beginning had steadily increased in severity. At first

[1] Lancet, April 18, 1891, p. 895.

[2] Read before the St. Louis Medico-Chirurgical Society, April 21, 1891.

she could detect nothing abnormal at the seat of the pain, but for the last few days she had been able to feel a small hard lump there. During the day while at work it did not annoy her much, but at night, and especially when in bed, it was worse, and for the last night or two had interrupted sleep. It had not as yet interfered with walking. On inspection I found nothing abnormal in the appearance of the leg, but about six inches below the patella, just on the inside of the tibia in the connective tissue between the muscles, I found a small hard ovoid mass about the size of a pecan, that felt like an enlarged gland and that was not freely movable. It appeared to be held in place by strands of tissue that ran into it from all sides, so that attempts to move it seemingly tightened these strands and caused a great deal of pain; simple pressure, though annoying, was not so painful. There was no history of a sore on the limb, nor were the glands in the leg, or thigh, or groin enlarged. Her health was good and had always been so. Her father and mother were living and in the best of health, their parents having been hard-working, long-lived people, with no history of malignant tumors, syphilitic or tuberculous diseases in their families. The patient's mother afterward confirmed these statements. I concluded that the tumor was a malignant growth, but of what kind I could not decide. Tuberculosis was excluded by the history, and yet the growth felt very much like an enlarged gland, and it certainly was encapsulated. Sarcoma it might be, but in the beginning, as a rule, sarcomatous growths are not accompanied by pain. Carcinoma it resembled more than anything else, but no history justifying the diagnosis could be obtained. I was quite certain that it was non-syphilitic. I told the patient that the only way to cure her trouble, since the infirmarian had failed to relieve her pain, was to remove the growth. This she mildly but firmly refused to have done, unless after a fair trial I should fail to afford her relief by medication. I am sorry to say that I consented to this arrangement, but I told her that the growth was a malignant one, and that although relief from the pain might follow the medicine, cure was possible only through surgical interference.

I ordered iodine to be painted on the skin over the tumor, and gave a prescription containing: Potass. iodidi, gr. 5; potass. bromidi, gr. 10; morph. sulph., gr. $\frac{1}{8}$; to be taken three times a day.

The date of this visit was June 24, 1890. I saw her again July 4th. When she entered the room I noticed that she was quite pale and that she limped a little, and was evidently suffering a great deal of pain. She said that for the last two days she had had pains in her left hip-joint and right groin, and that in the groin two lumps had made their appearance. On examination I found the mass in the leg fully twice as large as when I first saw it, and very painful to pressure. In the right groin just below Poupart's ligament two superficial glands were enlarged to about the size of an English walnut, and extremely tender to the touch. I was unable to find a growth of any kind about the hip, though pain deep in the joint was complained of. On my demand, Dr. H. H. Mudd was called in consultation. He visited her the same day, and advised an immediate operation. She again positively refused to be operated upon. He suggested that the sedative mixture be continued. In place of iodine, mercurial ointment was smeared on a piece of chamois skin and bound over the growths. This treatment and others that were afterward substituted for it failed to afford any relief. The mass in the leg grew at a fearful rate; within two weeks she was confined to her bed, unable to use her right leg, which was now twenty inches in circumference and exceedingly painful. The growth in the groin was painful, had spread to all the neighboring glands and was pushing its way through the tissues out upon the thigh, the abdomen, and down along the vulva. Within another week a swelling appeared over the upper part of the sacrum and spread rapidly. On the right elbow another growth showed itself, grew very fast in, about, and around the joint, and finally ankylosed it. About a week after this she complained of a feeling of fulness in her left eye, and on close inspection I could see that the eye bulged slightly, so that six weeks after the patient was first seen she was bedridden and suffering with five rapidly growing tumors. They grew in the following manner: From the gland-like encapsulated enlargements the growths spread in every direction, infiltrating and destroying all tissues save bone. The skin involved took on a brownish-yellow hue, and became thick, coarse, and harsh, resembling more the leather on a pig-skin saddle than anything with which I can compare it. In the skin and under it the blue tortuous veins could be distinctly outlined, while at occasional intervals telangiectatic collections of bloodvessels appeared, burst, and formed small blood blisters, which in their turn would break, discharge, and leave a quickly-healing superficial ulcer. The mass felt semi-solid and elastic to the touch, and in some places nodular. The pain was still dull, aching, and throbbing in characacter, persistent, but periodically worse or better.

She bore her sufferings with remarkable fortitude, but when asleep she would groan or cry out in distress. Opium afforded her rest, especially at night, and it did not interfere with her appetite, which remained good. The bowels throughout the disease were regular. About this time the pains in the leg changed for the worse, became lightning like in swiftness, and burning or tearing in severity. She said it felt as if some one had seized the mass with a red-hot, long-toothed vice, and was trying to crush it. The attacks occurred without apparent cause or warning, sometimes as often as every three hours, but, as a rule, not more than once a day. Terrible in intensity, they varied in length from a quick flash in and out of the tumor to those of several seconds' duration, and then vanished as quickly as they had come. She now became emaciated, showed marked cachexia, and became very irritable. Her cheerful look gave way to one of anxiety and despair. The mass behind the eye grew at an appalling rate, shoving the eye before it downward and forward as low as the level of the mouth, giving her a frightful

appearance. As she suffered no pain from it she refused to have it enucleated. The swelling in the groin had grown so large that it now turned the thigh outward and fixed it in that position, compelling the patient to lie on her back all the time; the tumor at the right elbow prevented the use of that arm, so that she was practically helpless. The growth at the sacrum had spread in all directions, and eventually broke down to form a large suppurating bedsore fully ten inches in diameter. This the nurses were unable to prevent, as the patient had become so apprehensive of the painful seizures, and so irritable and helpless, that she refused to allow them to move, or touch, or properly cleanse her. All through the hot month of August the patient's sufferings were horrible in the extreme. Early in September she complained of a difficulty in swallowing, and on examination a tumor was discovered growing between the œsophagus and the spinal column, on a line with the lower end of the larynx. It grew rapidly, soon prevented deglutition, and began to seriously impede breathing. Fever, which was contemporary with the formation of the bedsore, and probably due to absorption of the septic products from it, now became high and continuous. Finally, unable to take nourishment, and exhausted by fever and pain, she died on the 21st of September.

The mother of the girl refused to allow a complete autopsy to be made. I nevertheless secured a large piece from the mass in the leg at the sight of the original tumor, which, upon examination by Dr. H. C. Hartmann, proved to be a small round-celled sarcoma.

THE TREATMENT OF TINNITUS AURIUM.[1]

BY LAURENCE TURNBULL, M.D.,
OF PHILADELPHIA.

IT is not the object of this paper to dwell at length on the treatment of the various forms of tinnitus, but to omit a discussion of those that are well known and treated by every medical man, as for instance, the tinnitus dependent upon the presence of cerumen, pressing on the membrana tympani, that due to inflammation or abscess in the meatus, to an exostosis in the meatus, to catarrhal processes in the tympanum and Eustachian tubes, to perforation of the membrana tympani, or to a polypus in or near the same region, and to dwell on the more obscure forms encountered in disease of the internal ear, labyrinth, and auditory nerve, and on the reflex causes of deafness with tinnitus.

It is now well known that there exists a connection between the auditory nuclei in the medulla and pons and the cortical auditory centres of either side of the brain, and that the "sense of hearing is in greater part situated in the temporal lobe, and more especially in the superior temporal gyrus of this lobe." As Dr. Ferrier has stated,[1] tinnitus may occur in both ears as the result of unilateral irritation, owing to the intimate connection of the auditory nerves and the centres. The cases of sensory cortical discharge, reported by Hughes Bennett,[2] may be advanced, Dr. Ferrier thinks, in support of this view. Ferrier[3] quotes Baginsky as stating that the auditory nerve is in relation with the auditory centre of the cortex through the lower fillet of the corpora quadrigemina and internal geniculate body to the medullary fibres of the cortex.

According to Prof. Jones we may thus classify the principal sources of reflex irritation or inhibition of the auditory nerve: (*a*) Through communications at the nuclei of origin; more especially might this occur through the sensory fifth and tenth nerves; (*b*) through the communications with the facial in the internal auditory meatus, the reflections from this connection being transmitted along the petrosal nerves from the otic and Meckel's ganglia and the parts supplied by them; (*c*) through communications between the nerves supplying the tympanic structures and Meckel's ganglion and the otic and geniculate ganglia; according to Foster, the activity of the tensor tympani muscle is regulated by reflex action; (*d*) irritations may be reflected to the cerebellum or to the auditory centre, and be referred to the ear or to different parts of the head.

The researches of Gaskell are most important as to the presence and course of vaso-constrictor and vaso-dilator fibres (that control the blood-supply by constriction or dilatation of the small vessels); the former originate from the upper part and the latter from the whole length of the spinal cord; these fibres pass through the cervical ganglia of the sympathetic and thence to the various arteries, furnishing (in the case of the auditory nerve) the supply of blood to the ear, more especially through the internal auditory artery from the basilar. The fact is also of importance that certain nerves, as the trigeminus and the cervical sympathetic, appear to be supplied with special "pressor" fibres (McKendrick), that have the power of constricting the vessels, as a result either of direct or reflected irritation, which irritation, as in the case of the cervical sympathetic nerve, must have an important effect on the circulation of the ear.

Of the various other nerve-communications and distributions in the ear that bear on reflex irritation, I would remind you of the connections between the glosso-pharyngeal, fifth, and sympathetic nerves; as, for example, the innervation of the tensor tympani

and stapedius from the otic ganglion and the facial nerves respectively; the communications in the tympanic mucous membrane between Jacobson's nerve, the sympathetic and the geniculate ganglion of the facial nerve; and the other communications between the carotid plexus of the sympathetic, Jacobson's nerve and the otic and Meckel's ganglia, thus bringing all these nerve communications into direct relation with the superior cervical ganglion. The supply of the anterior wall of the external auditory meatus and the tympanic membrane from the auriculo-temporal is important as bearing on reflex irritations from affections of the external meatus, that cause tinnitus when the middle ear is healthy. This sensory supply, be it remembered, is connected with the facial and pneumogastric nerves.

With regard to the physiology of hearing, it does not appear that there are any proofs that separate centres exist for the perception of different kinds of sound. A sensation arising from any irritation transmitted to the auditory centre may be referred to the periphery, that is, to the origin of the nerve-filaments in the labyrinth (McKendrick). The receptive auditory centre is possibly in part situated in the cerebellum. Professor McKendrick (in a communication to Professor Jones) states that an irritation, either in the labyrinth, the auditory nerve, or the receptive centre will "produce a stimulus in the hearing-centre which will cause a sensation or a series of sensations which will always be referred to the labyrinth." Such irritation may be caused by anything that interferes with the normal equilibration of the fluid in the labyrinth or by any direct or reflected irritation of the nerves of the external meatus, the middle ear, or labyrinth. The irritation may follow or attend the presence of adventitious matters in the blood that circulates in the receptive centre, as well as alterations in the blood-supply dependent upon increase or diminution of blood-pressure. This latter condition, occurring either at the periphery, in the cerebellum, or in the course of the auditory nerve, would in itself be sufficient to give rise to irritation of the hearing-centre.

As Professor McKendrick rightly insists, it has to be remembered how exquisitely sensitive the auditory nerve-apparatus is, a fact with which all are acquainted who have studied the physiology of the ear in its perceptive powers and its faculty of differentiating, analyzing, and synthetically arranging sound-waves.

Certain disturbances in the equilibration of the labyrinthine fluid or reflex irritation of any part of the nervous apparatus of the labyrinth or irritation of the auditory nerve-nuclei may give rise to vertigo as an accompaniment of tinnitus. Stimulation of the cerebellum or of the cortical auditory centres may have the same effect; such stimulation may be reflected; under these conditions deafness is not a necessary accompaniment of the vertigo, nor is it absolutely necessary that there should be local aural changes discernible in those presenting the symptoms portrayed by Ménière.

CLINICAL MEMORANDA

REPORT OF A LUMBAR NEPHRECTOMY.

BY WILLIAM D. HAMILTON, M.A., M.D.,
VISITING SURGEON OF THE MOUNT CARMEL HOSPITAL, ETC.,
OF COLUMBUS, OHIO

ALBERT G., aged thirty-six, a dairyman, of Camp Chase, Ohio, was seen in consultation with Dr. H. P. Woodruff, of Alton, during January, 1891. He had had scarlatina in the preceding August. In October, 1890, he had suffered dull pain in the left loin, which followed the course of the ureter. He had hectic fever, and his urine contained a large quantity of pus. His appetite was poor, and he had lost fifty pounds of flesh in the past year. In the left loin, rather in the inguinal than lumbar region, could be felt a tender lump, shaped like a kidney, but several times the normal size of a kidney. Examination showed his lungs to be sound, and there was no evidence of involvement of the right kidney. Tests made by Dr. F. W. Blake indicated that the daily excretion of urea was about normal. The diagnosis made was that of scrofulous kidney.

A lumbar nephrotomy was done on January 10th, at the patient's home. It was found that the kidney had been converted into a number of cavities, containing thick pus and urine. An incision into the kidney allowed the finger to enter the pelvis. The abscesses were evacuated and a large drainage-tube was inserted at the middle of the parietal incision, three inches behind the iliac spine and near the crest.

On February 24th, forty-five days after the operation, the patient entered Mt. Carmel Hospital. There was free discharge of pus through the drain. He was passing more than a quart of urine daily. On only two or three occasions since the nephrotomy had he been without fever, and his urine had never been free from pus. His appetite was fair, and the sweats had diminished in the past fortnight. He slept well, had no pain and no chilly sensations, but had not gained in flesh or strength. The bladder was somewhat irritable. In the twenty-four hours preceding February 28th, the date of the second operation, he passed thirty-one ounces of urine. On account of the persistence of the symptoms, it was concluded that there were other tuberculous foci in the organ.

At 10 A.M. ether was given, Dr. Woodruff and Dr. Norris being present. Lumbar nephrectomy was done. The loin was washed with soap and water, and then with a carbolized solution. The patient was placed on the right side on a firm pillow, in order to put the other loin on the stretch. A six-inch incision was made half-way between the last rib and the crest of the ilium, parallel to the latter, and, in addition, an incision downward from the middle of the one described, freely exposing the fatty capsule of the kidney. Owing to the nephrotomy the parts were so matted together that the proper and fatty capsules were not easily distinguishable. Having incised

the fatty capsule enucleation was easily accomplished, thereby isolating the pedicle. A blunt needle threaded with coarse silk was passed between the ureter and the vessels, the lateral halves of the pedicle being securely tied. The several pus-cavities were cut into and the caseous contents were emptied, in order to diminish the size of the kidney and to facilitate its removal. It was cut away piecemeal with scissors, a large button of renal tissue, which was expected to necrose, being left to prevent the ligature from slipping. A saturated solution of the chloride of zinc was applied to the stump. The wound was flushed with hot water and dressed with gauze, through which the drains appeared. At 4.30 P.M. of the same day the pulse was 102. The patient was very pale. The dressings were soaked with brownish discharge and required changing. During the night he voided between eleven and twelve ounces of urine. In the six days beginning March 2d, the average quantity of urine passed daily was eighteen ounces. The stitches were removed on March 7th. The portion of the wound in which the pedicle lay was lined with granulations, and as the stump had not separated, it was constricted with rubber tubing. March 27th the stump and ligature came away. April 13th he was discharged convalescent. At one time there was a slight escape of gas and feces from the large intestine into the wound. Firm strapping, with absolute rest in bed, caused the fistulous opening to heal. The man is gaining rapidly in flesh and strength, and is entirely free from fever and sweats. The urine contains no pus and is abundant in quantity.

This is the fourth nephrectomy that the writer has done. The patients have all recovered. The other cases have been reported in the *Medical Register*, of Philadelphia, and the *New York Medical Journal*. In every instance a preliminary nephrotomy was performed. Occasionally this proceeding is curative, and the sequel determines the question whether or not the kidney be hopelessly damaged. However, Mr. Henry Morris, the distinguished English surgeon who has had a broad experience in operations on the kidney, prefers immediate nephrectomy, if the patient's condition permits.

THREAD- OR SEAT-WORMS.

By W. THORNTON PARKER, M.D., M.M.S.S.,
OF SALEM, MASS.

A recent communication in The Medical News concerning thread- or seat-worms has attracted my attention. Generally speaking, the medical attendant is less frequently consulted than the family druggist when treatment is needed for "worms." Especially in small towns do we find such-and-such a druggist more or less famous for his "worm" mixtures. The doses given by regular practitioners of medicine are sometimes of such nauseating character that it is found almost impossible to administer them to the little sufferers. The profession frequently regards thread- or seat-worms merely as a temporary annoyance, and does not attach great importance to their presence; and yet we often encounter children seriously ill from no other cause. While agency physician among the Chippewa Indians, I was called to attend several children so seriously infested with these parasites that I was unable to prevent a fatal termination. In recent years I have seldom used vermifuges, relying wholly upon the following course of treatment: Copious rectal injections of chloride of sodium in solution, or of boro-glyceride, one to twenty, followed by small rectal suppositories of boro-glyceride, have constituted my regular practice, invariably with good results. A dose of fluid extract of spigelia and senna in the morning, with a moderate dose of castor oil a few hours later, with reasonable attention to errors in diet and particularly as to the water-supply, is all the additional treatment required. It would seem to be unwise to dose the little patients with the risk of injury to the stomach and intestines for the sake of removing some irritating thread-worms, the habitat of which is the rectum.

ORIGINAL LECTURES.

PLEURISY WITH SEROUS EFFUSION—ACUTE CROUPOUS PNEUMONIA.

Abstract of a Clinical Lecture delivered at the Bellevue Hospital.

By ALFRED L. LOOMIS, M.D.,
VISITING PHYSICIAN.

Gentlemen: This man, twenty-five years old, was well until five weeks ago, when he was seized with pain in the side, passing up to the shoulder, for which he knew no exciting cause. There was no chill. He found that he could lie most comfortably on the left side. Two weeks ago he began to be troubled with shortness of breath and his appetite became poor. When admitted to the hospital his pulse was 92, the respirations 28, and the temperature 103.2°. Since then, the temperature has ranged from 101° to 103°, and to-day is 101.4°. The pulse has varied from 78 to 98, and the respirations from 20 to 28. The prominent symptom is pain; quite recently there has been added shortness of breath. The fact that dyspnœa was not present at the onset of the attack, would lead us to expect the existence of a serofibrinous pleurisy.

The countenance is not anxious; the right side of the chest does not move as freely as the left. The pulse is about 82, of pretty fair quality. The apex-beat is displaced to the left about one and a half inches, and is a little above its normal position. Hypertrophy of the heart might displace the apex-beat to the left, but it would at the same time depress it. Enlargement of the left lobe of the liver might displace the apex to the left and upward, but not to the extent that we find in this case. Anteriorly, over the upper part of the right lung, there is increased resonance of a tympanitic quality. Posteriorly, the chest expansion is found to be diminished to about an equal extent on both sides. Vocal fremitus is subject to certain variations in connection with pleurisy with effusion, and in order to understand the reason for these, it is necessary to refer to the physical laws governing the conduction of sound-vibration. Sound-vibration is not transmitted with equal readiness through media of different densities. Hence, if the lung be separated from the chest wall by fluid or plastic material, the vibrations of the voice must pass through the lungs, a structure containing air, and then through the exudation, which contains little air. Under such physical conditions, the sound is conducted very feebly, if at all. In certain

cases of pleurisy with effusion, bronchial breathing and increased vocal fremitus are present, while in others, these are absent. Ordinarily, the bronchial tubes are collapsed from pressure, but if the pressure is not sufficient for this, or if the bronchial tubes are very rigid, they may remain open, and so give rise to bronchial respiration, bronchophony, and increased vocal fremitus. In this patient the respiratory murmur is heard only above the middle of the right scapula, and the voice-sounds are a little more intense just at the point where the ear passes below the level of the fluid. Further down these sounds become more feeble, and finally are inaudible. It is probable that in this case the pleural cavity has contained even more fluid than it does at present; the absence of vesicular breathing and the extensive area of dulness, lead us to believe that the entire pleural membrane has been involved. In an uncomplicated case of sero-fibrinous pleurisy, the temperature rarely rises above 101° or 102°; although it has been unusually high in this case, it has not been high enough, nor have the constitutional symptoms been sufficiently severe, to indicate the existence of a suppurative pleurisy. In suppurative pleurisy the temperature is often 104° or 105°, and not infrequently higher than in acute pneumonia. There is also usually much more prostration than is present here. My impression is that the fluid has already begun to subside; this brings up the important question of treatment. The man has been sick for five weeks. If this were your first visit to the case, you would not aspirate immediately, unless the pleural cavity were distended with fluid and there were extreme dyspnœa. Under these circumstances, it would not be safe to leave the patient in such a condition. Some advise aspiration whenever the pleural cavity is two-thirds full of fluid; they claim that by this method of treatment recovery is hastened. My own experience leads me to a directly opposite conclusion, and I therefore prefer to wait, as I shall do in this case, until Nature has had a fair opportunity to remove the fluid herself. There is a great temptation to make an exploratory puncture with a hypodermatic syringe to ascertain the nature of the fluid, but many a serous effusion has in this way been changed into a purulent one. If such a procedure be resorted to, the greatest care must be exercised that the needle be aseptic.

The next patient is a man, thirty years old, who had been engaged in his occupation of a bricklayer until ten days ago, when he was suddenly seized with what he supposed to be chills and fever, as he had suffered from fever and ague a number of years before. Two days later he had another chill followed by fever, and on the following day he began to suffer from pain in the right shoulder, increased by deep inspiration. After two days more, the pain still continuing, but without a return of the chills, a cough developed, accompanied by a yellowish, fairly abundant and tenacious expectoration, that, after twenty-four hours, became of a reddish color. Just one week after the initial chill he was admitted to the hospital, with a temperature of 103°, that on the following morning reached 104°, and is at present 103°. The respirations have been between 30 and 36, and the pulse, that was 104 at the time of admission, has risen to 114. Examination of the urine has detected nothing abnormal. The patient's face has a decided purplish flush, that, in itself, would lead one to make a provisional diagnosis of pneumonia. The pulse is not only full and rapid, but also irregular and intermittent, in spite of the fact that he is taking an ounce of whiskey every two hours. The occurrence of profuse perspiration, in association with an elevated temperature, indicates a tendency to heart-failure. The apex-beat is in its normal position, but the heart-sounds are more indistinct than an examination of the pulse would lead one to expect; what is more important, the first and second sounds are quite feeble, and of about the same length. When, in the course of any acute disease, the heart-sounds present these characters, heart-failure is not an unlikely complication. Percussion shows complete dulness over the right apex anteriorly; auscultation over the same area reveals bronchial respiration and crepitant râles. Pleuritic friction sounds are heard low down on the same side. An examination of the chest, behind, shows distinct bronchial breathing on the right side, with beginning bronchial respiration on the left. Although the examination of the chest, posteriorly, has been made quickly, the effect upon the circulation of the momentary change to the sitting position is shown by a little blueness of the capillary circulation of the body and a more feeble and rapid pulse. Evidently, then, we have here an acute, croupous pneumonia of the right apex, already well developed, and a croupous pneumonia on the left side, that is just beginning. This man denies addiction to the use of alcohol, but when a man of his age and general physical appearance develops an apex-pneumonia, independently of any other disease, you can be almost certain that it is of alcoholic origin. This fact, together with the extension of the pneumonic process to the other lung, renders the prognosis grave. It is by no means uncommon in acute pneumonia for the respirations to reach sixty per minute; and yet this man's respirations have not been over forty; at present they are about thirty-six per minute; he does not appear to suffer from dyspnœa, although, as a rule, dyspnœa is more severe when, as in this case, the pneumonia is situated at the apex. The dyspnœa of pneumonia appears to depend upon the nervous temperament of the patient, rather than upon the extent of the pneumonic process.

The condition of the pulse and capillary circulation would seem to indicate the necessity of increasing the quantity of stimulants, but experience shows that when twelve ounces of whiskey in the twenty-four hours fail to give the heart proper support, a larger quantity will rarely do more than prolong the agony. Such large quantities are of value only in emergencies, to tide the patient over a short period of great danger. Digitalis, in my experience, is not useful, and in many cases is actually harmful; nor do I favor the administration of the carbonate of ammonia. In the early stages of the disease, when the nervous system is overwhelmed by shock, opium is of great service, but later on it is contra-indicated.

I have just come from a consultation in a case of pneumonia with a well-known practitioner of large clinical experience. His whole treatment was summed up in the two words: "food and rest," and this, too, when the patient's temperature was nearly 104°. Last spring, a most interesting research was made into the mortality of pneumonia under the various methods of treatment that had been in vogue at the Massachusetts General Hospital

during the past seventy-five years. During this period pneumonia had been treated by blood-letting, by calomel and antimony, by "the let-alone" method, by the stimulating treatment, and by the antipyretic treatment; when lines were drawn to represent the mortality it was found that, notwithstanding these widely differing methods of treatment, the mortality for the seventy-five years was represented by a nearly straight line. This speaks for itself.

TUBERCULAR SYPHILIDES—PITYRIASIS VERSICOLOR—ECZEMA CAPITIS—TINEA TONSURANS—FAVUS—IODIDE ERYTHEMA.

Abstract of a Clinical Lecture delivered at the New York Post Graduate Medical School.

BY ROBERT W. TAYLOR, M.D.,
PROFESSOR OF DERMATOLOGY AND SYPHILIS.

GENTLEMEN: The first patient brought to the notice of the class was a man, thirty-three years old, who had become infected with syphilis eight years before. He was admitted to the hospital with a patch on the right side of the face, extending from the root of the nose over the chin and under the eye. The skin was pinkish, infiltrated, and rough; the lesion was a mixture of the non-ulcerating and the ulcerating syphilide and had existed for about two months; it closely resembled lupus erythematosus. The "plugged-follicle" symptom was also present. Lupus is prone to develop in one or more discoid patches about the nose, that, fusing together, give rise to the "bat-wing" shape of the eruption, and to its name, *vespertilio*. The patient gave a history of syphilis and of treatment extending over a few months, but not long enough to eradicate the diathesis. If he had persevered in the treatment, the probabilities are that this late manifestation would not have appeared. The points of especial interest were: the late evolution, the absence of intermediary symptoms, the resemblance of the patch to lupus erythematosus, and the involvement of the follicles. The touch-stone in these doubtful cases is the treatment; in the present instance, a strong mixed treatment had produced a decided improvement.

The next case presented an eruption which, on account of its brownish color, was often mistaken for a syphilide, the case was all the more misleading to the inexperienced, as the patient had had syphilis fourteen years before, and because the eruption showed a tendency to form rings. The disease was *pityriasis* or *tinea versicolor*, a parasitic disease, that did not often form rings. In this patient the eruption was on the sternum and between the shoulders; it gave rise to no thickening of the skin. When an eruption is found distributed over the sternum and trunk to the neck, down on the arms to the wrists, and on the back between the shoulders, but sparing the latter, the case is presumably one of seborrhœa or of pityriasis versicolor. In the former the lesion appears rougher and more inflammatory; in the latter, the lesion shows no signs of inflammation, and microscopical examination of the scales would show the presence of the parasite, the *microsporon furfur*. Following the usual rule of making a thorough examination of the whole body, in the diagnosis of skin diseases, one is surprised to see about the legs, knees, and elbows infiltrated, scaly patches, that if seen independently of the patient's history, one would say were undoubtedly those of psoriasis. The diagnosis, however, in this case was a syphilide with much epidermal proliferation. The patient denied having had an eruption when a young man. Psoriasis usually begins in early life, and commonly appears in the non-syphilitic, although psoriasis may be observed to develop after syphilitic infection.

The parts affected with pityriasis should be well scoured and then washed with a solution of bichloride of mercury or of hyposulphite of soda. The syphilitic element in the case should be treated internally by a strong, mixed treatment, and the patches, after thorough soaking in an alkaline bath, should be well rubbed with the following ointment:

℞.—Oil of cade . . . . . ʒj.
Citrine ointment . . . . ʒij.
Vaselin . . . . . ʒj.

The next case was one of eczema capitis, and the child, about three years old, presented a pitiable appearance, with its face raw and oozing, and its scalp covered with pus and sebaceous matter. The condition was undoubtedly brought about by persistent washing and irritation, and usually begins in a small patch in the scalp.

The treatment consisted in correcting the acidity of the stomach by means of alkalies, and in a proper regulation of the diet. About every other day, a powder consisting of two grains each of calomel and sodium bicarbonate should be given; sometimes it is desirable to add a little Rochelle salts. After the crusts had been removed by the local application of vaselin, the following ointment should be kept constantly applied:

℞.—Camphor . . . . . gr. x.
Calomel } . . āā ʒj.
Goulard's Extract }
Vaselin . . . . . ʒj.

The attention of the class was next directed to a boy who had a number of small, shiny bald spots and scaly areas in the temporo-frontal region. The trouble dated back five years, at which time he had become infected with tinea tonsurans by wearing a schoolmate's cap. Considering the long duration, the disease had not made great ravages, but showed its characteristic pertinacity. If the disease were eczema there would be some evidence of inflammation, and in so long a time as had elapsed it would have covered the whole face. If one looked only at the bald patches, one might consider the case an anomalous one of alopecia.

The mode of infection in this case clearly pointed out the needful prophylactic measures. The curative treatment consisted in thoroughly shampooing the head and washing with a two per cent. solution of carbolic acid, after which the patches should he epilated and then painted over with the following:

℞.—Chrysarobin . . . . . ʒj.
Flexible collodion . . . . ʒj.

Proper attention to the case might be rewarded by a prompt cure.

In contrast with the foregoing, the lecturer presented a boy, nine years old, who also had a persistent disease of

the scalp. It had lasted two years, but unlike the other case, it showed no tendency to localize itself in small, circular spots. There were dry grayish-green crusts adhering closely to the scalp of the vertex and occipital region. This condition resembled that seen in only two diseases—*i. e.*, impetiginous eczema and favus. In certain places the crusts formed in the shape of a cup around the hair-follicles; on scratching the crusts they broke into powder. The crusts were at first green, but after a time they became blanched. This patient had favus, and after scratching or handling these crusts, one should be careful to thoroughly cleanse the hands, for the disease is liable to attack the epithelial structures and burrow under the nails. Favus of the scalp persisted for years, ultimately leaving the scalp almost entirely bald and converted into a large cicatrix. Favus might also occur on the body, forming the variety called favus of the epidermis. The infectious agent in this disease, the *achorion Schönleinii*, is a vegetable mould often found on rats and mice, and conveyed from them by cats and other domestic animals to persons. This parasite, like that of ringworm, burrows down into the hair-follicles, and finding a favorable nidus there, undergoes rapid reproduction.

The hair should be cut short, and the scalp thoroughly rubbed with vaselin; and wherever the crusts reappear they should at once be removed; otherwise they would be rapidly reproduced. The disease is most intractable; a cure can only be effected by the most persistent treatment. After the scalp had been thoroughly cleansed, it should be washed three times a day with a 1:3000 bichloride of mercury solution, followed by an inunction of two grains of the bichloride of mercury to an ounce of vaselin. In some cases, a strong solution of corrosive sublimate in alcohol (eight grains to the ounce) might be employed; but in all such cases one should be on the alert for toxic symptoms, which, in children, generally begin with pain in the abdomen.

Dr. Taylor then showed the results of treatment in a patient who had been presented to the class with a suspicious-looking indurated ulceration about the nose. The opinion was expressed that the lesion was a benign one, and the treatment (curetting and the application of balsam of Peru ointment) had already resulted in almost healing the spot.

The next case was instructive as showing a syphilitic eruption on one side of the face, and a well-marked iodide of potassium erythema on the other side of the face and on the forearms, that closely resembled a papular syphilide.

Locally, an ointment of equal parts of mercurial ointment and vaselin, containing one drachm of the balsam of Peru, should be applied. Internally, great care should be observed to administer only a minimum dose of iodide of potassium until the system would better tolerate the drug. Both mercury and iodide of potassium were needed; but if the latter were not judiciously administered, the cure would be delayed and the skin lesions aggravated.

Kentucky School of Medicine.—At the commencement of the Kentucky School of Medicine on June 18th, the degree of Doctor of Medicine was conferred upon 155 graduates.

CURRENT LITERATURE.

PREGNANCY AFTER CONSERVATIVE VENTRAL FIXATION OF RETROFLEXED UTERI.

SÄNGER has performed the operation of ventral fixation of the uterus nineteen times, fourteen times with removal of diseased uterine appendages, and five times with preservation of the appendages. He has had one fatal result, not due to the operation, but to septic peritonitis from pyosalpinx. The five cases in which the appendages were preserved are, of course, the only ones in which pregnancy could occur. Of these five patients one was a married woman, one a young lady of the better class, and three were unmarried working-women. The young lady, alone of the five, had not exposed herself to conception. Two of the remaining four became pregnant; the married woman a second time.

The married woman's two pregnancies following the operation took the following course: The operation was performed on December 15, 1887; menstruation ceased in March, 1889. In the early part of the pregnancy the patient had pains, evidently extending from the seat of fixation of the uterus. In the beginning of June the attending physician reported to Sänger that the uterus did not seem to grow directly upward, but seemed to be held at the points of suture. Discharges of blood occurred repeatedly. In August the patient aborted at the sixth month of her pregnancy. The macerated fœtus corresponded in size with a three months' fœtus. Six weeks later, when Sänger saw the patient, she was entirely well; the uterus had become involuted, and was anteverted as before.

In the second pregnancy the last menstruation occurred April 20, 1890. The first movements of the child were felt September 7th. Sänger saw the patient in the sixth month of her pregnancy. She had no complaints of any kind, and had had no bleeding. The pregnant uterus, as regards position, form, and movability, in no respect differed from a normal uterus. On February 7, 1891, the patient was delivered of a dead fœtus by version and extraction. In the latter part of her pregnancy she had complained much of pain in the abdomen and sacrum; ate but little, and for this reason was extraordinarily weakened. According to her reckoning, she was eight days over her time when the waters began to escape. In the last few days fever set in; the fœtal movements were not felt for three days before delivery; through the membranes the cord could be felt still feebly pulsating, but the child was dead when born.

The second patient had had a child four years before the operation of ventral fixation of the womb, which was performed June 21, 1888. Menstruation failed to appear in the beginning of October, 1888, about four months after the operation. A boy was born at full time, without artificial aid, July 1, 1889. The puerperium was normal. Six months later, when the patient was seen, the scar in the abdomen showed a slight separation; the uterus lay as before, anteverted, and, without having been loosened from its fixation, was entirely movable.

Sänger discusses the two pregnancies of the first patient, and shows that neither the abortion in the first pregnancy nor the death of the fœtus at full time in the second is to be attributed to the operation of ventral fixation. He then refers to the following reported cases in which pregnancy has occurred after this operation: Olshausen reports a case in which pregnancy was uninterrupted and birth ran a normal course. Klotz has operated sixty-two times; he has had two normal births with subsequent normal position of the uterus, and one normal pregnancy is still under observation. In eighty-one cases of vaginal fixation of a retroflexed mobile uterus, he has observed three normal labors and has had five normal pregnancies under control. Two of Leopold's nineteen cases have had normal pregnancies and delivery.[1] Pozzi and Baudouin report a case of Routier's in which pregnancy and delivery were normal, and the uterus maintained its fixed position. Vlaccos refers to a case of pregnancy following "hysteropexy." One patient of the six cases reported by Jacobs was in the sixth month of undisturbed pregnancy. Gottschalck reports a case in which hemorrhage and abortion occurred in the pregnancy, and attributes them to the ventral fixation. Sänger does not agree with him.

Sänger discusses the operation of ventro-fixation and its various modifications, and maintains his preference for his own method in conservative ventral fixation. By "conservative" fixation he means fixation with preservation of the appendages of one or both sides, no matter whether the uterus has been movable, wedged in, or fixed; while by "pure" ventro-fixation he means the operation when the uterus is completely movable and both appendages have been preserved.

Since conservative ventral fixation not only most certainly obviates the backward deviation of the womb, cures the disturbances associated with it, and relieves the patient forever from the pessary treatment, while it also does not hinder conception and leads to no disturbance of pregnancy and childbirth, even the puerperium being passed without drawback, Sänger concludes that the operation will at least preserve its appropriate place by the side of vaginal and other operative procedures for the treatment of the retroflexed uterus with normal appendages.

The effect upon conception and pregnancy is at all events the best standard by which to judge of the problem of the artificial antefixation of the retroflexed uterus.—*Centralblatt für Gynäkologie*, No. 16, 1891.

THE DIGESTIVE POWER OF THE ACIDS.

VARIOUS theories have been advanced as to the action of the various acids during the process of digestion. Most of the physiologists believe that hydrochloric acid is the only true acid of the gastric juice, the others being formed from the contents of the stomach and mixing themselves with the former. Some even believe that these other acids are hurtful, and that the function of the hydrochloric acid, in conjunction with the pepsin, is not only to peptonize the albuminoid substances but also to hinder, by preventing fermentation, the formation of lactic, acetic, butyric and other acids, the presence of which weakens and may even completely stop stomach digestion. Alongside of these theories is that of others diametrically opposed, who attribute all the digestive power to the organic acids and to lactic acid in particular. These results have been arrived at by two methods: (1) the examination of the digestive action of a natural gastric juice, the acids of which have been previously determined; (2) artificial digestions in glass tubes, the artificial gastric juice being formed by adding together pepsin and the acid the digestive value of which it is desired to determine.

From his researches in this direction Dr. Georges drew the following conclusions upon the peptonizing action of the acids of the stomach: (1) Hydrochloric acid is the acid which, combined with pepsin, is commissioned with the peptonization of albuminoid substances. (2) Lactic acid, as well as acetic and tartaric acid, are totally deficient in digestive action.

Thoyer having had occasion during the course of the year to make some observations upon this subject, has not been able to confirm the latter conclusion. His experiments have been conducted with every possible precaution and with the greatest care, and he believes that the results obtained are entirely trustworthy. These researches have been of three kinds: (1) The action of acids alone upon the albuminoid substances. (2) The action of pepsin taken singly. (3) The combined action of pepsin and the acids. Various acids were employed—hydrochloric, hydrofluoric, sulphuric, nitric, lactic, acetic, tannic, tartaric, oxalic and citric. These were placed in test-tubes, together with small cubes of hard-boiled white of egg and some filaments of fibrin, and allowed to remain for twenty-four hours in an oven at a temperature of 38° C. At the end of that time the digestions did not appear to have commenced in the tubes containing the white of egg; in the tubes containing fibrin the dissolution of the fibrin was complete, but in neither was found the slightest trace of peptones. This proves that the acids which are contained normally in the stomach, as well as others which may be accidentally discovered there, have not in themselves any peptonizing action. The acid pepsin of Boudault placed in tubes with the white of egg, hard-boiled, and with fibrin, has determined the formation of peptones. If, however, the pepsin is chemically pure, the slightest trace of peptones cannot be found in either the tubes of fibrin or white of egg after remaining twenty-four hours in the oven at 38° C.

In testing the combined action of acids and pepsin, acid solutions of from four or five, ten or twenty, or thirty parts to a thousand have been employed. The pepsin employed was perfectly pure. The experiments were conducted in the following manner: In one series of test-tubes ten cubic centimetres of the precipitated acid solutions were placed, and to

[1] A third case is reported in the Centralblatt für Gynäkologie, April 18, 1891.

these were added two centigrammes of pure pepsin and a cube of one gramme of the white of a hard-boiled egg. In a second series of tubes were placed fifteen cubic centimetres of the same acid solutions, then five centigrammes of pure pepsin and a two-gramme cube of white of egg. Finally, two other series of tubes contained the same quantities of acid solution and pepsin, and one- and two-gramme quantities of fibrin. The results obtained justified the following conclusions:

1. Hydrochloric acid is the acid that, when combined with pepsin, has the most power for transforming albuminoid substances into peptones.

2. Hydrochloric acid does not alone possess the peptonizing property; with it, but to a much less degree, a large number of acids may, when combined with pepsin, give rise to this transformation of albumin into peptone. Among these acids are sulphuric, acetic, oxalic, tartaric, citric, lactic, and hydrofluoric, which possess this property in different degrees.—*Soc. de Biologie*, No. 6, 1891.

METHYLACETANILIDE, OR EXALGIN.

IN the *Bull. Gén. de Thérapeutique*, No. 6, 1891, DESNOS has made a study of the merits of this drug. He says that the chemical formula of exalgin confirms the law established by M. Dujardin-Beaumetz, to wit: that the anti-thermic action will be especially developed in amidogenous derivatives, whilst the analgesic property will be at its maximum in the amidogenous bodies in which for one molecule only of hydrogen, one molecule of a primitive fat, especially of methyl, has been substituted. Exalgin presents itself in the form of a white powder, consisting of long, fine needles, absolutely tasteless, soluble in warm alcohol and in boiling water, but slightly soluble in cold water to which a small proportion of an alcoholic fluid has been added. The physiological effects produced by it in man are very interesting. The action of the drug seems to be entirely exerted upon the bulb and the cerebro-spinal system. Prominent in the impressions produced upon the brain is vertigo. The numerous varieties in which this presents itself are interesting. Sometimes, and this is most frequently the case, very quickly after the ingestion of the drug the patient complains of a slight mist, as of a veil stretched before the eyes, and this is all. This sensation may be fugitive; its duration is very variable, oscillating between five minutes and a half hour. Sometimes the patients have a sensation of rotation within themselves, or yet it is the surrounding objects which appear to them to revolve around them. In a woman it seemed that her bed sank into the floor, another believed that she was incessantly falling to the side of her bed, and one even grasped the opposite side of the bed to escape falling. These extreme cases are very rare. In general the patient is able, notwithstanding the vertigo, to rise and walk. As a rare exception the vertigo is accompanied with vomiting, and also rarely with chills or cold sensations. In certain patients, but rarely, the vertigo coincides with tinnitus aurium, or this may be replaced by heaviness of the head or by cephalalgia, by a tendency to sleep, or simply a state of torpor, which two patients compared to that in which they had previously been thrown by injections of morphine. Nevertheless, it should be remembered that exalgin is no more a hypnotic than it is an anti-thermic. If the patients sleep, it is because the drug has freed them from the pains which had kept them awake. Some other phenomena reveal an action upon the cord and spinal nerves. Thus, sweats are encountered which may be general and profuse, or limited at times to one region of the body, generally to that portion which is the seat of the malady for which the exalgin is administered. Thus, also, frequently tinglings are experienced, extending to all the members and the tongue, or solely to the points where the neuralgia exists. Some patients complain of flashes of light before the eyes.

All doses may provoke these nervous phenomena. Three and three-quarter grains may suffice, but it is generally when eight and a half grains have been injected that they may be observed. Then, again, large doses, eleven or twelve grains, may fail to produce them. In this dose, however, cyanosis may be observed, though of slight intensity, and not in any manner resembling the cyanosis of grave disease of the heart. The appearance of the free border of the lips is scarcely modified, and upon the skin of the upper and lower lip, and upon the naso labial ridge, a slight grayish-blue tint may be observed. This coloration is not of long duration, usually disappearing on the next day. An examination of the blood of patients to whom exalgin has been administered reveals an alteration of the globules, which seem to be almost, if not completely paralyzed, so that the gaseous changes are not carried on in the proper manner. There is also a diminution of the oxyhæmoglobin. Exalgin, therefore, has the property of giving rise to anæmia, although this is not a property exclusively belonging to it, but one that is shared by the other anti-thermic nervines. One of the interesting points in the administration of exalgin is the ease with which it is tolerated by the digestive tube. It does not engender any troubles of the stomach or intestines.

As to the dose of the drug, three and three-quarter grains at times suffice to produce a curative effect, complete and lasting. More than this should never be given at a time, but if need be the dose may be increased to two or three times this amount during the twenty-four hours. As M. Gandineau has shown, a tolerance for the drug may be established, so that in giving successive doses it may become necessary to increase the amount given. The affections in which exalgin is of the greatest service are the neuralgias, especially the facial neuralgias, involving one or several branches of the trigeminal, or the occipital nerve, especially if these are of congestive origin from cold or rheumatism. The anæmic neuralgias are, without doubt, very favorably influenced by exalgin. Intercostal neuralgias have been benefited, as also have been neuralgias of the various plexuses, and the ilio-lumbar pains consequent upon uterine and ovarian disease. The visceral neuralgias,

angina pectoris, and nephritic colic are benefited, as are also painful and hysterical menstruation. The tremblings of paralysis agitans may be controlled by its use.

PARTIAL NEPHRITIS.

Cuffer and Gastow, as long ago as 1887, wrote that simple interstitial nephritis could be cured entirely or partially, the inflammatory process localizing itself in some portion of the kidney, and this morbid condition being recognized by the constant presence in the urine of a small amount of albumin. In the desire of ascertaining more explicitly the significance and prognostic value of this albuminuria, which, in spite of every possible care, persists in an unvarying quantity in patients otherwise apparently cured, the same writers instituted a series of investigations as to this apparent anomaly, the results of which they have published in the *Revue de Médecine*, No. 2, 1891. They find that the condition is of more importance than would at first sight appear. Relying upon the modern theories it might readily be believed that one had to deal with a physiological or intermittent albuminuria or with an albuminuria of sanguineous or dyscrasic origin. Such, however, is not the opinion of Cuffer and Gastow. They have found that the permanence of the amount of the albumin is the consequence of a permanent lesion of the kidney, of a nephritis which has become partial, with a prognosis much less grave than the persistence of a notable quantity of albumin in the urine would seem to warrant. Their conclusions have been based upon clinical facts entirely, all anatomico-pathological proofs being wanting.

When, they say, in the course of a parenchymatous nephritis one sees, under the influence of a well-directed treatment, all the symptoms disappear, save a certain degree of albuminuria, it is useless to persist in combating this albuminuria from the moment that the rate of the albumin remains constant, no matter what may be the methods employed to cause its disappearance. The nephritis may be regarded as cured whenever all the serious symptoms have disappeared. The albuminuria which persists has an important semeiological significance, in the sense that it indicates a renal lesion, the gravity of which will depend largely upon the existence of the other symptoms that should be taken into account, either œdema or uræmia. Consequently, a persistent albuminuria of a fixed degree, while all the other symptoms have disappeared, indicates that the renal lesion is limited, that the nephritis has become partial. It does not present any gravity, it does not necessitate any continuation of the initial treatment, because if there remains a lesion it is no longer evidence of disease, and the lesion is nothing more than a sort of incurable infirmity. From the therapeutic point of view, these patients have nothing more to do than to exercise proper precautions in the management of this feeble point in their organism. All treatment in this condition becomes useless, and in consequence it may even become hurtful. Now, what is the nature of this albumin? To what should it be attributed? Is it the albumin of the blood, or of serum, or is it a pseudo-albumin? Is it peptonic in nature? Is the albuminuria physiological, intermittent, of a dyscrasic origin, mechanical or nervous? It is not due to peptone or to pro-peptone, because nitric acid and heat produce in the urine of these patients an opaque precipitate of albumin, a precipitate which never is produced with peptones and pro-peptones, the reactions of which are quite different; it is an albumin occasioning all the characteristics of the albuminurias of renal origin. The idea of physiological albuminuria cannot be readily entertained. The patients give a history of an infectious disease, possibly, which has produced a nephritis, usual under these circumstances—a nephritis which has always persisted, since it has not ceased to be characterized by the presence of the albuminuria. This albuminuria is not intermittent, either. It always exists; it is persistent at a fixed or nearly fixed degree, which is not characteristic of an intermittent albuminuria. No more can it be explained by ascribing it to a dyscrasic cause. The patients have not been poisoned, nor are they anæmic, or carcinomatous, or tuberculous. No mechanical reason can be found; no cardiac lesion, no active or passive congestion of the kidney. No arterio-sclerosis exists to explain its presence. It remains, therefore, to explain the persistent albuminuria by the presence of a persistent lesion of the kidney, a nephritis. The whole parenchyma of the organ is not involved; all is not sclerous. There are some healthy renal lobules alongside of others which have been nearly entirely destroyed. This nephritis may remain partial for a long time. It may have subacute or acute exacerbations, each time leaving a little less of the renal tissue to perform the work. In this way some of the glomerules will be entirely destroyed, while at other points there will exist simply a catarrhal desquamation. The patient will remain, therefore, infirm in one portion of his kidney.

The conclusions drawn from these studies are:

1. Whenever nothing will explain the persistence of a fixed and constant degree of albuminuria; whenever none of the therapeutic measures employed against this albuminuria succeeds, while notwithstanding, the patient is enjoying good health, it is necessary, if he has had previously all the symptoms of an acute nephritis, to think of a partial nephritis.

2. It is not necessary in these cases to make even a grave prognosis when the urine contains a considerable quantity of albumin (thirty to sixty grains). The patient is an invalid, but may live, on the condition that he observe certain precautions.

3. It is not necessary to confine these patients to their rooms, to submit them to a severe regimen and milk diet. This will result in anæmia and useless debility. No kind of alimentation has any influence upon the amount of the albumin in the urine.

4. It is necessary that they avoid all chilling and errors of regimen.

5. They must avoid all renal irritation. All medication liable to react upon the kidneys must be

banished. The astringents will be of great service in such patients.

6. If they are attacked with an infectious disease, care must be taken to guard against any renal congestion.

THERAPEUTICS OF SYPHILIS.

Dr. E. Kreis, of Zurich, says that, in spite of new methods and new remedies, we are still far from an ideal treatment of syphilis, one which will remove completely the syphilitic virus from the organism without injury. He first discusses the so-called abortive treatment by excision of the chancre.

Neisser believes that it is possible to check the outbreak of syphilis by excising the chancre. Jullien's belief, based upon a series of experiences, is that syphilis may be delayed in its course, or at least weakened, by excising the chancre. In one of his cases the patient had a chancre removed in 1880; he remained under careful observation free from syphilis for four years, and then died of typhoid fever. Another patient, who was operated on in 1881, has remained healthy to the present day. A third patient became reinfected with syphilis seventeen months after the first primary sore had been excised. Leloir's first experiences led him to declare excision of the chancre useless, but upon investigating the question afresh he obtained positive results. The following case is especially noteworthy: He excised a chancre in 1884, twenty-four days after the coitus in which infection had occurred. Subsequently there was slight cicatrization, with no induration, no swelling of the glands, and later no symptoms of syphilis. The very careful observation of this case extends to the year 1888. On the other hand, Neumann, Ricord, and Von Sigmond do not favor the method, and Ricord declares that the destruction of the primary sore is absolutely useless. Unna and Auspitz, however, have revived the treatment. Kreis thinks that at present we must conclude that excision of the chancre cannot abort syphilis. Nevertheless, he regards the operation as not only justified, but indicated for certain cases—if only to give a positive answer to the question and to adduce proof that the chancre is to be regarded as the local action of the infection and not as the expression of the general disease. The indications for the operation are: (1) absolute certainty of diagnosis; (2) operation as early as possible, before the lymphatic glands have been infected; (3) that the chancre should be typically formed and appear completely separated from the surrounding parts, so that it may be removed *in toto* without infecting the neighboring tissue.

A second question in dispute is as to the time when the general treatment of syphilis should begin—whether with the occurrence of the primary sore, the so-called preventive treatment, or with the occurrence of the secondary symptoms. Fournier, Mauriac, Jullien, Schwimmer, and others hope, by early mercurial treatment of the patient, to prevent secondary symptoms; or, if these should set in, to make the course milder. Doutrelepont, Köbner, Kaposi, Unna, and Neisser, on the other hand, take the position that the primary treatment generally fails to defer the timely appearance of the secondary symptoms, and that the latter often occur more obstinately and severely. Kreis agrees with Neumann in opposing early treatment. He says he has seen after it extremely obstinate affections of the mucous membranes of the mouth, and the occurrence of premature iritis, skin affections being absent. He thinks early treatment appropriate only for large chancres difficult to heal.

A third question of great importance is as to the most appropriate form and combination of mercury in the treatment of syphilis. Kreis concludes that mercurial ointment gives the greatest therapeutic effect with the least detriment. It may be employed as in the usual inunction "cure," or in the form of a soap containing metallic mercury, or in the form of a mull, as recommended by Unna. They are all only different methods of applying mercurial ointment, and are nearly uniform in their activity. The use of the *ung. cinerei* represents the best, most active and most permanent "cure."

How long should the mercurial treatment continue? Fournier especially has called attention to the fact that those cases which were not sufficiently treated, or which were treated for too short a time, were often followed by severe tertiary manifestations. He therefore thinks that the treatment of syphilis should be continued for at least three or four years; recently he has made the time still longer. Lang, Diday, Caspary, and Köbner combat the long-continued mercurial treatment, and maintain that such treatment leads to serious injury to the organism, both to the digestive organs and the central nervous system. Neisser is in favor of long-continued, but intermittent, treatment. Kreis regrets that we lack statistics of cases extending over a long time; these would give us the necessary light by which to decide the question. All cases, however, should not be treated according to the same plan.

He concludes that, though the present treatment of syphilis does not enable us to cure every syphilitic permanently, yet we can by proper treatment always get rid of the symptoms again. We must in most cases consider syphilis an absolutely curable disease, and always a relatively curable one.—*Correspondenzblatt für Schweizer Aerzte*, No. 5, 1891.

"I wish that we could begin again, start from our present position and long experience to take a deeper insight into human suffering. It would be a compilation of records of what we had journeyed through with our own fellow-creatures, and with a view of seeing how the suffering and misery are to be got rid of. There should be a rational therapeutics derivable from pathological teaching; but it cannot be gained by merely looking at lower agencies, which are disintegrating and crumbling to pieces, and which cannot develop into greater and higher usefulness. But see, rather, how we come to miss the greater constructive powers, and in missing them become conscious of failure and disappointment. In other words, a more practical pathological teaching is called for."—Dr. H. G. Sutton.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,

SATURDAY, JULY 18, 1891.

THE NOMENCLATURE OF PTOMAÏNES, LEUCOMAÏNES, ETC.

IF one attempt clearly and sharply to define the terms ptomaïne, leucomaïne, animal alkaloid, toxine and toxalbumin, he will find that not one of them can be defined so that it is accurately delimited from the others, either as to origin or as to qualities. The best authors are not at all agreed as to the definitions that should be used; all complain of the defects and vagueness of any classification or definition. Take the word about which there is the least doubt: a ptomaïne is said to be a putrefactive alkaloid, a product of katabolic tissue-metamorphosis under the influence of bacterial agency. From its root and derivation a ptomaïne should be found only in the dead animal body, πτωμα meaning a cadaver; but ptomaïnes may be formed in the living as well as in the dead body. The name is, therefore, the outcome of a mere accident on the part of the first discoverer, and with scientific research has become a misnomer and misleading. SELMI should have designated these substances from an essential, not from an accidental factor of their origin. The chemical changes that take place in the cavities of the body may be quite as removed from the action of the living tissues of the body as if they occurred in a dead body miles away. In attempting to clear up the indefiniteness surrounding this subject BRIEGER has greatly increased it. He has proposed still to call the non-toxic basic products ptomaïnes, but designates as toxines those that are poisonous. Again an accidental instead of an essential etiological or qualitative fact is made the basis for a name. Some of the ptomaïnes are innocuous, some only slightly toxic, some intensely so, some harmless in single or moderate doses, some cumulatively toxic, or poisonous in large doses. The term toxine, if employed at all, should comprehend any toxic alkaloid whatever. As used by BRIEGER it is inaccurate. In the same way the word leucomaïne is incorrectly applied to substances analogous to ptomaïnes, but formed in the living instead of in the dead body; but if ptomaïnes are basic alkaloidal substances that may be formed in the living body, and leucomaïnes are precisely similar substances also formed in the living body, the definitions evidently overlap. A ptomaïne may be a leucomaïne, or *vice versa*. The confusion becomes greater when it is added that leucomaïnes may be products either of fermentative (or microörganismal) action or of physiological katabolism. The term animal alkaloid is sometimes used instead of ptomaïne, but is defective, as VAUGHAN and NOVY have pointed out —in that these substances, or some of them, may be produced in decomposing vegetable matter.

As if the confusion were not yet great enough, BRIEGER and FRAENKEL have proposed the term toxalbumin to designate those toxic proteid substances formed within the living body as a result either of fermentative changes or of normal katabolism. Now, "while it is true that some belong to the albumins, others are more truly albumoses; others are most closely related to the peptones; and still others differ in some important respects from all these."[1] Again an accident furnishes a name that renders all distinctions impossible, whilst the name itself in several respects implies positively incorrect descriptions.

It thus becomes apparent that further use of these terms, especially those latest invented, must be given up. The indefiniteness is already so great that but few specialists, even, have a clear grasp of the distinctions attempted to be conveyed by the over-

[1] From advance sheets of the new edition of the work of Vaughan and Novy, kindly furnished by the authors.

lapping and misleading definitions, with their implications of false etiology, doubtful origin, and erroneous qualities and connotations. Our best authorities, DRS. VAUGHAN and NOVY,[1] have sought to obviate these misdefinitions and misunderstandings, by substituting for the criticised terms the term "bacterial proteids," to designate those proteid bodies formed by the fermentative action of germs, while those constituting an integral part of the cell are named "bacterial cellular proteids." In one sense this is a move in the right direction, but in another it seems much like piling Pelion upon Ossa. All the products of bacterial action in the economy are not proteids. Non-bacterial pathological katabolic products are left unnamed and unclassified. It would seem wiser to dispense entirely with the old nomenclature, and if possible start entirely anew.

not all anabolins are quite certainly physiological products of the constructive processes of life and health. The katabolins are to be divided into—first, the normal, or those that are the natural and necessary products of healthy tissue-katabolism; and, second, the pathological, or those resulting from microbic influences, or abnormal processes, whether in living or dead bodies. The last group, of course, comprises all those heretofore classed as ptomaïnes, leucomaïnes, toxines, and toxalbumins, and is to be subdivided into two chief classes—the autogenetic, or those the products of non-infectious or non-bacterial morbid processes, and the heterogenetic, or germ-produced. The accident of toxicity may be expressed by the adjective toxic, or by the compound toxikatabolin. The accident of origin in living or dead tissues is readily indicated by adjectives or easily-formed compounds.

- **METABOLINS.** Products of metabolism from the inception of ingesta to their decomposition end-products.
  - **ANABOLINS.** Products of anabolic activity; substances of progressively increasing complexity.
    - NORMAL.—The natural products of healthy, retrograde tissue-metamorphosis.
  - **KATABOLINS.** Products of katabolic processes; substances of decreasing complexity.
    - *Toxic or Non-toxic.*
    - *Alkaloidal or Basic.*
    - *Microbic.*
    - *Albuminoid.*
    - *Nitrogenized.*
    - *etc. etc.*
    - AUTOMICROBIC.—The excretory products of the bacterium.
      - Varying with food and media, toxic or non-toxic, pathologic or non-pathologic, etc. etc.
    - PATHOLOGIC.
      - AUTOGENETIC.
        - Produced by non-infectious or non-microbic morbid processes.
      - HETEROGENETIC.
        - *a.* Substances produced by the action of the parasite upon the tissues or media, or by the reactions of the tissues or media to the microörganismal irritant (*ptomaïnes, toxines, etc.*)
        - *b.* Substances produced by the reactions of the tissues or media to automicrobic katabolins, or by mixtures of Class *a* and automicrobic katabolins.

The most essential, fundamental, and characteristic fact about all these infinitely various substances is that they are metabolic products, whether physiological or pathological, self-produced, or germ-produced, toxic or not, etc. Why not, therefore, designate them by the generic term Metabolins—subdivisible, of course, into anabolins, or those metabolins with increasing complexity of construction, and katabolins, or the metabolins of the descending series. These terms are neutral and colorless so far as concerns possible false implications, and while they are comprehensive, if used with qualifying terms they seem sufficiently designatory.[1] Most if

This scheme apparently leaves out of consideration the products of microörganismal activity in artificial culture-media, and also the exclusively excretory products of the bacteria themselves, as distinct from the consequences of their action upon the living tissues, or the reactions of the living tissues to the bacterial irritation. In answer it may be said that microörganismal products arising in artificial culture-media differ in no essential property from those produced in the culture-media of ante-mortem or post-mortem animal tissues, and they may very properly be included among the microbic or heterogenetic katabolins. They might be called artificial katabolins. As to the exclusively excretory products of microörganisms, they are also truly katabolins, and may, if desired, be called

[1] Loc. cit.

[2] The terms Metastate, Anastate, and Katastate were devised for and have been used to represent purely physiological products.

microbic-excretory or automicrobic katabolins. It goes without saying that about these questions a world of mystery awaits clearing up, and all that can be done is to adopt a nomenclature that does not stifle investigation and confuse the mind.

A schematic view of the nomenclature here recommended is given on the opposite page.

THE SUMMER CARE OF INFANTS.

"The melancholy days have come," the saddest in the calendar of infancy, when the sterilizer, the intestinal antiseptic, and the patented and infallible food hold sway. With that constant tendency so long observed in medicine, the pendulum is slowly swinging from the extreme of antibacterial prophylaxis to a reconciliation between old usages and new theories. The first to make sterilization popular, Soxhlet, in recent numbers of the *Münchener medicinische Wochenschrift*, announces modifications in sterilization, doing away with stoppers, substituting for them thin sheets of rubber to be tied over the bottles; the expansion of the rubber permits the exit of gas set free during heating. He does not find sterilized milk the universal food so long sought, but in common with Leeds and others he has observed that in some cases fat is so emulsified by sterilization that the milk becomes less digestible. All observers look to reforms in dairy hygiene and milk-producing for the next substantial advance in securing a suitable food for infants. In this connection the suggestion of Brush, to separate as far as possible the production of milk from the breeding of cattle, is a wise one. Under circumstances favorable for the growth of noxious bacteria, prolonged sterilization and intestinal antisepsis are of proved value, and the field for future study in this, as in so many other departments of medicine, lies in separating noxious from innocuous bacteria, and in a better knowledge of the means for destroying the one and utilizing the other. In brief, in hospital and city practice, during the heated term, sterilized milk, intestinal irrigation, and antisepsis, with stimulation and supplementary feeding, will prolong the lives of foundling and artificially-fed infants until they can be taken into the country or until cooler weather returns. For infants born of healthy parents amid good surroundings, scrupulous cleanliness and regular feeding, under the guidance of that rare scientific faculty, common sense, with an outdoor life, are in the majority of cases sufficient.

Sterilized milk, although usually unnecessary, may at times agree when nothing else will. The golden maxim remains, in spite of bacteria and ptomaines, that that which nourishes the human being is proper food, that each individual is a law to himself, and that only patient observation can read that law.

THE RECENT EXECUTIONS BY ELECTRICITY.

The officers of the law charged with the recent execution of the four criminals at Sing Sing, N. Y., have done their unpleasant work with most commendable skill and judgment. It was exceptionally necessary in the present case that there should be no bungling of any sort. Everyone felt that mistakes might naturally occur in the first trial of the novel method of execution, but that in these later cases the decisive test was to be made. It now appears that dispassionate minds are generally in agreement that, granted the frightful necessity of capital punishment, a great stride out of barbarism and brutality has been made with the adoption of the new method of execution by elcctricity. There seems to be nothing to add to the carefully weighed judgment of Dr. A. D. Rockwell, of New York, who was present at the execution and post-mortem examinations. In a letter written The News July 8th, Dr. Rockwell says: "The executions on Tuesday demonstrated to the satisfaction of myself, as well, I think, as of all others present, that no method for the disposition of criminals condemned to death could better meet the requirements of decency and efficiency, and that it ought to supplant everywhere the barbarous process of hanging. Through electricity death comes instantly, painlessly, and unattended by mutilation, convulsions, or any distressing outward manifestations of pain. Post-mortems after death by electricity invariably reveal the fact that no gross lesion or rupture of tissue has taken place. The nerve-centres and heart are instantly paralyzed, and life ceases."

"Twenty years ago we were steering well and steadily toward great principles on the preventive as well as the curative side of medicine; then there crept in the wild enthusiasm for bacteriological research—research good enough in its way as a piece of natural history and as disclosing some curious vital phenomena developed under morbid states of the organic structures and the blood, but a positive insanity when accepted as the one absorbing pursuit, restoring the humoral pathology, ignoring nervous function, leading to Babel with its utter confusion of tongues, and separating for a time our modern art of cure from the accumulated treasures of knowledge, wisdom and light of over two thousand years."—Dr. B. W. Richardson.

REVIEWS.

Philadelphia Hospital Reports. Volume I., 1890. Edited by Charles K. Mills, M.D., Member of the Neurological Staff. Large 8vo., pp. xii., 353. Philadelphia: Detre & Blackburn.

Both scientific and clinical medicine are to be congratulated upon the step taken by the Medical Board of the Philadelphia Hospital in so wisely imitating the example of the large general and special hospitals of Great Britain and Europe, by bringing before the medical profession at large the representative work of its members in a collective form, instead of allowing the great wealth of its recorded material to be scattered throughout medical journals in such a desultory way that no adequate idea of the real amount of work done in such an institution can be obtained by anyone not actually acquainted with the staff.

This, the first volume, which has been under the judicious care and watchful eye of Dr. Mills, contains a most interesting account of "The Medical History of the Philadelphia Almshouse," by D. Hayes Agnew, M.D., followed by two facetious and happy addresses by Alfred Stillé, M.D., in which the historic Blockley cockroach is mentioned. After a contribution upon numerous historical memoranda by the editor, come twenty-five important articles on medical subjects, founded on work done in the hospital wards by various members of the staff. These embrace the results of anatomical studies, experimental research and clinical diagnosis, with the effects of both surgical and medical therapy in nearly every department of medicine. A few brief accounts of the most important epidemics occurring since 1862, by Dr. R. G. Curtin, practically closes the book.

Of course, in the initial volume of such a series of reports, much that is descriptive and reminiscent has been inserted; this should always be when there is so much to interest and so much to show the progress of practical medicine in a large charitable institution like the Philadelphia Hospital. It is to be sincerely hoped that enough fresh clinical material and sufficient additional historical data may soon be obtained to permit of the early appearance of a second report.

A Treatise on the Diseases of the Nervous System. By William A. Hammond, M.D., with the collaboration of Græme M. Hammond, M.D. Illustrated. Ninth edition. New York: D. Appleton & Co., 1891.

There are few books, even upon those subjects which are constantly in the ordinary physician's mind, which succeed as has that of Dr. Hammond; and when we recollect that when the first edition of this work appeared, neurology in America was in its very infancy, the rapid exhaustion of its editions is the more remarkable. In the ninth edition the writer's son has done much toward keeping the work abreast of the times, and, with more confidence than ever, it can now be regarded as one of the best and most satisfactory works on nervous diseases, either for the practitioner or for the advanced student. The book is beautified and its usefulness increased by a larger number of illustrations than heretofore—among the best from a medical point of view being those representing syringo-myelia, which have been taken from the studies of Van Giesen. In the article on tetanus the microbic nature of the disease is dwelt upon at very proper length, but the fact that tetanus is sufficiently contagious to require isolation is not stated, while the possible influence of certain soils which are capable of causing the disease, by reason of the germs which they contain, is also ignored. In regard to hydrophobia, so called, Dr. Hammond thoroughly believes in its existence, and also asserts that the bite of a healthy animal, such as the dog, may produce the disease in man. In regard to Pasteur's treatment, the author says that if he were bitten he would prefer to rely upon the cautery rather than upon inoculation.

A Compend of Equine Anatomy and Physiology. By William R. Ballou, M.D., Professor of Equine Anatomy and formerly Lecturer on Physiology, New York College of Veterinary Surgeons; Instructor in Genito-urinary Surgery, New York Polyclinic; Surgeon, Bellevue Dispensary; late House-Surgeon, Bellevue Hospital, New York. With 29 graphic illustrations, selected from Chauveau's *Comparative Anatomy*. Philadelphia: P. Blakiston, Son & Co., 1890.

This anatomical and physiological *résumé* is admirably adapted to the purpose for which it is designed. Containing all the essential points of the anatomy of the horse, it may be consulted in the dissecting-room by those preparing for examination, and for hasty reference afterward. As its author explains, the book is mainly a compilation, and we add, it is well arranged and the work done with great thoroughness. The nomenclature, where practicable, is that adopted by the general medical profession. The only thing omitted is a mention of the principal anatomical differences between different species of domestic animals, a brief enumeration of which should perhaps form a part of a work of this kind. Since it is especially intended for veterinary students, it would be well to incorporate these in a later edition.

Practical Notes on Urinary Analysis. By W. B. Canfield, M.D., Lecturer on Clinical Medicine, University of Maryland. [Physician's Leisure Library.] Detroit, Mich.: George S. Davis, 1891.

In this little monograph the author has collected and well arranged all that is known concerning urine analysis up to date. The field has been so thoroughly and carefully covered that the only claim for this work can be, that the latest tests, such as the trichloracetic acid test for albumin, and the phenylhydrazin and indigo-carmine tests for sugar, are fully elucidated. The author describes the normal as well as abnormal constituents of urine, and also the various bodies found in the sediment.

The urine of fever, of acute and chronic nephritis, of contracted and amyloid kidney, of diabetes, uræmia, cystitis, and calculus, is carefully considered. One great merit in the book is its condensed form, the practitioner being able to find at a glance, without wading through a lot of more or less useless matter, what he may desire. The plates, especially those depicting sediments and the various kinds of casts, are very well drawn.

As a ready-reference book for instantanous use, this little volume will be of much service.

Digestion and Diet. By Sir William Roberts, M.D., F.R.S. Pp. 261. Philadelphia: Lea Brothers & Co., 1891.

It is only when the physician is brought face to face with a case of disordered digestion that he finds himself wishing either that his memory concerning physiological functions were better, or that in college days his teacher had more clearly shown the practical distinctions between normal and abnormal preparation of food for assimilation. To all those who feel puzzled when dealing with such cases we recommend this book. It contains so much valuable information, and so succinctly sums up the most recent views in regard to digestion and indigestion, that it affords a reliable guide of a convenient and readable size. In some respects the book resembles that of Brunton upon a similar subject which contained papers read or addresses made before learned medical societies on those subjects, and which some years ago was so deservedly popular.

The Care of the Eyes in Health and Disease. By D. N. Skinner, M.D. Boston: J. G. Cupples & Co., 1891.

This little book discusses in a popular manner the anatomy and physiology of the eye, the defects of vision and their treatment by spectacles, some of the common diseases of the eye, suggestions in regard to the care of the eye, and the result of school life upon the visual organ. There is nothing very original in the book, but it certainly is a conscientious statement of the subjects which have been mentioned, and might with profit be read by the general practitioner, and be placed in the hands of those who have children under their care, especially children in their early school years. For the most part the advice given is sound, and stated in such a manner that anyone, be he layman or doctor, may read it with profit.

"Joe Brown," Doctor, on Alcoholism: Its Cause and Cure. New York: E. Scott, 1891.

This anonymous publication of one hundred and five pages presents a vivid picture of the horrors of alcoholism. The alcohol habit is considered a disease. The author, in his zeal, errs in denying alcohol any medicinal properties. The remedy recommended for the habit—abstinence and forced nutrition—is rational and practical. The little work is clearly a "temperance" document, and its force is somewhat weakened by the evident bias that pervades it.

Medical Symbolism in Connection with Historical Studies in the Arts of Healing and Hygiene. By Thomas S. Sozinsky, M.D., Ph.D., etc. Illustrated. Philadelphia and London: F. A. Davis, 1891.

This scholarly little work is the enlargement of a journalistic essay previously published. It has received the praise of Drs. Frances Emily White, Weir Mitchell and Henry M. Smith, and well deserves it. The history of medicine receives too little attention from medical students, and the attempt here made to illuminate the mythological aspects and origins of the science deserves commendation.

Le Journal de la Société Médico-Chirurgicale Canadienne-Française de la Nouvelle-Angleterre is the name of a new monthly, published entirely in the French language, at Lowell, Mass., the first number of which appeared in January, 1891. Dr. E. Sirois is the secretary of the editorial staff. The fact is of interest as showing how the native New Englander is being crowded upon by the French-Canadian.

CORRESPONDENCE.

LETTER FROM NEW YORK.

Popularization of the Subjects Discussed at the New York Academy of Medicine—Proposal of an "Air Garden" over a Reservoir—Public Baths—Union of the College of Physicians and Surgeons with Columbia College—The Post-Graduate Medical School—The House of Rest for Consumptives at Tremont—The Eastern Dispensary—The Abuse of Medical Charity.

In my last letter I referred to some of the interesting discussions that had taken place in the various societies of this city, and particularly to those bearing upon the subject of the new treatment of tuberculosis. The present attitude of the medical profession here upon this now well-worn theme was accurately stated in a recent report that you published, of a formal discussion held at the New York Academy of Medicine. This body of medical men has shown much energy in the work of the past winter, and in no section perhaps has this been so apparent as in that on "Public Health." The change is the more gratifying because hitherto this very important department has received but little attention; in fact, the attendance at the meetings was so small that one of the members told me that an effort would be made to bring the subjects for discussion to the notice of non-medical persons, and that, at any rate, the section was determined that its apparent inactivity should no longer be a reproach to the Academy of Medicine. This purpose has been steadfastly kept in view, and with such success that on one occasion the usual meeting-room was not nearly large enough to accommodate the audience. At one of these meetings they took up the matter of the proposed "air garden" over the Forty-second Street reservoir, which a very enterprising daily newspaper was endeavoring to make its readers believe would fill a "long-felt want." Strange as it may seem, this journal, which so constantly boasts of being "the champion of the people," nearly succeeded in perpetrating this outrage in the name of humanity, and had actually secured the passage of the bill in one branch of the Legislature. The prompt action of the Academy of Medicine resulted in the defeat of the measure, and I only mention the subject to allude to one or two points of general interest that were brought out in the discussion.

In addition to the almost self-evident fact that a pool of water in the centre of a large city, when deprived of the purifying influences of sunlight and air, must of necessity prove a source of disease, attention was

directed to the practical engineering difficulties in the way of preventing the pollution of the water from a beer garden above it. It was alleged by the promoters of this scheme that the water of this reservoir would be used almost exclusively for fires, but supposing that its use was so restricted, the infection of the general water supply would not be prevented, because the same pipes were used for drinking purposes and for fires. As an instance of the great difficulty in detecting the source of pollution in the water supply, one of the speakers referred to an experience at a certain asylum, where a careful examination of a distant drain, and the usual chemical analysis of the well-water failed to show any contamination, and yet shortly after some chloride of lithium was placed in the asylum sink, the presence of this salt could be detected in the well-water by spectroscopic examination; and on ceasing to use this water, an epidemic of typhoid fever that was at that time raging in the institution was speedily checked.

The matter of public baths has been brought to the notice of the Academy and of the public generally by Dr. S. Baruch. Although some people may consider this gentleman a good deal of an enthusiast on hydropathy, few will deny the crying need in our city of better bathing accommodations. To hear Dr. Baruch describe the delights of the "rain bath" is almost enough, I should think, to persuade even the poor Italians to run the risk of a bath, and certainly, in all soberness, it must be said that the "rain bath," which is the form advocated for public use, has much to recommend it, on the score of both economy and efficiency. The matter has been taken up by the Society for Improving the Condition of the Poor, and it will not be long before these baths will be put to a practical every-day test. The construction of one has already been begun, and it is expected that it will accommodate 500 persons daily.

The Faculty and Alumni and in fact all connected with the old College of Physicians and Surgeons are just now in a state of jubilation over the union of the college with Columbia College. The Faculty is glad, because they have found the care of the splendid gifts of the Vanderbilts almost beyond their means; the instructors are happy, because they see in it some chance of receiving remuneration for their services in the clinic, while the graduates are pleased, as they see in it a prosperous future for the college, and the assured independence that will do much to raise the standard of medical education.

The Faculty of the Post-Graduate Medical School recently held its annual dinner, and the occasion was made doubly enjoyable by the announcement that the sum of $5000 had just been given to assist in purchasing the two buildings adjacent to the school, so that better accommodation might be secured for the constantly increasing classes.

It is with pleasure that I learn that the House of Rest for Consumptives at Tremont has passed into the hands of the trustees of St. Luke's Hospital, for this hospital is well known as having set an example in the matter of caring for consumptives that it would be well if our other metropolitan hospitals would imitate. The understanding is that the hospital will maintain forty beds for the care of consumptive patients. It certainly seems strange that in this city, where new hospitals are constantly springing into existence—for some of which it must be confessed there is but little real demand—that the sore need of adequate provision for consumptives and incurable cases, as well as for convalescent patients that are crowded out of our general hospitals before they are able to go to work, should be overlooked. Large sums of money are divided up among many hospitals, all more or less worthy, while the incurable, and in medical parlance, the "uninteresting" cases receive but little aid. It would be well indeed if our hospitals would pay more attention to the humane aspect of their work and less to the mortality rate and the "interesting" character of the cases they admit.

The large dispensary down town on the crowded East-side, at the corner of Essex and Grand Streets, so long known as the Eastern Dispensary, has been removed to its handsome new home on the corner of Broome and Essex Streets, and its name has been changed to the Good Samaritan Dispensary. It was quite recently opened with appropriate ceremonies, and those who were present on that occasion and inspected the new building were impressed with its elaborate appointments. On the first floor, as the patients enter, they are received by a physician and classified, and those found to have contagious diseases are sent into small isolating rooms and the Board of Health notified. They are prevented from prematurely taking their departure, pending the arrival of the health inspector, by the fact that the doors to these rooms have the knobs only on the outside. An elevator is provided for the use of the patients, who are given different colored cards that show the respective departments to which they are to be distributed. As the cases are classified, brief histories are taken down by a stenographer and typewriter operator employed for that special purpose. It is doubtful whether the wretched and densely ignorant people who throng this dispensary appreciate their privileges, but certain it is that the luxuries now offered by some of our modern dispensaries, such as the Vanderbilt Clinic, are so well appreciated that people in *comfortable* circumstances come from far and near to them, and instead of doing this in secret, they now take pleasure in telling all their friends about how nicely they were treated by the various "professors," and usually wind up by recommending their friends to go and do likewise. In connection with this subject, I cannot refrain from referring to the last report of the Demilt Dispensary, which contains some very wholesome reading, and deals with the subject of the abuse of medical charity and with the character of the medical services rendered at the dispensaries, in a spirit of candor and fairness that is in sharp contrast with the tone of the reports from other dispensaries. After comparing the increase in the number of patients during the past year with the increase in the population, it says: "It is difficult to escape the conclusion that more and more people are using dispensaries. To relieve actual distress we should be zealous, but to do it with the minimum amount of demoralization to the applicants should ever be our aim. Getting something for nothing is demoralizing, whether it be food, clothing, or drugs. A falling-off in these yearly statistics might speak well for the health of the people, or for their independence, or self-respect; it would not necessarily imply poor dispensary management. Real dispensary progress is shown by increased

efficiency, improved apparatus, and greater skill and promptness, not necessarily by enlarged statistics." If other dispensary managers would act upon the fair principles here laid down, the work of the physicians would be much more carefully and skilfully performed, and both the physicians and the patients would be benefited thereby.

PATENT MEDICINES.

To the Editor of THE MEDICAL NEWS,

SIR: I have read with interest Dr. Cowan's letter entitled "Patent Medicines, Quackery, etc." I would like to ask, How will the patent medicine craze ever be stamped out of existence if reputable physicians continue to prescribe the preparations? It is only a few years ago that a physician in this State compounded remedies such as are sold everywhere and published the formulæ. He was expelled from the County Society to which he belonged. To-day the profession is importuned by firms selling such compounds as antikamnia. These firms refuse to divulge the formulæ, yet physicians prescribe this and many similar preparations. I say, *Down with secret formulæ in the profession!*

Truly yours, GEO. F. REIPER, M.D.

LA FAYETTE, IND., JULY 7, 1891.

NEWS ITEMS.

Hebra.—On Sunday, June 14th, a bust of the great dermatologist, Ferdinand v. Hebra, was unveiled at Vienna. An address was delivered by Professor Kaposi.

Ottokar Chiara has been made Professor Extraordinary of Laryngoscopy and Rhinoscopy at the University of Vienna.

Carl Wilhelm v. Naegeli.—On the 8th of May, Nägeli, the Professor of Botany at the University of Munich, celebrated the fiftieth anniversary of his attainment of the doctorate; on the 10th he was dead. Nägeli was a distinguished botanist and biologist. His body was cremated at Zurich.

A Memorial to Matthews Duncan.—It has been proposed by the friends and pupils of the late Matthews Duncan to perpetuate the memory of the great obstetrician by founding at St. Bartholomew's Hospital a Matthews Duncan medal or prize in obstetrics or gynecology, and the erection of a bust, to cost from $6000 to $7000.

Henry Gawen Sutton, M.B. Lond., F.R.C.P.—In the death of Dr. Sutton, at the premature age of fifty-five, not only the English, but the entire medical profession has suffered a profound loss. Dr. Sutton was especially well known for his work in the department of clinical pathology, and as clinician and pathologist occupied positions at Guy's and at the London Hospital.

Koranyi.—In commemoration of the twenty-fifth anniversary of his accession to the professorship, Korányi, of Budapest, made an endowment of 2000 gulden ($850), the interest of which for three years should constitute a prize to be awarded for the best medical work published during that time by one of the assistants at the University.

Handwriting in Prescriptions.—It is stated that the Austrian Minister of the Interior has recently issued an ordinance that the burgomasters of all communes must exercise strict supervision over the medical men practising within their jurisdiction in the matter of legibility of prescriptions. They are charged to see that every prescription is clearly and legibly written in all its parts, so that there may be no doubt as to the remedy, the dose, or the signature.

The Society of Hypnology will meet at Paris, July 20, under the presidency of Dr. Dumontpallier. Measures will be taken for the organization of a second Congress of Hypnotism, to be held in 1892. Among the subjects proposed for discussion are the following: The Relations of Hysteria to Hypnotism; Criminal Suggestions and Penal Responsibility; The Influence of Maternal Impressions on the Fœtus.

Medical Congress in Cuba.—A medical congress will be held in Cuba in 1892. The following subjects will be presented for discussion: Topography and Medical Statistics in Some One Locality in the Island of Cuba; Etiology, Prophylaxis and Treatment of Yellow Fever; Pathology of the Liver in Hot Climates; Is Malaria the Cause of the Malignity of Fevers in Havana? Scheme for the Improvement of the Sanitary Condition of Havana.

The American Public Health Association, constituted of representatives of the United States of America, the Dominion of Canada and the Republic of Mexico, will hold its nineteenth annual meeting at Kansas City, Missouri, October 20, 21, 22, 23, 1891. The following subjects will be considered: 1. Sanitary Construction in House Architecture; (*a*) Heating; (*b*) Lighting; (*c*) Drainage; (*d*) Ventilation. 2. Railroad Sanitation. 3. Meat-supplies. 4. Milk-supplies of Cities. 5. Arsenical Papers and Fabrics. 6. Isolation-hospitals for Infectious Diseases in Cities. 7. Papers upon any of the subjects upon which special committees have been appointed. 8. Papers on miscellaneous sanitary and hygienic subjects.

The Koch Institute.—The clinical section of the new institute for infectious diseases at Berlin is about completed. The buildings comprise seven pavilions, with accomdations for 108 patients, and two for the medical officers and attendants. There is also a small lecture-room, with seats for fifty. The internal arrangements of the scientific section are already so far advanced that it will be ready for use at no distant date. Dr. Richard Pfeiffer, formerly Professor Koch's first assistant, will have charge of the scientific section, and it is probable that Professor Ludwig Brieger will be appointed head of the clinical department. Professor Koch himself will receive a salary of 20,000 marks ($5000) and Drs. Pfeiffer and Brieger 6000 marks ($1500) each.

Syphilis Legislation.—At the last session of the Massachusetts Legislature the following Act was passed and subsequently approved by the governor:

"SECTION 1. Any person who is confined in, or is an inmate of, any State penal or charitable institution, a common jail, house of correction or municipal or town

almshouse, who shall have the disease known as syphilis, shall at once be placed under proper medical treatment for the cure of such disease, and when in the opinion of the attending physician it is necessary for the proper treatment thereof, or that such disease is contagious, so as to be dangerous to the health and safety of the other prisoners or inmates in such institution, the persons under treatment shall be isolated from such other prisoners or inmates until the contagious stage of such disease has passed, or until the time when in the opinion of the attending physician such isolation is unnecessary.

"SECT. 2. When at the expiration of the sentence of any person who is confined in, or is an inmate of, any of the institutions named in Section 1 of this Act, such person shall then have the disease known as syphilis in its contagious or infectious symptoms, or in the opinion of the attending physician of such institution, or of such physician as the authorities thereof may consult, would cause the discharge of such person to be dangerous to public health and safety, such person shall be placed under proper medical treatment, and kept and suitably cared for as provided in Section 1 of this Act, in the institution where he has been confined, until such time as in the opinion of the attending physician such contagious and infectious symptoms shall have disappeared, and the discharge of the patient shall not endanger the public health. The expense of his support not exceeding three dollars and fifty cents a week shall be paid by the city or town where he has a legal settlement, after notice to the overseers of the poor of such city or town, or, if he is a State pauper, after notice to the State Board of Lunacy and Charity, of the expiration of his sentence, and of his condition."—*Boston Medical and Surgical Journal*, July 2, 1891.

Prohibition Medical Congress.—A medical congress was held at Prohibition Park, Staten Island, July 15 and 16, 1891. Dr. N. S. Davis, of Chicago, presided and delivered an address. The following subjects were discussed: The Physiological Relation of Alcohol to Food, by Dr. William H. Porter, of New York; Dr. Elisha Cheny, of Boston; Dr. Leslie E. Keeley, of Dwight, Ill. Some of the Effects of Alcohol on the Brain, by Axel Gustafson, late of London, England; Dr. N. Roe Bradner, of Philadelphia. Drunkenness a Disease: its Remedy by Scientific Means, by Dr. T. D. Crothers, of New Haven. Can a Physician Practise Medicine without Alcohol? and if so, What Shall be the Substitute? by Dr. C. Gilbert Wheeler, of Chicago; Dr. F. O. Broady, of Chicago; Dr. James Wood, of New York. The Effect upon Longevity of the Moderate Use of Alcoholic Liquors, by Dr. M. L. Holbrook, of New York. Does the Habit of Moderate Drinking in a Patient Increase the Danger when Attacked by Disease? by Dr. L. M. Green, of Wilmington, Ohio. Climatic Influences as Related to Inebriety, by Dr. E. P. Thwing, of Brooklyn, N. Y. The Normal Expenditure, Resources and Maintenance of the Human Economy, Physiologically and Chemically Considered, by Dr. J. Hartmann, of New York. What are the Effects of Alcohol upon the Physical, Chemical and Vital Properties of the Animal Tissues and Fluids? by Dr. Henry Clay Paddock, of New York; Dr. W. F. Pechumen, of Detroit; Dr. Ephraim Cutter, of New York. In What Ways may a Physician Effectively Help to Stay the Ravages of Intemperance? by Dr. R. H. Thomas, of Baltimore; Dr. Henry A. Pooler, of New York; Dr. Fred. Wooster Owen, of Morristown, N. J.; Dr. John Blackmer, of Springfield, Mass. Ammonia vs. Alcohol in Pneumonia, by Dr. George D Dowkontt, of New York. Personal Observation of the Effects of Alcohol in Producing Crime Among Women, by Dr. Lucy M. Hall, of Brooklyn, N. Y. Is Alcohol a Poison? If so, Should it Ever be Taken into the System except under the Direction of a Medical Adviser? by Dr. William C. Wile, of Danbury, Conn.; Dr. Henry Carver, of New York. Does the Moderate Use of Fermented Liquors tend to Injure the Body and Brain? by Dr. Edward C. Mann, of New York; Dr. Henry S. Drayton, of New York. The Use and Abuse of Alcohol as a Medicine, by Dr. Henry C. Houghton, of New York; Dr. H. Bedell Crane, of Newark, N. J. The Woman Doctor: Her Place and Work, by Mrs. Isabella M. Rankine, of Brooklyn, N. Y.; Dr. Sarah H. Morris, of Buffalo, N. Y. The Responsibility of the Medical Profession in Prescribing Alcohol, and their Duty in the Matter of Reform, by Dr. Morris, of Texas. The Use of Alcohol: First as Medicine, Second as a Beverage, by Dr. N. S. Roberts, of New York. Do Alcoholic Beverages Aid Digestion, and Assist in the Assimilation of Food? by Dr. I. N. Quimby, of Jersey City, N. J. The Hereditary Effect of Alcoholism, by Dr. John Francis Burns, of Fort Hamilton, N. Y.; Dr. Henry G. Hanchett, of New York. The Relations of Alcohol and of Heat to the Nervous Centres, by Dr. T. S. Lambert, of New York. The National Temperance Hospital at Chicago; the Results Noted of the Exclusion of Alcohol in the Treatment of Diseases, by Dr. C. G. Davis, of Chicago. The Latest Investigations of the Effects of Alcohol on the Heart, by Dr. David Wark, of New York. What is the Best Medical Treatment for Alcoholism? by Dr. N. L. North, of Brooklyn, N. Y.; Dr. C. H. Shepard, of Brooklyn, N. Y. An illustrated address will also be delivered by Dr. C. Gilbert Wheeler, of Chicago.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 7 TO JULY 13, 1891.

COCHRAN, JOHN J., *Assistant Surgeon.*—Leave of absence on surgeon's certificate of disability extended three months.

BANISTER, W. B., *Assistant Surgeon.*—Granted leave of absence for fourteen days.

IRWIN, BERNARD J. D., *Surgeon.*—Relieved from duty at St. Louis, Mo., and ordered to Chicago, Ill., for duty as Medical Director, Department of the Missouri.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 11, 1891.

BOYD, ROBERT, *Assistant Surgeon.*—Ordered to the U. S. Receiving-ship "Dale," Washington, D. C.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

PROBLEMS IN SURGERY.[1]

BY OSCAR H. ALLIS, M.D.,

SURGEON TO THE PRESBYTERIAN HOSPITAL, PHILADELPHIA; FELLOW OF THE AMERICAN SURGICAL ASSOCIATION.

PROBLEM I. *A man in fine health, thirty years of age, falls before a moving railroad train and has his arm crushed and severed from the body just below the shoulder. Seen an hour after the accident, he has a fairly good pulse, is perfectly conscious, has "reacted" well, has a good moral and physical history. Shall the surgeon proceed to amputate?*—The simple problem of shock is to be met. This is a most important question. It has been studied critically for a century. I cannot enter upon a discussion of it now. I can only state my own impressions, experience and practice, and leave the subject undefended. My answer is, *No.* I care not how soon after a railroad accident the patient is seen, there are elements common to all cases that cannot be estimated by any instrument of precision. Who can estimate the agony of the man as he falls, as it were, into the jaws of death? Who can estimate the shock, even if he escape bodily harm? Who can estimate the pain produced in the severance of the limb at a point so near the trunk? Add to this the unavoidable loss of blood—and I need no more to convince me that the man, with his "fair pulse" and "good reaction," is yet in too profound a state of shock to add to it. It were better by far to carefully wash the lacerated stump with warm bichloride solution, to dress it with as much care as if amputated, to leave the man for at least twelve hours, and secure for him the best of all restoratives, sleep—and even then do not amputate simply because he has had *time* to react. As there is no means of estimating shock, so there are no criteria by which we can estimate its subsidence. One of the blessings of modern surgical methods is that a lacerated stump can be kept uncontaminated for days, and the amputation suffer nothing by the delay.

Men for ages have taught, and are still teaching, that if you find a man immediately after an accident, even though he be in a state of profound shock, the amputation adds nothing to the magnitude of the shock nor danger to the patient. To this I have simply to say that if you could drag the poor fellow from under the wheels of the car, and place him immediately upon the amputating table, with everything in readiness, such an act would be wanting in good common sense. In such a case I would by all means dress the wound with scrupulous care and defer amputation for at least a day. Upon this point few will agree with me. Let those who hold a contrary opinion stop and reflect upon the number that have died upon the operating-table, or within six hours after amputation, and, if their experience is like my own, they will recall cases in which their judgment was at fault, and that the increment of shock from the amputation was sufficient to turn the scale adversely. There were formerly arguments against delay that do not exist now. The advances in surgical methods make possible, and often of vital importance, the delays of which I speak.

PROBLEM II. *There is an injury to the foot of such a nature that a portion of the tarsus can be saved. Shall we select a Chopart, or a Pirogoff?*—The question is as to the point of amputation. It is an axiom in surgery that when a limb is injured one should save all he can. Were I to lay down a rule I would base it on the function of the limb. The function of the upper extremities is *prehension*, hence save all you can. A finger or half a finger may be of priceless value. The function of the lower extremities is *locomotion*, hence the operation should be adopted that will yield the best results. Upon this head we can learn much from the makers of artificial legs. One that I consulted, alluding to Chopart's and Pirogoff's operations, said: "Amputations about the ankle always make poor walkers. Every leg-maker will tell you so." Another, referring to the same class of amputations, said that in such cases he was able to fit limbs, but that the best walkers were those that had a few inches below the knee. The testimony of the patients themselves is of great value. Men who can hunt, mount the saddle, run up and down stairs, hardly miss the amputated part; but this cannot be said of those in the case of whom the Chopart or the Pirogoff operation has been performed. Such men can walk slowly and conceal their defects, but they cannot walk fast or run without a decided limp. Upon this subject I fully indorse the sentiments of Dr. Mordecai Price, expressed in a valuable contribution to surgery.[1] The same criticism applies

[1] Being the Annual Address in Surgery read before the Medical Society of the State of Pennsylvania, June 4, 1891.

[1] Trans. of the Philadelphia County Medical Society, 1889.

to amputation through the knee-joint. The rule, "Save all you can," has in this connection, as in others, been of great detriment. Leg-makers (and leg-wearers confirm their statement) say, Never amputate through the joint unless you saw off the condyles; but it is far better to amputate just above the condyles. Don't amputate through the joint; go *above or below it*.

PROBLEM III. *Shall we use ligatures in our amputations?*—Ambroise Paré introduced the ligature and surgeons have ever since been trying to do without it. Acupressure had its brief hour of notoriety: torsion has shown itself to be safe, even upon the axillary and femoral arteries. But the ligature triumphs—not that of its immortal author, large, clumsy, and septic, with one end sticking out of the wound, but the ligature of the finest, choicest, strongest sterilized silk, or animal fibre, cut short, and allowed to remain. For the smaller vessels the hæmostatic forceps suffices. He who introduced these should have a monument beside that of Ambroise Paré. Other questions, such as those pertaining to fractures, to drainage, suturing, dressing and re-dressing, all present themselves, but I cannot delay to present them.

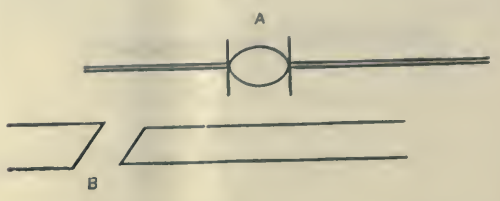
PROBLEM IV. *A woman, seventy-five years old, has fallen and fractured the neck of the femur. What shall be the treatment?*—The conditions of the problem are clear and distinct, yet what differing results are obtained! One will apply weights, demand absolute rest, reap a harvest of bedsores—and an early death. Another, following the directions of Sir Astley Cooper, will disregard the fracture, treat the woman, get her out of bed in a week, if she will bear it, with a good useful limb to reward him for his pains.

The prevailing deformity in fractures at the upper third of the femur, exclusive of the neck, presents a striking uniformity; in many cases the patient remains a cripple for life. Two problems present themselves: Why is the man with a strongly united bone, lame, and why do we remain satisfied with a mode of treatment that cannot fail to produce deformity?

Up to this point I have selected every-day accidents to illustrate the problems that present themselves. The answers are best known to the medical profession. I wish now to direct attention to a line of work that should engage our serious attention, and to problems that, as a profession, we have disregarded, or upon the solution of which we have looked as impossible.

PROBLEM V. *A child falls and injures its elbow; a fracture is discovered. The bone unites, but the forearm wastes; the fingers are contracted; there is every evidence of a nerve lesion associated with the injury. Six months wear away; massage and electricity are employed without avail. What shall be done?*—I have seen four such cases. Erichsen also reports some of the same kind. I have in three instances advised a mode of treatment that seems to me rational, but I have never been permitted to carry it out. I would cut down upon the nerve and excise the cicatrix (A, Fig. 1), and measure the

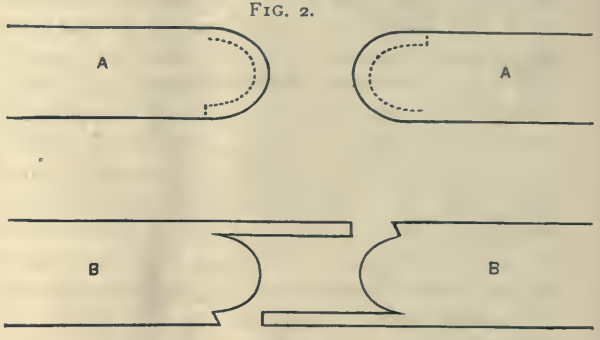
FIG. 1.



length of nerve removed. If the gap were considerable, say an inch, I would remove the same length of bone from the humerus (B) at a point some distance above, reunite the humerus, suture the nerve, and close the wound.

PROBLEM VI. *Both bones of the leg are broken; the fibula unites; the tibia fails to unite. How shall we proceed?*—It is not a difficult matter to bring about union of the tibia by removing a section of the fibula; but the real difficulty lies in lengthening

FIG. 2.



the tibia. Phelps has made an honest effort at lengthening the bones under conditions somewhat similar to those stated. The bone-dowel has been tried for the same purpose, and decalcified bone chips have been implanted in the hope of inducing recalcification. To lengthen bone, to restore a lost joint, suggests problems that it seems hard to think are beyond the skill of man.

My suggestion is as follows: Let A, A, Fig. 2, represent the ends of the unuited tibia. If the periosteum, with sufficient superimposed connective tissue, be dissected from A, A, as represented in B, B, and the intervening space be filled with bone chips, it is possible that the tibia could in this way be reproduced.

PROBLEM VI. *The surgeon, in operating for the radical cure of hernia, incautiously cuts the vas deferens. Shall he suture the divided ends?*—Here is a subject that may well engage attention. The lumen of the spermatic canal is very small. Unless perfect

approximation be secured, there must supervene a mechanical obstacle to its ever again acting as a duct.

Fig. 3 illustrates how any defect in approximation would be fatal to its function. The subject presents a problem worthy of careful study.

Fig. 3.

The most important tubular structures in the body are the arteries. It is sad to think that the division of the femoral artery, by a stab from a penknife, may prove fatal to life or limb. How helpless a surgeon feels, that he must at times amputate a limb to save life, when the only injury is that before mentioned. Must we always stop where we are? Must the retraction and contraction of arteries, the tendency to clotting, the secondary hemorrhage and tendency to aneurism, ever remain bars to progress in this direction?

In the ordinary phlegmonous abscess we note its maturing in a fortnight, its spontaneous rupture and rapid healing. There is a single point in this that I desire to notice, viz., its rapid, spontaneous cure. This is due to its collapsing. The abscess forms in soft tissues that render collapse certain. Abscesses in bone cannot heal by a collapse of their walls: they always pursue a tedious course.

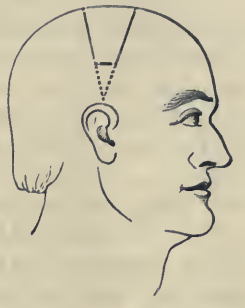
In connection with the principle of the collapse of an abscess let me consider an injury of the skull resulting in the formation of an abscess.

Problem VII. *A blow is struck or a wound inflicted upon the skull; a cerebral abscess forms; pus is found in the wound or upon trephining. What is the proper treatment?*—Can such an abscess heal by collapse of its walls? Certainly not. Such cases are far too often fatal. Pus tends to find a dependent outlet when it cannot readily flow off. What shall be done? I would suggest the removal of a sufficient amount of the skull to permit the dura to fall in with approximation of the abscess walls. This is illustrated in Fig. 4.

Fig. 4.

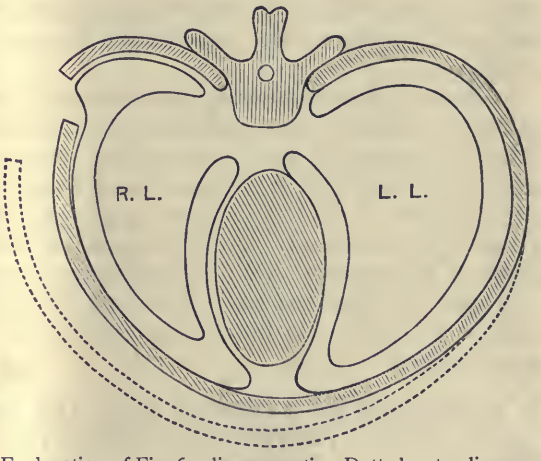
In hydrocephalus we have an analogous condition. To aspirate ventricular fluid contained in a closed, bony cavity, is likely to do more harm than good. In hydrocephalus both ventricles are usually filled; there is symmetrical dilatation; there should be a provision for symmetrical contraction; hence the plan of the removal of a portion of the vault of the skull, extending through both parietals. This is illustrated in Fig. 5. It is possible to remove the bone from the sinus and not wound the latter. Then gentle, symmetrical compression, together with constitutional remedies, would hold out a prospect of return to normal conditions.

Fig. 5.



There is still another field, a most important one, in which the lesson from the collapse of an abscess suggests a remedy. I allude to pulmonary tuberculosis. Why this disease is not self-limiting in pulmonary tissue, as it is in the head of the femur, is not to be explained by the nature of the disease itself. The tuberculous joint can throw off the disease. In pulmonary tuberculosis the system makes a most desperate effort to accomplish the same end, but fails. Nature gives us a hint as to the way in

Fig. 6.



Explanation of Fig. 6—diagrammatic: Dotted outer lines represent the contour of chest before the removal of part of a rib. The deeper, dark lines show how much the chest has sunken in. The greater shrinkage is to be found on the side from which the section of rib has been taken, as will be seen by comparing the two lungs.

which we should proceed. Who that has made an autopsy in a case of advanced phthisis has found the pleura? What has become of it? Nature has glued its two surfaces together. The lung is fastened to the chest-wall. Nature puts forth all her energy to cause collapse of the chest-cage. She succeeds but in part. The sunken chest is an illustration of Nature's mode of causing shrinkage of the abscesses in order that she may effect a cure. Why not follow this hint and seek to give relief by the retraction that would follow a resection of the ribs?

I would make the following suggestions:

(1) At what point make the resection? As near the angle of the rib as possible, *i. e.*, in the lateral or postero-lateral aspect of the chest. A glance at Fig. 6 represents the short portion of the rib unaffected by the section. This, I think, will unquestionably be the result. The long part of the rib is now attached only to the vertebral column through the sternum and the corresponding rib of the opposite side. It becomes a long lever, and can be most readily acted upon by atmospheric pressure.

(2) How much of each rib should be resected? At least two inches, possibly three. I say at least two, for no possibility should be afforded for the bone to be reproduced. To this end the periosteum should be removed with the bone. A cicatricial fibrous band will form that will answer every purpose.

(3) How many ribs should be resected? At the very least four, and these should be the longest. A resection of the fifth, sixth, seventh and eighth ribs would remove much of the resistance of the thoracic cage, and permit a very considerable degree of retraction.

As to the mode of performing the operation I have nothing to suggest. The ease with which in pyothorax the resection is done is striking, and the great value of resections in this disease are now matters of surgical history. So, too, in regard to the best time to make the resection. I would suggest the early stage. Certainly less could be hoped from so severe a measure in advanced cases, with both lungs involved, than when the disease was confined to a single lung.

OBSERVATIONS ON TUBERCULOSIS; AND THE DIAGNOSTIC VALUE OF THE TUBERCLE BACILLUS.[1]

BY HENRY SEWALL, M.D., PH.D.,
OF DENVER, COL.

THERE is probably not in the whole nosology a more sharply defined disease than tuberculosis. The ideal of scientific classification is approached when the structural changes of a disease can be used to guide and determine the procedures of surgical art. Thus, hesitating to perform a radical operation, a surgeon opens a cavity suspected of being tuberculous, and sends a portion of the diseased tissue to the adjoining pathological laboratory; in ten minutes word is returned that the tissue is tuberculous, and all doubt and hesitation on the part of the operator are removed.

Darwin and others have shown that animals in their evolution from ancestral forms have diverged in groups that, though remaining distinct and well defined at their centres, may be inextricably blended at their adjoining borders, making a rigid classification impossible. In the same way in diseases that in many cases are but the effects of developmental life—*i. e.*, of germs—there is often doubt as to classification when the symptoms and lesions are common to different disorders. There is thus a broad borderland surrounding the type of tuberculosis in which are represented maladies the nature of which is in dispute. According to Welch, there are many authorities that consider it proved that scrofula is but a peculiar manifestation of tuberculosis, although probably a great majority of medical thinkers still consider the question *sub judice*. Again, evidence has abundantly accumulated for the opinion that lupus is simply a tuberculosis of the skin; yet so eminent an authority as Jonathan Hutchinson, in a recent discourse, after throwing doubt upon the bacillary origin of lupus, said: "The result of Koch's injection treatment may possibly force us to believe that there is something about lupus that connects it far more closely with tuberculosis than I have admitted." Then, again, there is the oft-fought battle over the relationship of tuberculosis and pulmonary phthisis. I think it may be said, without fear of contradiction, that an immense majority of those competent to discuss the question hold that, with certain definite exceptions, phthisis and tuberculosis of the lungs are coextensive terms; in other words, the "unity of phthisis" has been established. But certain authorities worthy of a hearing (for example, Gibbes and Shurly) insist that there are two pulmonary affections anatomically and clinically nearly identical, but one of them a specific germ-disease, the other not so. Universal acceptance of any conclusions pertaining to the subjects thus far outlined must be left for the wider knowledge of future decades.

To-day we may rest secure in the belief that there is a disease called tuberculosis, that has definite clinical and anatomical features, and that is characterized by the invariable occurrence of a certain microscopic parasite known as the "tubercle bacillus."

In a work that ranks with Harvey's demonstration of the circulation of the blood, Robert Koch, just nine years ago, proved that the tubercle bacillus is the cause, and not simply the accompaniment, of

[1] Read before the Medical Society at Denver, April 21, 1891.

tuberculosis; and incidentally he proved that tuberculosis is an infectious disease, the agent of infection being the bacillus itself, transmitted from one individual to another. Koch's work has withstood every assault that adverse ingenuity could bring to bear upon it. Koch's conclusions were derived from experimental observations on the lower animals, which proved, as we have said, the bacillary origin and infectiousness of tuberculosis.

But in the case of our human brother it is, for obvious reasons, difficult to reach early and safe conclusions on these subjects, and I have been led to believe that only a comparatively small minority of the medical profession admits the infectiousness of tuberculosis in man. Still, anyone may find abundant evidence that tuberculosis is transmissible, and that, moreover, the avenues for the reception of the virus—*i. e.*, the bacillus—are the air-passages, the alimentary canal, and open wounds. In pulmonary phthisis the agent of infection is expelled from the body, so far as known, only in the expectorated sputum.

It may not be out of place to rehearse a few of the many observations that have recently been made with reference to these points. Cornet, in his remarkable work on the infectiousness of tuberculosis, found that the air expired from the lungs of phthisical subjects was never infectious, but he found that the dust wiped from the wall at the back of the beds of such patients produced tuberculosis in guinea-pigs inoculated with it. No forms of bacteria rise from a still, moist surface; it is the drying of the sputa that allows these minute organisms to be wafted about as impalpable dust. Cornet wiped the dust from the walls of hospital-wards and waiting-rooms and injected the various specimens into rabbits and guinea-pigs. The results were negative, except in those cases wherein the dust came from rooms inhabited by tuberculous patients that were careless of their sputa; in such cases tuberculosis was often produced. Another class of facts is as follows: The convent of Frauen Chemsee is on an island of 300 inhabitants. Since the beginning of this century there have always been a few deaths from phthisis among the inhabitants, but never more than seven in ten years. Not until 1860 had a death from tuberculosis occurred in the convent. In each following decade, however, there were, among the from twenty to forty nuns, two deaths from tuberculosis, and in the last decade there were eleven sisters ill with the disease. Many similar observations might be presented illustrating the communicability of the disease. Again, Cornet has gathered the vital statistics of the Catholic orders of nurses in Prussia for the last twenty-five years. These institutions contain a yearly average of 4028 persons, who usually enter at the age of twenty-five, after a medical examination and having been certified as healthy. But the average age at death was 37.27 years, or ten years below the normal. Three-quarters of these deaths were from tuberculosis. Avendario has reported a case of tuberculous infection of a boil in a patient placed in the same hospital ward with consumptives; parts of one lung were secondarily infiltrated. It has been found that when an extract of a pure culture of tubercle-bacilli is fed to animals, the bacilli penetrate the epithelium of the alimentary canal and produce general infection. A dilution of tuberculous sputum of 1:400,000, injected into guinea-pigs, still produces tuberculosis. Careful statistical enumeration also shows that tuberculosis, or, perhaps better, a disease having the physical signs and clinical history of phthisis, is responsible for one-seventh of the deaths from all causes, while during the productive period of life one-third of all deaths may be attributed to it.

Whatever theories as to the unity or duality of phthisis may be held, it is hardly to be doubted that a vast majority of the cases are of bacillary origin. Ever since the demonstration of the tubercle bacillus in 1882, investigators all over the world have been on the lookout for evidence to invalidate the doctrine of the germ origin of the disease. Yet I find in volumes v. to vii. of the *Centralblatt für Bacteriologie*, in which is gathered the current literature of bacteriology for the years from 1888 to 1890, but two recorded cases of death from disease presenting the clinical history and post-mortem appearances of pulmonary phthisis, but in which it was not possible to demonstrate microscopically the presence of tubercle bacilli. Some seven or eight years ago, E. L. Trudeau published the clinical history of a similar case, and Gibbes appears to have seen several.

It should be noted that the search for bacilli in a section of tissue or a film of sputum under the microscope is similar to the proverbial hunting for needles in a haystack; unless the needles be fairly numerous, it is highly probable that they will be overlooked. Thus the surgical pathologist does not depend on microscopical examination to determine the tuberculous character of a diseased joint, but he withdraws a portion of the tissue or fluid therefrom, places it in a nutritive medium favorable to the growth and multiplication of the bacilli, and then inoculates a rabbit or guinea-pig with the culture, and watches for the development of tuberculosis in the animal. I have known the two or three bacilli on a slide containing a film of tuberculous sputum to be overlooked, though carefully searched for by more than one observer. Therefore, negative microscopic evidence as to the presence of bacilli in sputum or tissue must be received with caution.

Let us now briefly consider the morphological and vital characters of the tubercle bacillus which, I have

presumed to be the etiological factor in the disease. The size and form of the bacilli in general are variable, but there is something characteristic in each individual that the trained eye readily distinguishes. The bacillus tuberculosis is one of the minutest of the rod bacteria. The length of the single rods varies from one-quarter to three-quarters of the diameter of a human red blood-corpuscle; the majority have a length of from 3 μ to 4 μ, the width of the microbe being but one-fifth to one-sixth the length. The bacillus may appear in the form of a rod that is either very short or long, or of a long rod apparenly made up of short joints; or the protoplasm of the rod may be aggregated into minute spores. But it is the reaction to staining reagents that distinguishes the tubercle bacillus from all other bacteria except the bacillus of leprosy. It absorbs dyes much more slowly and gives them up much more reluctantly than do other bacteria; it is on account of this micro-chemical reaction that it is possible to distinguish the tubercle bacillus in a medium containing any number of other bacteria.

During the past year, while resident physician at the Adirondack Cottage Sanitarium for the Cure of Phthisis, I had valuable opportunities for studying some of the little-known factors in the history of tuberculosis. One principal object of my observations was, if possible, to discover some constant relation between the microscopical and chemical characters of the tubercle bacilli, as demonstrated in the sputum—such as their size, shape, number, and staining reactions, and the clinical history of the patients as represented by physical and rational signs showing their general condition of vitality. According to their signs and symptoms, patients were divided into four classes: 1, those that were undoubtedly on the road to recovery; 2, those that were simply holding their own; 3, those the condition of whom was doubtful; and 4, those that were undoubtedly failing. I had the pain of finding few positive replies to the questions to which I sought answers, still the results were not altogether barren. Like other observers, I found but little correspondence between the gravity of the clinical symptoms or signs and the number of bacilli in the expectoration. In some of the worst cases, the bacilli were comparatively few, though they were constantly least numerous in patients that seemed very near recovery; the microbes were apparently most numerous in the sputum of those invalids with extensive signs of pulmonary trouble, but the course of the disease of whom had become arrested. There seemed a tolerably well-marked connection between the size and shape of the individual bacilli and the virulence of the disease. As had been previously suggested to me by Dr. Trudeau, of Saranac Lake, Director of the Sanitarium, I found that the very short straight rod-forms generally corresponded to cases that were manifestly running to a fatal termination. I also came to the conclusion that the long forms, made up of short rods or joints, indicated the same serious vital condition; while the long, smooth, homogeneous rods of straight or curved outline were, in general, characteristic of cases in excellent physiological condition.

The sputa of some patients were remarkable in the richness of spore-formation in the bacilli; this appeared to be particularly marked in old cases that were holding their own well against the disease.

It is a familiar fact that bacteria of any kind, when stained by aniline dyes, rapidly lose their color on the addition of an acid, and it is probably commonly believed that the distinctive micro-chemical character of the tubercle bacillus is a resistance to this decolorizing action of acids, the explanation being the slow diffusion of stain and acid through the body of the bacillus. This belief and explanation cannot be correct, for I found that when the stained bacilli were treated with acid while watched under the microscope, they would almost immediately lose their color as did the non-pathogenic forms. But when the acid was in turn washed away by irrigation with water, the color would return to the tubercle bacilli, provided the action of the acid had not been too long continued. The same fact may be demonstrated in regard to the epidermis of one's hand: a little eosin solution stains it deeply; acid poured on takes the color out, but this to some extent returns when the acid is washed away with water. Now if, as the facts seem to demonstrate, the vitality of the tubercle bacillus is a variable factor, we might with reason expect that the most virulent forms of bacilli would be present in the worst clinical cases, and the least noxious in those wherein the disease was under control; and, furthermore, we would expect to find the reaction of the bacillary protoplasm to staining dyes to vary with its functional activity or virulence. As a matter of fact, my observations gave reason for the belief that in pure cultures of the tubercle bacilli, when the cultures were fresh and virulent, the stained microbes were more resistant to the action of acids than in the case of similar cultures that had been kept for months and had demonstrably diminished in virulence or had entirely lost it.[1] Correspondingly, though with much less certainty, experiments indicated that in the worst clinical cases the association of staining dye with bacillary protoplasm was more stable than in the milder forms of the disease.

I now come to the all-important question in practical diagnosis. What is the probability of the

[1] For the pure cultures of bacilli I was indebted to the kindness of Dr. Trudeau, to Drs. Councilman and Abbott, of the Johns Hopkins University, and to Prof. Vaughan, of Ann Arbor.

bacillus being demonstrable in the sputa of a given case of tuberculosis? The fact that bacilli are demonstrably present, but owing to their paucity of number are usually overlooked, has already been referred to. It may be admitted, without fear of successful contradiction, that where the bacillus is demonstrated there is tuberculosis. But how far may tuberculosis exist without certain physical signs, or without bacillus-containing sputum? This is an all-important question, for this is the stage of phthisis that is manageable, and there is little doubt that the disease might soon be stamped out if diagnosticated thus early.

For several years I have had under careful observation a case of which I append a brief account:

An athletic man, closely confined to sedentary work for nearly ten years, at the age of thirty, and after some weeks of general malaise, suddenly suffers from hæmoptysis. With care there is apparent recovery, and violent exercise is frequently indulged in and enjoyed. Each succeeding winter, however, brings on a train of distressing subjective symptoms in the form of pleuritic pains and failure of nervous energy. For four years after the hæmoptysis, careful examination of the slight and non-typical expectoration, which was probably not pulmonary in origin, failed to reveal the presence of bacilli. Suddenly, without other symptoms, a slight pulmonary expectoration began, and the presence of tubercle bacilli in the sputa was immediately demonstrated. During all this time, and for three months after the appearance of the bacilli, repeated examinations of the chest by different and competent observers had been made with negative result, except so far as a limited occurrence of those indefinite variations from the typical respiratory murmur that, if considered pathognomonic, would class the great majority of mankind as tuberculous.

Rather suddenly, about four months after the demonstration of bacilli in the sputum, this patient presented manifest moist sounds at both apices, their only precursor having been a slightly prolonged expiration. Only slight loss of weight and deterioration in appearance had marked the course of the disease. There is, I think, good reason for believing that in this patient tuberculous disease antedated the hæmoptysis that occurred four and a half years before the appearance of physical signs in the chest.

Very valuable in this connection are the data recently gathered by a pathologist of New York. His object was to discover whether the tubercle bacillus could be proved to exist in the human body without giving rise to organic disease. He was permitted to make autopsies of persons that had met with sudden death by accident, but who had previously presented no evidence of tuberculous disease. With strictest precautions against contamination, bronchial glands were removed from the subject on the post-mortem table, and extracts from them were injected into living animals. The results were that in a large percentage of cases the animals so treated became tuberculous. Facts like these, aided by a legitimate use of the knowledge we possess concerning the innate protective powers of the living tissues, make it easy to believe that the virus of a disease like tuberculosis may lurk for an indefinite time without objective signs or symptoms, until some untoward change of environment or depression of vitality lights the spark into a blaze that is beyond our power to extinguish.

An exact estimate of the value of sputum examination in the diagnosis of tuberculosis could only be made after careful study of hundreds of phthisical cases kept under observation for months or even years of time. For it cannot be too strongly insisted upon that in a certain percentage of cases the bacilli are in a location unfavorable for expectoration until the pulmonary lesion has taken a special and new direction. Thus, a year ago a woman came to the Sanitarium with manifest physical signs of pulmonary trouble and a personal and family history of tuberculosis. No bacilli were discovered in her sputum. She was dismissed after some months, much improved. To-day she is in Denver; the physical signs have somewhat increased, but still no bacilli are to be found.

The data that I have to record were gathered from observations made at the Adirondack Cottage Sanitarium already mentioned. They include only patients submitted to examination with the definite objects set forth in this paper. The Sanitarium is an institution for the *cure* of phthisis, and so far as possible admission is restricted to patients in the earlier stages of the disease. As a matter of fact, however, humanitarian impulses not infrequently allow a person in an advanced stage of the disease to slip in. However, as there is a strong effort made to allow the entrance of only curable cases, we have here a collection of patients in whom, if a fair proportion of bacilli-holding sputa could be detected, the fact would argue very strongly for the diagnostic value of the microbe. Indeed, so well is the restriction on the admission of cases maintained that it would be difficult for an untrained eye to discover that the sojourners at the Sanitarium are a collection of invalids, so well preserved is their nutrition and general physical condition. The whole number of patients observed with reference to the facts detailed was 72. As to sex, they were just evenly divided. As to age, 17 were 20 years old or under; 37 were from 21 to 30 years of age, and 18 between 31 and 40 years. Of the whole number of patients, 5, or a little less than 7 per cent., claimed to have no expectoration. It is significant that all of these were women, and with one exception their ages ranged

from 25 to 37 years. A certain proportion of the patients expectorated more or less profusely, but microscopic examination, usually several times repeated, failed to discover bacilli in their sputa. This class consisted of 16 persons, or 22 per cent. of the whole number. In all the remaining 51 patients, bacilli were detected with certainty; these form 70.8 per cent. of the number, or more than 75 per cent. of the number expectorating.

An analysis of these cases according to their physical and rational signs is not without interest. Of the 21 cases in which no bacilli were found, all were in excellent condition in regard to nutrition and the enjoyment of life, with the exception of one, who suffered and soon died from intercurrent Bright's disease; the remaining 20 were alive and comparatively well when last heard from. Five of the 21 had rather extensive physical signs, while 9 of the remaining 16 had signs of disease so faintly marked that they could with difficulty be detected. Two of the number whom I found without bacilli were said in times past to have had the microbe demonstrated in their sputa by other observers. Of the 51 patients in whom the bacilli could be demonstrated, 18 were manifestly in a decidedly bad way—in fact, 15 of these, or nearly 30 per cent. of the 51 having bacillary sputa, are known to have died since these records were made. This leads to the conclusion that when phthisis is fatal it is tuberculosis, with tubercle bacilli in the sputum. Twenty-one of the 50 bacilli-expectorators were in a serious clinical condition, but holding their own against the disease, and a large proportion were capable of considerable physical exercise or useful employment. Finally, 12, or more than 23 per cent. of the 51, might be described as in excellent condition, and would be considered healthy persons in any average community. The history of a number of those in this last class would be an interesting exhibition of how in phthisical cases environment may bring about rapid improvement or serious deterioration.

As already remarked, two patients, in the sputa of whom bacilli were wanting, were said previously to have had the bacilli present. During my own observations, lasting over some eight months, I found the bacilli to disappear in but two cases, though slight physical signs still remained, while in two others the germs were found in a second search after having been overlooked on the first occasion.

To sum up, out of 72 cases of pulmonary phthisis, more than 55, or 76 per cent., were in such good general condition that their invalidism would hardly have been noticed in an ordinary community. Tubercle bacilli were demonstrated in the sputa of 51, or 70.8 per cent. of the whole number.

In conclusion, I beg to offer a practical remark with regard to prophylaxis. If we take it as proved, that tuberculosis is infectious, and that the agent of infection is the bacillus contained in the sputum expectorated, it needs no discussion to show that the utmost care must be used to render innocuous the matter expectorated from the lungs of consumptives. It is practically impossible to make the safeguards absolute, for no one can prevent an invalid from expectorating on the street, even though æsthetic impulses may render his presence harmless while indoors; but we may draw comfort from an observation recently made by Koch, and quoted in the *Lancet*, that "direct sunlight quickly killed bacteria—the tubercle bacillus for example. Even daylight produces the same effect, though more slowly. Cultivations of tubercle bacilli, propagated for from five to seven days at a window, died." In this way, it is to be hoped, the germ-laden dust of our streets is providentially looked after. Disease germs, like evil, seem to love darkness. Dr. Gibbes has said that he has inoculated animals with tuberculosis by means of a film of dry sputum that he had kept, if I remember rightly, for two years.

The safe disposition of the sputum of consumptives is a matter of such paramount importance to the welfare of every community that of late years many methods have been devised to this end. Undoubtedly the most thorough system having in view the prevention of infection is that recently proposed, I believe, by a Russian savant, who seriously suggested that every person suffering from pulmonary phthisis be compelled by law to constantly wear suspended around the neck an elaborate form of spit-cup to receive his expectoration, and which should bear to the patient somewhat the same relation that the nose-bag does to the horse's head.

Much ingenuity has been exercised in devising receptacles for the tuberculous expectoration in the form of simple portable cups, or more or less complicated vessels of glass; but beside the patient's æsthetic objection to using them there is the much more cogent difficulty of the uncertainty of completely sterilizing the vessels when out of use. In my opinion, by far the best form of spit-cup is that manufactured from cardboard by the Sanitary Supply Company of New York. The cup is so constructed that it may even be overturned without spilling the contents—a very important feature—and when after a few hours or a day the cup has served its purpose it may be submitted to the action of that most perfect of all disinfectants—fire.

In the Adirondack Sanitarium, guarding the expectoration is carefully insisted on. Patients are warned against swallowing the sputa — probably the usual method of its disposal in polite tuberculous circles; they are cautioned against expectorating in

handkerchiefs, which soon dry and let their dust fly to the winds; and they are forbidden to expectorate from the public veranda; such an act as wilfully expectorating on a floor would be considered hardly less than a crime.

On the other hand, the patient is provided with the small hand spit-cups *ad libitum*, and on the public veranda and in the halls of the Sanitarium much larger paper receptacles of the same pattern are inconspicuously but conveniently placed.

The therapeutics of phthisis embraces a legion of drugs and methods; but to-day, even in the light of the agitation of the past few months, we must agree in believing that only in a system of rigid prophylaxis can we hope to successfully cope with the king of diseases.

BARIUM CHLORIDE FROM A CLINICAL STANDPOINT.

By JAMES STRATTON CARPENTER, M.D.,
of Pottsville, Pa.

Miss K., aged thirty-one years, has been under my treatment for mitral stenosis, which had been so long neglected by a homœopathic practitioner, under the care of whom she had previously been, that all the resultant congestive conditions of the internal organs that are so liable to ensue in the course of an untreated lesion of that character had been produced. Her condition at the time I was first consulted, some six months ago, was as follows: The patient was of slight build, of sallow complexion, with puffiness of the eyelids, and presented a typical, anæmic appearance. Auscultation of the chest yielded negative results. The respiratory murmur was but feebly heard; no râles or other abnormal sounds were elicited; it seemed as if the enfeeblement of the respiratory sound was due to deficient expansive power of the chest, which was narrow and contracted, rather than to any direct diseased condition. The heart's action was rapid, its frequency almost uncountable, with nearly complete absence of the first sound. The heart beat not less than 160 times per minute, while the pulse taken at the wrist was so thready as to be almost indistinguishable. There was heard a presystolic murmur, traceable backward to the angle of the scapula, but loudest at the apex. Among the subjective symptoms, particularly referable to the pulmonary and cardiac circulation, were cough and dyspnœa on the slightest exertion; palpitation, frequent and distressing, occurring independently of exertion; pain of intolerable character, described as lancinating, located in the cardiac area, extending also through the chest antero-posteriorly from sternum to interscapular region. Dyspeptic symptoms were prominent. Renal congestion was shown by frequent micturition, particularly troublesome at night, rhachialgia and scanty secretion. The bowels were inactive. The entire system thus loudly attested to some fundamental disturbance that, under "symptomatic treatment," had been altogether undiscovered and unprovided for.

Under a strict dietary, and with medical treatment, a pronounced improvement was made in the gastric and renal conditions; irritability was altogether overcome; the puffiness under the eyes disappeared; the color improved; and a marked lessening of the many nervous symptoms which had been so distressing to the patient was effected. The unsatisfactory results, however, from remedies directed to the regulation of the cardiac action was highly disappointing. While the relief of the dyspeptic phenomena obtained from a milk diet faithfully adhered to for several months had, it is true, lessened the frequency of the attacks of palpitation and the intensity of pain dependent upon the catarrhal gastritis, but little influence was exerted upon the cardiac condition. The pulse continued at just as rapid a rate and remained just as thready, notwithstanding the administration of digitalis, persisted in for some weeks. Tincture of strophanthus, in increasing doses, was substituted, but in no way lessened the unruly heart-action, which may be best illustrated by recalling the experiment of section of the inhibitory nerve of a rabbit's heart, yearly demonstrated before the medical classes by the professors of physiology; so, in this case, it seemed a clear instance of "runaway heart," that neither of the two recognized cardiac medicines could bring under control. These remedies having so utterly failed in influencing the disordered action of the heart, where was there hope of obtaining a remedy through the general system? The failure of strychnine to influence in any degree the cardiac ganglia seemed to close the door against further trial in that direction.

At this time when, in lieu of a better drug, I had again resorted to digitalis, it occurred to me to make trial of the chloride of barium, which had been highly lauded in The Medical News, by Dr. Hobart A. Hare, as a cardiac medicine, and as an excellent substitute for digitalis, by its action increasing the diastolic pause while it strengthened the systole—the very object sought in the present instance. I had employed the salt once before in a case of irritable heart of purely functional character, administering it in two-grain doses, three times a day, without the slightest effect upon the distressing palpitation from which the young lady suffered. In a second case it was administered in five-grain doses, three times a day, the patient being an old man in the second stage of pneumonitis; in him heart failure was threatening. Not the least untoward effect upon the system was noted, the irregular heart-action being brought under full control.

In the present case I considered myself perfectly safe in commencing the use of the chloride in the dose of gr. 1.6, three times a day, but my experience was such that in future I shall consider it a far safer plan to begin with a much smaller dose, a half fluidrachm of a one per cent. solution, as recommended by Professor Hare, as being the more prudent method of administration, as the sequel shows.

About ten o'clock in the evening of March 14th, I was hurriedly summoned to my patient, with the message that "she had been taken very sick." The barium chloride had been begun that day, and, as the message was so imperative, I permitted no time to be lost in answering the summons. On entering

the sick-room I found my patient presenting most alarming symptoms, the result of a gastro-enteritis, which, with all the distressing features, was more than eclipsed by the terribly depressant effects of the barium salt upon the heart. The pulse was scarcely definable at the wrist, coming in a feeble intermittent wave, and recording but 26 beats per minute! Auscultation revealed the heart acting tumultuously, with a heaving character, at if there were not enough blood obtainable to keep it in motion; its efforts to contract upon the almost fatally diminished volume of life-fluid were as 4:1 in the ratio of heart-action to radial pulsation. The patient presented a ghastly appearance. The face was deathly pale; the eyes were sunken, the lips of purplish color; the extremities were icy cold; even respiration was almost *nil*, and it required constant demands upon the patient to keep up the needed respiratory function, which, like that of the heart, was overwhelmed by the depressant effect of the chloride of barium. While awaiting the much-needed stimulants for which I had sent, even brandy not being available in this temperance stronghold, I thought each minute the smouldering vital spark would die out altogether. The intense abdominal pain complained of necessitated quick relief, and gr. $\frac{1}{8}$ of morphine, with gr. $\frac{1}{150}$ of atropine, was given hypodermatically, a larger dose under the circumstances not seeming justifiable. Previously to my arrival the patient had been vomiting and purging; after my coming, she was, at short intervals, seized with violent retching, there being no longer anything in the stomach; these efforts were followed by prolonged fainting attacks, from each of which I feared she would not rally. Treatment for shock was in the meanwhile being carried out to the fullest extent possible. External heat, frictions, ammonia inhalations were persisted in until the whiskey and carbonate of ammonia were obtained, when hypodermatics of the former were given at frequent intervals, the latter being administered by the mouth in five-grain doses every hour. For fully four hours I worked unceasingly on this plan, until the alarming condition began to yield and a little more regular heart-action was obtained. The respiratory function still needed considerable stimulation, and I finally left the house, giving strict injunctions not to let the patient sleep until I should have made my visit that morning, since, from the very beginning of the toxic symptoms, there had been almost uncontrollable drowsiness; and, if the patient were permitted to desist from voluntary respiratory effort, respiration would cease altogether, and stupor supervene, to overcome which would require unusual effort. I noted, also, that when the breathing was kept up, the heart's action would show a tendency to improvement; but with cessation of the respiratory act the radial pulse would fade entirely, the heaving action of the heart being for the time the only evidence of vital function.

At my next visit the condition of the patient was much improved, and, beyond a tendency to faintness when the head was elevated, there was little to recall the terrible experience of the previous night. I then obtained the following account of the events of the preceding day. The patient had taken two doses of the barium salt with no unpleasant result, stating that the medicine produced a feeling of drowsiness, so that for the first time in weeks she was able to obtain refreshing sleep during the afternoon. About six o'clock she took a teaspoonful of pulvis glycyrrhizæ compositus to overcome a constipation of several days' duration. The first unpleasant effects then showed themselves; she began to be sick at the stomach; there was profuse purgation, accompanied by severe pain of a burning character. At eight o'clock she took the third dose of barium chloride; an hour later the symptoms were so distressing that she called for assistance, the family having retired early that night. Even then the nature of the trouble was not suspected either by the patient herself or by her family; she attributed the disturbance to the effects of the laxative powder, which had at times acted somewhat similarly, and it was only when the vomiting and purging began to be uncontrollable and were followed by attacks of fainting that the family became sufficiently alarmed to send for medical aid.

Convalescence was undisturbed by anything unpleasant. The patient was confined to bed for one week. The diet was milk; the carbonate of ammonia and brandy were continued for several days, until the tendency to faintness already mentioned was overcome. The heart's action, which had been reduced during the attack to an extremely low rate, steadily improved, and, while the patient kept in bed, was full and regular, and did not exceed 84 beats per minute. After she was out of bed this was somewhat increased to about 100 per minute, but the pulse preserved its fulness and regularity. As soon as she resumed her household duties, I put her on the barium preparation in doses of a half fluid-drachm of a one per cent. solution, increasing the dose gradually until she is now taking two fluid-drachms of the solution, or nearly the same dose as that with which I began the administration, but with far more comfort to both patient and physician. She visited me recently at my office, and was in excellent condition of health, saying that she "never felt better in her life." She eats and sleeps well, suffers no pain about the heart, and attacks of palpitation have only occurred when she has omitted taking her medicine as directed.

In connection with this case I have made the following observations:

1. Barium chloride is a powerful irritant poison, of somewhat unreliable character when used medicinally. While I have administered it in two-grain doses without result, and, as in the case cited, it has been given in as large a dose as five grains, t. i. d., without causing any irritating effect, in the present instance the administration of less than two grains, three times daily, was productive of nearly fatal poisoning.

2. While barium chloride undoubtedly exercises a highly beneficial action in certain cases of cardiac derangement that may not yield to either digitalis

or strophanthus, it must be remembered that it is powerfully depressant to the heart; its administration should, therefore, be begun with the smallest dose consistent with the demands of the case, half a fluidrachm of a one per cent. solution being advisable as the initial dose, to be increased as required.

3. In toxic doses, barium chloride would seem to be not only a corrosive poison and a depressant to the action of the heart, but threatening to life by its effect upon respiration as well. In the present case the similarity of the respiratory phenomena noted to those presented in opium narcosis will have been remarked. Two possible occurrences must, therefore, be eliminated, viz.: Was there opium-poisoning present, either as a result of self-administration of the drug, or as a result of the hypodermatic use of gr. ⅛ of morphine sulphate that I gave the patient soon after my arrival? The first possibility, either as an accidental occurrence or otherwise, is negatived by the testimony of the patient herself to that effect. On the second point, I think that not only is the history of the case sufficiently convincing to the contrary, but very few would maintain that such overwhelming effects of the drug could result from so small a dose of morphine, even when given under the conditions that existed. While I gave it with some misgivings, owing to the desperate condition of the patient, her intense suffering necessitated its administration; as it proved almost immediately beneficial, not only in allaying the violent pain but also in quieting the distressing retching, which demanded quick relief, I could but consider it entirely justifiable. The following considerations, however, fully warrant the belief that opium-narcosis was *not* present as a factor in the history of this case:

(*a*) The absence of the "pin-hole" condition of the pupils, which should have been present were toxic effects of morphine produced. The pupils were only moderately contracted, and sensible to the light test.

(*b*) The same condition of respiratory failure was present *prior to* the administration of the morphine as was noted *subsequently* to its use.

Has, then, the chloride of barium a direct depressant action upon the respiration, or was the condition noted due to the secondary effects of the barium salt—the cerebral congestion dependent on cardiac failure?

4. In the employment of chloride of barium, the possible influence of purgative medicine should be borne in mind. Whether or not the drachm dose of the licorice powder had any effect in the production of the unpleasant conditions described in the present paper, I do not pretend to say; but, as barium chloride is irritating to the mucous membrane, the conjoined administration of purgatives should at least be followed by careful observation. I have recently used barium chloride in another case of heart disease, in which both mitral and tricuspid valves are chronically diseased, employing the minimum dose, but was obliged to discontinue its use on account of its irritating effect upon the bowels.

A KNIFE-BLADE FOUND IN THE BRAIN YEARS AFTER ITS ENTRANCE, DEATH RESULTING FROM OTHER CAUSES.

BY RICHARD SLEE, M.D.,
ASSISTANT TO THE DEPARTMENT OF PHYSIOLOGY, HOAGLAND LABORATORY, BROOKLYN, N. Y.

THE unexpected finding of a knife-blade, firmly imbedded in the skull, and penetrating the brain to the depth of one inch, would seem of sufficiently rare occurrence to warrant the reporting of the case. The interest is heightened by the fact that the knife-blade had been where it was found for a number of years, without giving rise to the slightest symptom.

C. Capsule turned back from knife-blade. D. Adherent dura.

On the evening of February 12, 1890, a man was brought into the City Hospital, Brooklyn, by the ambulance surgeon, suffering from several bullet-wounds. One ball was lodged in the left thigh, another had passed through the same thigh at about its middle, while the third and fatal ball entered the abdomen on a line with the umbilicus, and about two inches to the left of it. When admitted, the man was suffering from profound shock, but, improving during the night, he was operated on in the morning, and the intestines, perforated in a number of places, were sutured. The wound was placed in the best possible condition, but, with all the precautions taken, the man died of general septic peritonitis on the evening of the 14th.

As it was a coroner's case, an autopsy was held the next day at 2 P.M. On removing the brain, I felt a

sharp projecting point in the posterior fossa, on the left side. At first, I thought that this was one of the so-called ivory exostoses, but, on dissecting the scalp away from the outer surface of the skull, I found a foreign body of some kind that had penetrated the skull. A close examination of the scalp was now made without finding evidence of any wound, recent or old. The section of skull shown in the cut was then removed, and I found part of a knife-blade, $\frac{5}{16}$ of an inch in width, projecting into the brain to the depth of one inch. It had entered the skull about $3\frac{3}{4}$ inches posteriorly to the left external auditory meatus, in the line of the occipito-parietal suture, penetrating the lower posterior portion of the occipital lobe. The point of the blade was ensheathed in a strong fibrous capsule, about half an inch thick, that was adherent to the brain and its membranes by old and firm adhesions. The brain in the neighborhood was apparently normal, save a very slight thickening of its membranes in the immediate vicinity of the knife-blade. The blade was black and corroded, and everything pointed to the fact that it had been in its position for a number of years. There was no depression or displacement of the bone, and the blade had evidently passed between the sutures, probably in boyhood, when the bones were softer, and the sutures not as firmly interlocked as in the specimen when removed. The knife-blade had been broken just on a level with the external surface of the skull, and the man never knew the extent of the injury, as he enjoyed the best of health up to the time he was shot.

After the autopsy I set about trying to learn just how long before his death the injury had occurred. From his wife and mother I learned that, to the best of their knowledge, he had never received any injury of a serious nature. He had always enjoyed good health, never having had even a headache, had always been in good spirits, and was considered an able-bodied workman at his trade, that of a plumber.

There are a few authentic cases on record of persons living for a longer or shorter time with foreign bodies in their brains. In the larger percentage of cases the foreign bodies were bullets, and in most of the reported cases these, sooner or later, caused the death of the victim. O. Callaghan reports the case of an officer who lived seven years with the breech of a gun, weighing three ounces, lodged in his brain (Erichsen's *Surgery*, vol. i. p. 728).

In the *Annual of the Universal Medical Sciences*, 1888 (vol. ii. pp. 299–301), in addition to a number of cases of bullet-wounds, there are reported two cases somewhat similar to that of mine. One case was reported by Dr. Wilson, in which a copper paper-file penetrated the right side of the occipital bone, near its junction with the petrous portion of the temporal bone, and passed for more than three inches into the brain; profound collapse, with stertorous breathing, followed, but the subsequent recovery was complete. H. C. Dalton reports a case of punctured wound of the brain, in which a knife-blade entered the temple three-quarters of an inch behind the external canthus of the right eye, and penetrated fully two inches. There seems to be no doubt that the knife-blade penetrated the brain. No explorations were made; antiseptic dressings and ice-bags were applied to the head, and purgatives and morphine were given. The recovery was slow, but was considered complete.

The instruments used in the cases reported probably did no more damage to the brain-substance than would the exploring-needle that many surgeons use. Moreover, the fact that the foreign bodies did not remain in the brain very materially lessened the gravity of the case. In my case we have the following prominent facts that make it of more than usual interest: 1. The wound was so slight as to escape notice when inflicted, and, from all I could learn, received no treatment, not even rest; 2. It gave rise to no symptoms whatever during the life of the patient; 3. The man was about thirty years old, and, in all probability, the blade had been in the location in which it was found for a number of years.

I think this case argues in favor of the treatment recommended by some authorities for penetrating wounds of the brain, *i. e.*, immediate cleansing of the wound and placing it in an aseptic condition—closing the wound without attempting to explore or remove the foreign body. In the war of Tonkin and Formosa this treatment was followed by a mortality of only 10 per cent. as contrasted with 60 per cent. in the war of the American Rebellion, in which all wounds were explored and attempts made to remove the foreign body.

The specimen from which the drawing was made is now in the museum of the Hoagland Laboratory, Brooklyn, N. Y.

ORIGINAL LECTURE.

THE HEART: ITS MURMURS, THEIR DIAGNOSIS AND TREATMENT, AND THE ACTION OF THE CARDIAC TONICS AS A CLASS.[1]

By WILLIAM HENRY PORTER, M.D.,
PROFESSOR OF CLINICAL MEDICINE AND PATHOLOGY IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

LECTURE III.

Gentlemen: In the two preceding lectures we have carefully studied the various ways in which valvular lesions and cardiac murmurs are produced; also the methods at our command for accurately diagnosticating these conditions.

When we go over the chest of every patient in a regu-

[1] A series of lectures delivered at the New York Post-Graduate Medical School and Hospital.

lar and systematic manner—studying first the mitral indirect and direct areas, then the aortic indirect and direct, and determining as to the presence or absence of abnormal sounds, and the direction of transmission when present, in accordance with the rules already laid down—we are able to determine with positive accuracy whether murmurs are present or not.

From the result of this examination, plus the clinical history of the case, we are able to determine the character of the lesion or lesions in consequence of which the abnormal sound or sounds are produced.

By this method we can distinguish four murmurs almost as easily as we can detect a single and isolated sound. In fact, we are simply dealing with a single murmur at a time, although the final result of our observations may be the detection of double murmurs, both at the mitral and aortic orifices.

Having acquired this degree of skill in diagnosis, and with it having learned to recognize the exact pathological lesion present, we are placed in a much better position to consider the physiological and therapeutic action of the drugs that may be used to assist nature in compensating for the pathological and mechanical deficiencies of the heart, and thereby maintain the physiological and nutritive conditions of the system at large.

At this point, however, it must be assumed that nature has already subdued or removed from the system the infectious element that caused the endarterial or endocardial irritation, and that we have to deal with the cardiac murmur and the established lesion purely as a mechanical defect, which is to a degree stationary in character. Granting this, we can understandingly discuss the comparative merits of that class of remedies commonly regarded as cardiants.

It can further be asserted that, by augmenting the nutritive activity of the heart and increasing its working capacity to a degree related to the simple mechanical defect, the individual will be placed in a thoroughly good condition—in other words, in a normal state, so far as the action of the heart from a mechanical point of view is concerned. Physiologically, of course, there is always a certain degree of compensatory hypertrophy and some over-distention of one or more of the cavities of the heart, as well as a localized vascular engorgement at some point of the circulatory apparatus. This increased compensatory action of the heart prevents any material embarrassment in the workings of the physiological economy. If, however, at any time such an individual should be seized with an infectious disease, his nutrition, from any cause, becoming impaired, the vitality of the cardiac muscle will be rapidly reduced and the compensatory condition deranged to such a degree that the mechanical action of the heart will be seriously interfered with. Under such circumstances the prognosis is much graver than it would be in the absence of a cardiac lesion, even though the acute or infectious disease *per se* be comparatively mild in character.

Before proceeding further, it is necessary to formulate a standard by which the terms commonly employed, such as cardiac sedatives, depressants, stimulants and tonics are to be applied. By limiting the use of these terms much confusion can be avoided. By keeping strictly within sharply defined limitations there can be no question as to the exact action and the result to be obtained from the administration of one or more of these drugs.

1. *A cardiac sedative* is best defined as a drug or remedy that tends to stimulate a depressed, or quiet an irritable nervous system, so that it will assume a more perfect and uniform action, and in this way ultimately increase, as it were, the general innervating and inhibitory power of the entire nervous mechanism, thereby inducing a more even and harmonious performance of all the bodily functions. When this result has been accomplished, a heart, previously acting in a tumultuous and irregular manner, will be found to have resumed a normal and rhythmical action; whatever distressing symptoms may have been present as the result of the abnormal movements of the heart, will have been quickly dissipated.

The salts of bromine are probably the best examples of this kind of drug. They are often found to be of great service in regulating the tumultuous action of the heart in hyperæsthetic subjects. They are, however, of no avail when a truly mechanical defect, either functional or organic, has been developed.

2. *A cardiac depressant* is best defined as a drug that will at once and perceptibly depress both the force and the frequency of the action of the heart. This result is brought about by a direct influence upon the heart-muscle or secondarily through the nervous system.

This class is best represented by aconite, veratrum viride, and the vegetable acids. All the nitrates, nitrites, and potassium salts may be placed in this group, together with nitro-glycerin, amyl nitrite, etc. The last two and the potassium salts may be of great service in regulating a tumultuous and laboring heart in that class of cases in which an abnormally high tension in the arteries is causing an undue amount of resistance to the onward flow of the blood. In so much as the abnormally high tension is a causative factor in embarrassing the action of the heart, its diminution will seem to have stimulated and regulated the rhythm of the heart, although no direct or intrinsic action has been produced upon the heart or the nerve-centres that directly govern its movements.

3. *A cardiac stimulant* is best defined as a drug or remedy that calls into action the intrinsic or stored-up motor power of the cardiac muscle, but without directly affecting its nutritive condition. This result is brought about either by a direct influence upon the muscle-fibres through the intrinsic cardiac ganglia or by an extrinsic action originating in the cardiac centre of the medulla and transmitted through the centrifugal nerves to the heart-muscle.

The most typical example of this kind of stimulating action upon the heart is illustrated by the application of a high degree of dry heat to the integument directly over the præcordial area. By this application, without supplying any new substance to the system, the cardiac muscle is made to do more work simply by a reflex action transmitted to the heart through its nervous mechanism, the inherent vital or stored-up motor power of the cardiac muscle is called into more vigorous and effective action. So far as the work accomplished is concerned, this is equivalent to stimulation.

Owing, however, to the fact that neither the nutritive

condition of the system at large nor that of the heart in particular is augmented, this increased action of the heart, if continued, will soon result in deterioration of the cardiac muscle, equivalent to a poisonous action upon the muscle-fibres. In this instance the damage is brought about in a simple manner, as the result of increased muscular work without an equivalent increase in the nutritive supply.

The majority of drugs that belong to this class, excepting alcohol, are glucosides. As a rule, the cardiac stimulants are compounds of CHO that cannot be oxidized within the system to form nitrogenous elements; consequently they are non-nutritious. They are rapidly converted into carbon dioxide and water, during the process of which energy and heat are evolved, and, as it were, a reflex irritation is brought to bear upon the nervous system and heart. In this manner the working power of the cardiac muscle is temporarily augmented, but at the same time its nutrition is diminished; as a result, brought about either directly or indirectly, the muscle-tissue is poisoned, so that ultimately its vitality is greatly reduced, if not absolutely destroyed.

A few of the drugs in this group are toxic alkaloids, containing nitrogen. While theoretically capable, in the cycle of changes in the body, of being oxidized into the final products, urea, carbon dioxide and water, they are, nevertheless, poisonous, like many other proteid bodies, such as the toxic ptomaïnes and leucomaïnes. In passing through the system, these substances appear to have the property of temporarily exciting the heart-muscle to more vigorous action, but the result is transient and is rapidly followed by a decidedly poisonous action upon the muscle tissue proper.

4. *A cardiac tonic* is best defined as a drug or remedy that acts upon the heart intrinsically or extrinsically (usually in the latter way), or by a combination of the two; its ultimate result is the development of a higher degree of muscle power by the formation of an increased volume of muscle protoplasm, and not alone by simply calling into action stored motor power at the expense of the vitality of the muscular elements.

This class of remedies is represented by the drugs containing CHNO, such as caffeine, morphine, strychnine and atropine, and by the food-stuffs containing CHNOS, all of which are capable of being changed or oxidized within the system. In passing through the economy, these nitrogenous bodies aid in forming body-tissue, and are finally converted into the ultimate products of tissue-waste and excreted as urea, carbon dioxide and water. Cardiac tonics must first pass through a cycle of changes in the body that result in the formation of all sorts of proteid compounds, or, at least, these medicinal agents most positively retard the retrograde metamorphosis, despite the increased work. At this point it may be well to state that, although the atomic composition of these drugs will not warrant the supposition that in the small quantities in which they are used they are equal in tissue-forming power to the proteid substances taken as food, there is much clinical evidence of a positive kind which seems to prove that, while they do not constitute the most perfect food-stuffs and tissue-forming elements in passing through the cycle of change from their introduction to their excretion as urea, carbon dioxide and water, they do have a most wonderful power in developing and maintaining the nutritive vitality of the proteid elements of the various body-tissues and organs. To more completely illustrate this subject, the accompanying table has been prepared. This shows at a glance the active principles of the different drugs, their chemical composition, and their comparative actions and merits most clearly.

In defining the different classes of drugs, sufficient has already been said to indicate where the sedative and depressant cardiants can be used to advantage in the treatment of affections of the heart; consequently the drugs of those two groups will not be individually considered. We will pass directly to the study of the stimulants and tonics.

In the class of stimulants containing CHO, alcohol unquestionably stands first. The action of alcohol upon the heart can be summarized as follows: As a result of its oxidization within the system into its final excretory products, carbon dioxide and water, energy is rapidly evolved, by which the heart is influenced, either directly or reflexly through its nervous mechanism, in such a manner that the inherent working-power of the cardiac muscle is greatly augmented. Owing, however, to the chemical fact that the CHO elements that form the alcoholic compound are not capable of transformation by the physiological economy into nitrogenous substances, neither the body at large, nor the heart-muscle in particular, can, by the intrinsic influence of this agent, be directly improved in their nutritive functions. But as a result of the development of this new energy by the rapid oxidization of the alcohol, the nervous mechanism of the body is influenced in such a way that the action of the heart becomes stronger and the arterioles in general moderately dilated, so that a larger volume of blood is driven more slowly through the capillary system. If at the same time a sufficient quantity of proteid material is introduced into the nutritive channels, the modification in the movements of the heart, together with the moderately dilated condition of the arterioles, necessarily causes a larger volume of more highly nutritive blood to flow through the arterial capillaries in a given space of time; consequently the general nutrition and that of the heart-muscle as well is greatly improved. By this indirect and secondary influence alcohol may be looked upon as both a stimulant and a tonic to the heart. The latter term, however, is not justly attributable to the action of the alcohol alone, for the evident reason that when a patient is restricted to an alcoholic diet, or takes alcohol in large quantities, or to the extent that the digestion and assimilation of proteids is impeded, or the oxygenating capacity is overtaxed, a positively deteriorated condition of the system is at once induced.

To completely understand the increase and decrease of nutrition, either local or general, a clear conception of the methods by which Nature governs this physiological problem is absolutely essential. Briefly stated, it is as follows: that all nutritive interchange between the blood and perivascular tissue is effected through the *arterial capillaries;* that when the blood has passed this point and entered the intermediate and venous capillaries, all the nutritive interchange is practically at an end; that normally a given volume of blood, having a certain quality when passing at a definite rate of speed through the arterial capillaries with a given tension, will allow

CARDIAC STIMULANTS.

Drug.	Active principle.	Its form and formulæ.	Solubility in Water.	Solubility in Alcohol.	Action on the rapidity and muscular power of the heart.	Action upon the small bloodvessels, arterioles and capillaries.	Action as a diuretic.
Alcohol . . .	Alcohol.	C_2H_6O	.....	.....	Increases the working capacity; slows a rapid, increases a slow heart; muscle secondarily exhausted.	Slightly contracts the general arterioles; dilates splenic arcade; nutritive tone improved.	Slightly diuretic.
Digitalis . . .	Digitoxin.	$C_{21}H_{32}O_7$	Insoluble.	Sparingly.	Shortens systole; lengthens diastole; slows action of heart; increases muscle power, then poisons the muscle.	Vessels highly contracted in general; dilates splenic arcade; nutritive tone diminished.	With venous congestion, are good diuretics.
	Digitalin.	Glucoside $C_5H_8O_2$	Nearly insoluble.	Readily.	Shortens systole; lengthens diastole; slows action of heart; increases muscle power, then poisons the muscle.	Vessels highly contracted in general; dilates splenic arcade; nutritive tone diminished.	
	Digitalein.	Glucoside $C_{25}H_{40}O_{25}$	Freely soluble	Readily.	Shortens systole; lengthens diastole; slows action of heart; increases muscle power, then poisons the muscle.	Vessels highly contracted in general; dilates splenic arcade; nutritive tone diminished.	
	Digitonin.	Glucoside $C_{31}H_{52}O_{17}$	Readily soluble.	Sparingly.	Lengthens systole; shortens diastole; antagonizes digitoxin, digitalin, and digitalein, and poisons the muscle.	General arterial system and splenic arcade dilated; nutritive tone diminished.	Not diuretic.
	Digitin.	Glucoside . . .	.....	.....	No special action known.	No special action.	No action.
Convallaria . .	Convallamarin.	Glucoside $C_{23}H_{44}O_{11}$	Soluble.	Soluble.	Increases the length and force of the systole; slows action of heart, and poisons the muscle.	Arterioles dilated; increase of tension is due to increased heart-power.	Evidence contradictory.
	Convallarin.	Glucoside $C_{34}H_{62}O_{11}$	Insoluble.	Soluble.	No action on the heart, is somewhat purgative in action.	Not used to act on vessels; if it exerts action, it lowers tension.	No use.
Strophanthus .	Strophanthin.	Crystalline glucoside $C_{24}H_{34}O_{10}$	Soluble.	Soluble.	Lenthens systole; shortens diastole; slows action of heart; increases muscle power, then poisons the muscle.	Tension primarily unaffected; may be raised by increased heart-power.	May be diuretic by improving the heart, but not primarily.
	Strophanthadin	Glucoside . . .	Insoluble.	Insoluble.	Inert so far as known.	Tension primarily unaffected; may be raised by increased heart-power.	
	Ineine. (?)	Alkaloid	....	.....	Action given the same as that for strophanthin.	Tension primarily unaffected; may be raised by increased heart-power.	
	Strophantine(?)	Toxic alkaloid . .	Soluble.	Soluble.	Action given the same as that for strophanthin, but more poisonous to the muscle protoplasm.	Probably lowers tension; evidence uncertain.	Not diuretic.
Scoparius or Broom . .	Scoparin.	Neutral body $C_{21}H_{22}O_{10}$	Soluble.	.....	Exact action uncertain; possibly diuretic in nature.	.....	Not clearly stated.
	Sparteine.	Liquid alkaloid $C_{15}H_{26}N_2$	Insoluble.	Soluble.	Slows action; lengthens and increases force of the systole; shortens diastole; poisons the muscle tissue.	Contracts arterioles in general and in splenic arcade; nutritive tone diminished.	Not diuretic.
Adonis vernalis	Adonidin.	Glucoside . . .	Soluble.	.....	Action almost identical with that of digitoxin, but ten times more poisonous to muscle tissue.	Slight contraction of systemic arterioles; those in splenic arcade dilated.	Slightly diuretic.

CARDIAC TONICS.

Drug.	Active principle.	Its form and formulæ.	Solubility in Water.	Solubility in Alcohol.	Action on the rapidity and muscular power of the heart.	Action upon the small bloodvessels, arterioles and capillaries.	Action as a diuretic.
Ammonium . .	Ammonia.	Carbonate $N_3H_{11}C_2O_5$	Soluble.	Soluble.	Increases working capacity; slows a rapid and increases a slow heart; muscle not poisoned.	Slightly contracts arterioles in general and tends to produce normal tone.	Slightly diuretic.
Caffea	Caffeine.	Alkaloid $C_8H_{10}N_4O_2H_2O$	Sparingly soluble.	Sparingly.	Increases the force and frequency of muscular contraction; lengthens systole; muscle tissue nourished.	Contracts arterioles in general, but dilates those in splenic arcade; nutritive tone improved.	Markedly diuretic.
Nux vomica . .	Strychnine.	Alkaloid $C_{21}H_{22}N_2O_2$	Soluble.	Soluble.	Increases the force and frequency of the muscular contraction; systole lengthened; muscle unpoisoned.	Slightly contracts arterioles in general, but dilates splenic arcade; nutritive tone improved.	Slightly diuretic.
	Brucine.	Alkaloid $C_{23}H_{26}N_2O_4$	.....	.....	Same as of strychnine, but weaker in power.		
Belladonna . .	Atropine.	Alkaloid $C_{17}H_{23}NO_3$	Soluble.	Soluble.	Increases the force and frequency of the muscular contraction; muscle unpoisoned.	Marked contraction, including splenic arcade; nutritive tone decreased.	Not diuretic.
Opium	Morphine and sixteen other alkaloids.	Alkaloid $C_{17}H_{19}NO_3H_2O$	Soluble.	Soluble.	Slows a rapid and increases a slow heart; muscle power increased; systole lengthened; diastole prolonged, and muscular tissue nourished.	When vessels dilated causes contraction; when vessel contracted, causes dilation; general regulator.	Slightly diuretic.

of an interchange between the blood and tissue which is equivalent to the work accomplished, thus exactly repairing the loss resulting from the tissue or glandular work performed.

An unduly high or low arterial tension will so change the speed of the blood in these nutritive capillaries, that even should the quality of the blood remain the same the nutrition will fall below the normal standard. The high tension is the more dangerous of the two, for when general the blood passes so rapidly beyond the nutritive point that the system as a whole is, as it were, starved to death. This assertion is most beautifully illustrated by those cases reported of speedy death induced by the continued high tension that followed the uninterrupted administration of powdered digitalis;[1] also in the condition known as shock, in which the great bulk of the blood suddenly passes to the venous side of the circulation—this being now recognized as the chief pathological factor to be overcome in the treatment of that condition.

When the arterial tension is abnormally low, the disturbance in the nutritive function is not so quickly noted, and for a time it is even increased, but in both instances it is ultimately impaired until, finally, the glandular activity of the body is diminished and the nutritive quality of the blood very decidedly reduced. A thorough understanding of this physiological law helps to clearly explain many actions that follow the introduction of medicinal agents into the system. By taking advantage of this law and lowering or raising the tension, the nutritive processes can often be modified or changed to such a degree that pathological conditions can be dissipated and the part restored to its original standard; or, on the other hand, a normal condition may be converted into a pathological one. When in a perfect physiological condition, the system is continually making this vascular alteration to meet the constant changes in the nutritive quality of the blood and the varying amount of work that is to be performed by the different body-tissues and glands.

Both the high and low tension in the arteries are due to a similar cause, but differing in the degree of its intensity of action. In both the causative influence leads to nervous exhaustion. When the tension is heightened a hyperæsthetic condition of the nervous centres which govern the vaso-constrictors is produced, and, as a result, both normal and pathological influences tend to excite an undue volume of energy and an increased and often irregular innervating impulse is distributed through the vaso-constrictor nerves, thus inducing and maintaining the abnormally high tension. When the tension is lowered the nervous exhaustion is more complete. The normal or pathological irritation is not sufficient to stimulate the vasomotor centre and excite the vaso-innervatory impulses to the arterial wall, and from the loss of this action the contained blood distends the vessels and gives the erroneous impression of the existence of vaso-dilator nerves and influences. At times this exhaustion becomes so great that even the most powerful drugs at our command will not excite innervating impulses, and the patient, of necessity, dies.

In proportion to the quantity taken, alcohol, up to a certain point, has the property of meeting both these conditions, so that in the one case it will lower the tension and improve the heart's action, and in the other it will raise the tension and increase the working capacity of the cardiac muscle. In fact, in all cases in which the use of alcohol is kept strictly within the physiological limit its tendency is to bring the heart's action and the vascular tension to the normal standard or a little above. When alcohol is used within these sharply defined bounds, together with a well-regulated and purely nutritive diet, in the sense of tissue-formation, it is without doubt or question one of the most powerful therapeutic agents for good at the command of the physician. But if the alcohol is used continuously, and especially in excess, yielding as it does only heat and energy while it is rapidly being oxidized into carbon dioxide and water, it has a pronounced tendency to exhaust the oxygenating capacity of the system, and thus prevents a perfect transformation of the proteids, until finally all the functions of the body are decidedly changed, if not completely destroyed. This is most apparent in the nervous system, as evinced by the impaired mental faculty. Alcohol is, therefore, a drug that produces true starvation, and whenever used in excess, either for a short or long period of time, must of necessity alter the nutritive quality of the blood, change the action of the heart and the vascular tension, and ultimately become a potent factor in producing permanent pathological lesions. The quantity of alcohol taken and the degree of disturbance of proteid oxidization, and especially the latter, are the factors that will determine the rapidity with which these abnormal conditions are developed.

The well-known and often-demonstrated rapidity with which all the bodily functions are restored so soon as the excess of alcohol is withheld from the system and in its place the proteids administered and perfectly oxidized, shows quite conclusively that alcohol *per se* has no poisonous effect upon the body, but that it acts as all CHO compounds must when taken in excess. They are all quickly and easily oxidized, thus using up the oxygen taken in by the inspiratory act, leaving an insufficient quantity to accomplish the more difficult and complex act known as proteid oxidization. This naturally results in an incomplete metabolism of these elements and the development of an almost innumerable variety of abnormal and in many instances decidedly poisonous substances. The long list of poisonous ptomaïnes, leucomaïnes and toxines already discovered fully corroborates this assumption. These compounds are not developed out of the CHO substances, but originate directly from the CHNOS elements which have been imperfectly transformed. The varied action of this large number of abnormal and poisonous nitrogenous compounds upon the nervous system and functions of the body in a large measure affords not only a clear but rational explanation of the damaging effects upon the mental faculties which are so often, but erroneously, credited to the direct action of the alcohol. The nervous system, when over-stimulated by this large amount of heat and energy evolved by this sudden oxidization of alcohol, and having for its nutriment these toxic nitrogenous compounds instead of those perfectly formed, cannot work normally, but is of necessity compelled to act in the abnormal manner indicated. The variety of toxic compounds developed also explains the great number of abnormal manifesta-

[1] Oberstabsartzt, Deutsche militärärtztliche Zeitschrift, 1876.

tions that are from time to time developed in different cases and even in the same individual at different times. These facts are applicable to both the acute and chronic cases that have resulted from over-indulgence in alcohol.

Considered from a purely chemico-physiological standpoint, the damaging effects of alcohol upon the system are little if any greater than those that follow the administration of an equal quantity or an over-indulgence in any of the other CHO group of compounds. But owing to the almost instantaneous absorption and the lightning-like transformation of the alcohol into other chemical compounds within the system, its effects are more quickly and positively felt.

This influence, however, is almost as speedily dissipated, and leaves the nervous system in particular in an overworked and poorly nourished condition; in fact, so much exhausted that a growing demand for repeated and increased stimulation is induced to overcome this state of depression. This same condition is induced by all CHO compounds, but reaches its maximum degree in the case of alcohol.

The oxygenating capacity of the system is so speedily taxed by the introduction of alcohol that all the functions of the body are at first greatly augmented, then lowered and modified until finally they become decidedly subnormal. That the damaging effects upon the system which are found in conjunction with the free use of alcohol are not due to the direct influence of the alcohol *per se* upon the blood, tissues and glands, but is the result of the sudden tax upon the oxygenating capacity of the animal economy and the imperfect metabolism of the proteid elements, is certain. This is clearly proved by the elaborate experiments of Dr. Anstie, who found that after keeping a dog super-saturated with alcohol for days, and then introducing into the stomach a considerable quantity of alcohol just prior to killing the animal, the total quantity of alcohol that could be obtained from the dog by distillation of every particle of the animal's tissue, including the bones, hide and hair, was not more than one drachm, although several ounces had been injected into the stomach almost immediately before death. This kind of observation shows quite conclusively that alcohol as such is rapidly dissipated within the system; even when large quantities are taken into the stomach an infinitesimally small quantity is excreted from the body in its original form, C_2H_6O.

One such thorough quantitative experiment as this outweighs in value all the qualitative experiments that can be made with the most sensitive reagents that are capable of detecting minute quantities of alcohol.

Theories based upon the former experiments are sound and are in accord with clinical and pathological knowledge, while those based upon the latter become little less than gross fabrications.

The chief reasons why the cerebral disturbances and damaging effects are not so quickly developed after the introduction of all the other CHO compounds are, that they must first be digested in the alimentary tract and liver—as the grain is transformed in the malting and brewing house—and also that they are much more slowly absorbed by the entero-hepatic circulation in their course to the liver. Even there they are tardily converted into alcoholic compounds, yielding heat and energy, but slowly as compared with alcohol. While it may take twenty-four hours or longer to convert a given quantity of starch and sugar into alcohol and finally into its excretory product, carbon dioxide and water, a much larger quantity of alcohol may be so transformed in a much shorter length of time, possibly in a few minutes. Heat and energy are, however, evolved in both instances; starch, sugar and alcohol all yield the same excrementitious products, but without combining with the nitrogenous food-stuffs to form the proteid tissues of the system.

The starch, sugars and fats, as well as the alcohol, when taken in excess, have a marked tendency to disturb proteid-metabolism; the alcohol most rapidly, because when introduced it is always a stage further advanced in the transition and is capable of being directly oxidized. From this fact, that members of both groups can pervert proteid-oxidization in the same manner, we frequently see as the result of over-indulgence in any or all of the CHO compounds, exclusive of alcohol, disturbances that, when viewed from a purely chemico-physiological standpoint are found to be equally as damaging in their effects upon the system as those that follow the free and excessive use of alcohol. They do not, however, give rise to the striking condition known as intoxication, which makes a human being so revolting to his fellow-men, but they do produce insomnia, hypochondriasis, suicidal mania, and in fact all forms of insane delusions, symptomatic of changes that in their final results are often equally as damaging to the mental faculties and to life as those that follow alcoholic excesses.

When the quantity of alcohol administered is kept within the limits that do not interfere with the complete and perfect oxidization of the proteid compounds, the physiological functions of the body will not be impaired, but often very decidedly augmented. The alcohol, being rapidly oxidized within the system, with a comparatively small expenditure of oxygen, and at the same time yielding a proportionately large amount of heat and energy for the quantity of oxygen used, is found to be capable of maintaining body heat and energy with a small expenditure of vital force. This saving is effected in various ways; one is by sparing nature the necessity of first transforming starch and sugar into alcohol before they can be utilized by the animal economy.

When this process of forming alcohol-like elements has to be performed in the intestine, liver, and blood—instead of taking the alcohol from the malting and brewing house, it necessitates a large expenditure of glandular activity, energy, and the supply of a considerable quantity of oxygen on the part of the system, and even when accomplished the sum-total of heat and energy developed is small in comparison with the results obtained where alcohol is used.

In health, the development of this large amount of heat and energy with the comparatively small expenditure of oxygen and glandular activity is not so desirable and is apt to be carried to excess, but when a diseased process is developed and the system is suddenly overtaxed and its vital force lowered by the introduction of a foreign body, as a germ, ptomaïne, leucomaïne, or toxine, it becomes necessary to save oxygen and to harbor the vital resources in every way possible, the nutritive vitality may be maintained until the offending

element can be expelled. Under these circumstances, alcohol is of unparalleled service to the system, for by its action oxygen is saved, glandular activity conserved and the necessary expenditure of heat and energy to carry on the secretory and excretory work reduced to the minimum. In fact, there are times when the functions of digestion and absorption are at such a low ebb that nature is compelled to feed upon its own tissues or starve. If alcohol be administered at this time the body-heat and energy may be artificially maintained with a decided saving of oxygen and vital force. By this gain in oxygen, with stimulation of the nervous system, digestion, absorption, and assimilation are sustained, and a larger amount of a more perfect proteid-metabolism is accomplished; the nutrition of the body is improved, its vital energy raised, and its power to resist the inroads of infectious elements brought to the highest possible standard. It also enables nature to more quickly eliminate these poisons, thereby shortening the duration and diminishing the intensity of the pathological processes, thus often saving a life that without its use must be lost. It is by this same saving of oxygen, this increase in energy, this conservation of glandular activity and vital force that alcohol enables the system more perfectly to oxidize and assimilate the proteid elements of the food-stuffs; alcohol thus appears to sustain thoroughly or even increase the body-weight when the diet is insufficient. This favorable action, however, is only temporary in character and cannot be maintained indefinitely, but must be followed in due time by the requisite amount of nitrogenous food-stuffs or the bodily nutrition will ultimately fail.

In this light, alcohol becomes a valuable therapeutic agent in the management of many cardiac lesions, but in no sense can it be regarded as a food-stuff in itself. By improving the general nutritive condition in this secondary manner, and by regulating the heart's action and modifying the vascular tension, alcohol will often enable us to develop a compensatory hypertrophy of the heart-muscle more rapidly and more effectually than can be accomplished with any or all of the other therapeutic agents at our command.

In using alcohol it should always be borne in mind that it is rapidly oxidized, that it yields a large amount of energy, that it is a starvation compound and must have associated with it a liberal supply of nitrogenous compounds if the desired results are to be obtained. When alcohol is used, starch, sugar and fat should be omitted entirely or be taken in small quantities, otherwise nature will be deprived of the good effects that we are seeking to attain. We should also keep in mind the fact that where alcohol is used beyond the physiological limit it decidedly retards the oxidization of the proteid elements, lowers nutritive vitality, and the patient loses ground. When used in excess the effect is transitory; the functions of the body and especially those of the nervous system are exhausted instead of being strengthened, and depression is induced, with a constant craving for a similar kind of stimulation. Kept within these physiological limits, however, alcohol can never do harm but is a powerful aid to the system in disease and may often save valuable life when without it death must of necessity ensue.

The only sure guide to the use of alcohol in disease is found in the constitution of the urine and in its changes. When the digestion, assimilation and oxidization are perfectly effected, the normal standard will be maintained; but if disease attacks the system the reverse is the case. The relation between urea and uric acid is changed; the quantity of the former diminishes while the quantity of the latter increases. The alcohol should be administered until the urea rises and the uric acid falls to the normal standard. This accomplished, the heart's action and vascular tone will be placed in the best possible condition attainable from the use of alcohol.

CLINICAL MEMORANDA.

DEATH FROM ETHER.

BY MRS. CHARLOTTE B. BROWN, M.D.,
OF SAN FRANCISCO.

DEATH from ether is so rare that a record of each case seems of importance; hence the following report.

Mrs. H., a resident of Oakland, Cal., forty-one years of age; born in Indiana; had been married fifteen years, and had had two children, the youngest eight years of age; no miscarriages. Her mother is living and healthy at sixty-seven years; her father died of a fever at thirty years. Mrs. H. had never been a robust woman, and yet had never had any severe illness. About two years ago she began to suffer from uterine hemorrhage, and in the fall of 1889 consulted a gynecologist, who discovered and removed a small fibroid from the cervix. The operation was performed at her house, under ether, with prompt recovery.

In March, 1890, another fibroid, about an inch in diameter, was removed, also under ether, by the same physician, at his office. The parts were packed, and the patient was sent home in a carriage. On reaching home a violent hemorrhage occurred, and was with difficulty checked. She was blanched and never fully regained her former health and color. No mention of any other mass in the womb was made by the physician.

In January, 1891, and in March, profuse bleeding occurred. In March, Dr. C. Annette Buckel was called, and diagnosticated an intra-uterine fibroid, probably submucous. The hemorrhage was controlled and the patient liberally fed, and every means used to promote health and strength, with some success. But while the period in April was less profuse, in May it was more so, and her health began to fail. On June 1st she was sent to me for admission to the Hospital for Women and Children. The womb measured five and one-half inches and seemed to contain a single tumor. Examination showed heart, lungs and kidneys in as satisfactory a condition as was possible when general anæmia from loss of blood was so marked. I advised her not to delay entering the hospital. She did so, and was kept in bed during her menstrual period, when there was a moderate flow. Her appetite was good and her condition in no way unfavorable.

On June 10th a bundle of laminaria tents was introduced into the uterus and remained twenty hours. At 9.15 in the morning of the 11th, one teaspoonful of aromatic spirits of ammonia and one tablespoonful of whiskey were administered, and at 9.30 she was brought to the operating-

room. I listened to her heart as she was about to inhale the ether and heard nothing abnormal in the sounds. Her courage was good. Ether was given in a cone made of a towel, and she was very soon unconscious, the precise time not being noted. I irrigated the vagina, removed the tents, introduced a Barnes's dilator and distended it, followed by another of a larger size. I made a thorough examination of the mass, which was about three inches in diameter, attached by a broad base at the right posterior part of the fundus. I was working quite rapidly and was about to pass in the wire of the écraseur, when the assisting physicians said that her heart was beating poorly. A hypodermatic injection of tincture of digitalis and tincture of nux vomica, of each ten minims, was at once given. Her head slipped over the edge of the table, but no beat of the heart was felt. There were a few weak efforts at respiration for a moment or two, and then all was over. The faradic current was promptly applied and artificial respiration, by Sylvester's method, used. Hypodermatics of whiskey and ammonia were given repeatedly. These efforts were continued for an hour, but without avail. It was not more than five minutes from the first sign of collapse till she was dead, and not the slightest appearance of life was produced by all the means of resuscitation employed. I regret to be unable to record the quantity of ether used, but it was small, as she yielded to its action very promptly. It was less than a half-hour from her first inhalation before all was over.

The physicians present were Drs. Wanzer, Buckel, Smiley, LaFontaine, Nelson, Sherman and myself; all were most efficient in their labors in the case.

No post-mortem examination was made. The physician who was noting the pulse opened the patient's eyelid just after the first weak beat, and remarked that the pupils were widely dilated.

A CASE OF SKIN-GRAFTING FROM THE FROG.

BY GEORGE D. WESTON, M.D.,
OF FORT PAYNE, ALA.

IN a railroad wreck, George W., in addition to other injuries, was badly burned by steam. The parts burned extended from the nape of the neck to about four inches below the points of the scapulæ, and from the left shoulder-joint to the right, including at least two-thirds of the right upper arm, and especially the post-axillary fold. The inner third of the upper arm escaped. The burn was dressed with carbolized carron oil, the blisters having been cut just sufficiently to allow the serum to escape. On account of a dislocation of the clavicle, it was thought best for the patient to lie upon the back. The discharge was profuse and new blisters had to be opened each day. After a few weeks the skin and superficial fascia came off in large green sloughs; the discharge of pus was profuse and offensive, but the carbolized dressing soon stimulated the surface, so that healthy granulations sprang up and the whole surface was in good condition, but showed no tendency to the formation of skin. Some of the granulations were exuberant, and I had to cut them off with a knife and check their growth with nitrate of silver. The profuse discharge constantly weakened the patient and caused considerable elevation of temperature. I therefore had to use a great deal of stimulation. As something had to be done to induce the skin to form, I thought I would try skin-grafting, but the patient was so weak and had already so much surface granulating that he could not stand further denudation. I therefore thought I would try frog-skins. The white skin from the bellies of several frogs was removed, washed in clean water, cut into squares one-fourth or one-half inch across, and placed upon the granulated surface, the raw surface down. These were covered with oiled silk dipped in carbolized oil. The remainder of the back was dressed with benzoated oxide of zinc ointment. This was left for two or three days, the dressings, except the oiled silk, being changed at short intervals. When exposed, it was found that the grafts had a healthy, pink, transparent appearance, and the dressing was renewed as before. At the next dressing the grafts themselves could barely be distinguished, but, at the points where they were put on and for an inch or more around each, there was a pale bluish-white network that led me to infer that the grafts had been the means of inducing skin to form, but not in the same way I had seen in other skin-grafts—by forming a central island and spreading to meet that coming from the edges. From this time on, the patient continued to improve. The accident occurred March 22, 1890, and August 9th all had healed but a spot about the size of a silver dollar. At this time it was thought that a change of climate, by a visit to his old home near Boston, would complete the cure; so he was sent North on August 9th. He came back September 30th, with his back in a bad condition. Before going North, and during his stay there, large water-blisters would form, and these would have to heal like ordinary blisters. These proved very aggravating, both to physician and patient. As on his return I was away he was attended by my friend, Dr. Fowlkes, who used the benzoated oxide of zinc ointment that I had applied, and with fine success, so that when I returned, October 22d, the patient was nearly well again. From this time on, I dressed his back quite often, to look after the new blisters, and also to get the benefit of massage in causing the absorption of the excessive connective tissue that had been formed in the process of healing. This was especially marked on the right post-axillary fold. But by massage and use I think no operation will be necessary to obtain a fine and useful arm. There is at a few points a slight tendency to keloid-formation; otherwise the patient is perfectly strong and healthy. The scar has a thin tissue-paper appearance in most places, and as yet there is but little contraction.

A PRACTICABLE AND PAINLESS METHOD OF USING IODINE HYPODERMATICALLY.

BY A. O. SQUIER, M.D.,
OF SPRINGFIELD, MASS

IN THE MEDICAL NEWS of April 14, 1891, Dr. E. Fletcher Ingals, discussing the Shurly-Gibbes treatment of pulmonary tuberculosis, says: "It is usually best, excepting in advanced cases, to begin with iodine, though it is apt to cause considerable smarting," etc. In the *Therapeutic Gazette* for April, 1891, Drs. Shurly and Gibbes say: "The iodine solution gives considerable pain to some people, to others very little; but the gold solution gives little or none. We hope that a

solution can be made with lanolin, or something of that sort, which will obviate this objection in the case of iodine."

Having found the use of the iodine solution exceedingly painful, in one case so severe as to lead to the conclusion that if its use was persisted in, local anæsthesia, by means of spray or other more or less inconvenient method, must be resorted to, I found that the injection could be rendered absolutely painless by incorporating with the mixture as used by Drs. Shurly and Gibbes, a small quantity of creasote, or better, guaiacol. Another objection to the solution as prepared by Drs. Shurly and Gibbes is the large *quantity* necessary to be injected when it is desired to administer the full dose of one-half grain of iodine. This requires that sixty minims be introduced beneath the skin, and since the hypodermatic syringe, as usually made, has a capacity of but thirty minims, either the barrel must be unscrewed and refilled, the needle meanwhile being left sticking in the skin, or if the needle is withdrawn a second puncture must be made, all requiring time and causing additional pain. This might be avoided by increasing the strength of the solution, which, I infer, has been found impracticable, because of increased pain or other reasons. The object can be attained by incorporating iodoform in the solution to be used, and thus combined, the anæsthetic effect of the guaiacol is increased and prolonged. The formula that I have adopted after a number of trials as most eligible is as follows:

℞.—Eucalyptol, pure . . . . 32 minims.
Guaiacol, pure . . . . 16 "
Iodoform . . . . . 8 grains.
Iodine . . . . . 4 "
Ol. amygdal. dulc. (sterilized) q. s. ad 1 ounce.

Sig.—For hypodermatic use; 10 to 30 minims daily, or alternating with gold and sodium solution, as desired.

The anæsthetic properties of this solution are such that patients prefer its use to that of the gold solution, although the latter is nearly painless. Larger doses of the guaiacol and eucalyptol than is contained in the thirty minims of the above solution have, in my hands, caused excessive and exhausting sweating, with no proportionate benefit. The amount of iodine in this formula is the same as that contained in the Shurly-Gibbes solution, with, as will be seen, double that quantity of iodoform. Therefore the dose may be but one-third to one-half of that of the Shurly-Gibbes solution.

A CASE OF ANTE-PARTUM HOUR-GLASS CONTRACTION.

BY W. H. F. MILLER, M.D.,
OF CLIFTON FORGE, VA.

THE following is a brief report of a case of this very rare condition: On the evening of May 31st I was sent for to see Julia N., a mulatto, aged twenty-two, a primipara, who was in labor. On examination I found a left occipito-anterior presentation, with the os dilated to about the size of a twenty-five-cent piece. I left word that I would return in about an hour. Upon my return at about 10 o'clock I found the os as large as a fifty-cent piece and the pains irregular. I gave ten grains of sulphate of quinine, and retired to another room, telling the nurse to call me as soon as the character of the pains changed. About half-past twelve I was called and found that the second stage had set in, the pains being still slow and irregular, but decidedly expulsive. In half an hour the occiput was well into the inferior strait. During the next half-hour there was no advance whatever, though the patient appeared to have good pains. An examination did not show any cause for the arrest of the fœtus, either from abnormal parts in the mother or a too large head in the child. I therefore looked elsewhere, and found that during a pain the womb was divided into two spherical parts by a constriction about the middle, the two parts being about the same size. The constriction was constant, but the tension was increased during the pains. The fundus of the womb did not contract at all, and, as far as I could make out, the only change in the womb during the pains was the tightening in a transverse direction of this band of muscle. I applied one hand to the fundus and, for about fifteen minutes, pressed downward during each pain, but without any appreciable advance of the head; failing with moderate pressure to elicit any response from the womb, I stood up, and with each pain I placed both hands on the fundus and pressed downward and forward with as much force as I dared employ. The result was that after one or two pains the head began to advance and the womb contracted normally, except that the segmentation was very distinct even at the height of the pain. I left off pressure just as the head was ready to pass over the perineum, but the fundus again failing to act, I again continued the pressure, and the child, a medium-sized girl, was born in a few minutes. I examined the womb carefully after the end of the second stage, but could find no difference from the condition of the womb in an ordinary case. Slight traction on the cord, combined with expression, brought away the placenta without any trouble. The woman made an uninterrupted recovery.

Hour-glass contraction in the third stage of labor is a very common occurrence, and in these cases we have a contraction about the internal os; but in the case I have reported the contraction was at the centre of the body of the uterus. It seemed as if someone had a stout cord tied about the womb and that at stated periods the ends were drawn taut. There was, of course, no expulsive effect to the contractions, because the muscles merely seized the child and held it fast, thus rendering any advance impossible. I believe that only a single fasciculus of the circular muscles took part in these contractions, as the band was very narrow. The fundus, except under the stimulus of violent pressure, was inactive, yet after delivery the whole womb contracted very nicely. Of course, I expected to have difficulty in the third stage, yet there was no apparent extra contraction at the internal os. I gave ergot when the head was born, and this may have caused a regular contraction.

A METHOD OF CONTROLLING UTERINE HEMORRHAGE.

BY BRUCE PEDEN, M.D.,
OF BLOOMFIELD, ARKANSAS.

AFTER having vainly tried all ordinary methods, such as the employment of ergot, injections of astringents, etc., I recently controlled a severe case of uterine hemorrhage

by the following method: I took an ordinary rubber condom and introduced into it an ordinary male catheter, fixing the open end of the condom securely around the staff of the catheter by wrapping it several times with stout thread. I then adjusted a common syringe to the catheter and introduced the latter, carrying with it, of course, the condom, into the cavity of the uterus up to the fundus. This left the lower end of the rubber bag about on a level with the external os. I then proceeded to inject water into the cavity of the condom, speedily checking all hemorrhage. I could not have wished for a better result. I think this will be found a valuable means of arresting uterine hemorrhage by all who will give it a trial.

I shall try this method of arresting post-partum hemorrhage, by having a suitable apparatus made upon the same plan, with a larger bag, etc., and have the catheter of rubber, so that it can be left in position without inconvenience. The bag could, of course, be inflated with air, hot or ice-water, if necessary; in the first instance avoiding the weight of water, in the latter getting the benefit of heat or cold, as desired. The contents of the bag could be allowed to escape gradually, thus permitting the uterus to contract by degrees. The bag could be left in position for a considerable length of time without danger. I think this will have several advantages over intra-uterine tamponnement by means of strips of gauze, as suggested in THE MEDICAL NEWS of January 24th.

A NEW USE FOR ARISTOL.

BY JAMES J. LEVICK, M.D.,
OF PHILADELPHIA.

IN a case of poisoning of the hands from *rhus toxicodendron*—poison oak—recently under my care, which had reached the vesicular stage and was attended with much swelling and burning, the happiest results promptly followed the free dusting of the powder of aristol on the affected parts. The change was almost magical, so sudden and so prompt was the relief afforded. Might not this powder, applied in the early stage of the disease, do much toward preventing the ulceration and pitting of variola?

1200 ARCH ST.

MEDICAL PROGRESS.

For Vomiting after Chloroform Inhalation.—LENEWITSCH (*Med. Obstet.*, No. 1, 1891) succeeded in checking the obstinate vomiting in six cases following chloroform-narcosis by washing out the stomach with a one-half to two per cent. solution of soda. Not only was the vomiting at once controlled, but the general condition also improved.—*Centralbl. für Chir.*, May 23, 1891.

Primary Erysipelas of the Tongue.—GAREL (*Annales des Malad. de l' Oreille, etc.*, May, 1891) reports the case of a laborer, thirty-seven years old, who presented considerable swelling of the tongue which began at the anterior half, at a point of ulceration, the result of the influence of a carious tooth. The swelling was so great that the patient could not close the mouth, and there was profuse dribbling of saliva. In addition, there was a sense of debility, headache and fever. In the course of a few days the pharynx, and in succession, the cheeks, the nares, the eyelids, the ears and the scalp became involved.

Pleuritic Effusion containing the Bacillus of Eberth.—FERNET (*La Médecine Moderne*, May 21, 1891) reports the case of a boy of seventeen, who, two months after an attack of typhoid fever, developed a pleurisy, with serofibrinous effusion, in which the bacillus of Eberth was detected. In five other cases of pleurisy associated with typhoid fever, the bacillus was not found. Nevertheless Fernet believes that, in all, the pleurisy was dependent upon the bacillus of Eberth, and proposes the name typhoid pleurisy.

Hæmaturia due to Distoma Hæmatobium.—At a recent meeting of the Berlin Medical Society, NITZE (*Prager medicin. Wochenschr.*, May 13, 1891) presented a boy, with vesical tenesmus and burning micturition of a cloudy urine containing red and white blood-corpuscles, pus-cells and the characteristic ova and living embryos of the distoma hæmatobium. The boy, as well as two brothers who suffered similarly, had lived in Africa. A tumor in the bladder of the eldest brother, a result of irritative proliferation from the presence of ova, was removed by a supra-pubic operation; the subsequent improvement was only temporary, as the actual cause of the disorder is constituted by the presence of living distoma in the portal vein or in the perivesical veins.

The Influence of Epilepsy upon Secretion.—FÉRÉ (*La Méd. Mod.*, May 21, 1891) relates the case of an epileptic woman, nursing an infant, in whom withdrawal of the bromides was followed by a return of the seizures and cessation of lactation.

The Treatment of Aneurism of the Aorta by Potassium Iodide.—BALFOUR (*British Medical Journal*, June 6, 1891) details one case of aneurism of the aorta and makes reference to several others in which most satisfactory curative results were obtained by the administration of potassium iodide. To cure or even to improve an aneurism by the administration of the iodide the patient must not be starved, but must be well fed. The cure is effected by an hypertrophy of the walls of the sac, not by coagulating the blood within the sac, and is interfered with by lowering the nutrition. The iodide may possibly have some effect in producing hypertrophy of the fibrous tissues; indubitably, its most important effect is to cause a permanent lowering of the intra-arterial blood-pressure. To obtain so important a result it is not necessary to give the iodide in large doses. The proper course to pursue is to put the patient in the recumbent posture for several days, so that the normal pulse in recumbency shall be five or more beats lower than in the erect posture. Five grains of potassium iodide (sodium iodide has not the same effect) in some bitter infusion are given every eight hours, the pulse-rate being carefully observed daily at a stated time; after two or three days the dose of the iodide is increased to ten grains every eight hours. In this way the dose may be gradually increased until the pulse-rate is observed to rise; then the administration is withheld for a day and the previous dose resumed. As soon as the pulse-rate increases, the benefit ceases and the constitution begins

to suffer. But seldom is it necessary or advisable to increase the dose beyond ten grains every eight hours; commonly enough five grains suffice. The maximum of benefit is obtained from a dose just below that which lowers the blood-pressure so far as to cause the pulse-rate to rise. The remedy is administered every eight hours for two or three months. At the end of that time it need be administered but every twelve hours. The length of time the remedy should be continued depends upon the size of the aneurism when the treatment was begun. At least from three to six months are required to make the patient comfortable.

The Determination of the Number of Bacilli in Tuberculous Sputum.—Dissatisfied with the current methods of counting the number of bacilli in the sputum of tuberculous patients, NUTTALL (*Bulletin of the Johns Hopkins Hospital*, May–June, 1891) has devised a means for which he claims simplicity and accuracy. The total amount of sputum expectorated during twenty-four hours was caught in covered, scrupulously clean, conical glasses. According to the degree of viscidity of the sputum, a varying amount of 5 per cent. caustic potash solution was added to it (from one-sixth to an equal volume); after the sputum was rendered perfectly fluid, water was added to dilute the mixture. The sputum was then poured into a perfectly clean, wide-mouthed bottle containing fine (sterilized) gravel or broken glass. The conical glass was then rinsed out and cleaned of any still-adhering sputum by means of a measured amount of the caustic potash solution, which in turn was added to the sputum in the bottle. The latter, closed by a rubber stopper, was then transferred to a shaking machine, in which it was vigorously shaken for five minutes and then allowed to stand until the caustic potash had had time to act. Very viscid sputum was then warmed at body-temperature. As soon as the caustic potash had rendered the sputum homogeneous a measured quantity of water, usually an equal volume or less (preferably distilled), was added and the mixture again shaken. The sputum having stood for from two to four hours, was again shaken for from five to ten minutes. By means of a special apparatus, drops of the mixture of approximately equal size were spread upon cover-glasses, dried and surrounded by a delicate ring of a paint composed of lamp-black and serum. Over all was sprayed a thin film of diluted serum, which was fixed by heating the cover-glass at a temperature of from 176° to 194°. The caustic potash was extracted by alcohol. The specimens were stained with the Ziehl-Nielsen carbolized fuchsin and decolorized by alcohol and a mixture of water, 150 parts, alcohol 50 parts, and sulphuric acid from 20 to 30 drops. In counting, a square diaphragm, with an eccentric hair-line, was used with the eye-piece of the microscope. The fields were controlled by the use of a revolving disc in connection with the screw of the mechanical stage. Recording was facilitated by means of an automatic register. The method promises to be useful also in the study of bacterial cultures.

Œsophagotomy for the Removal of a Tooth-plate Long Impacted in the Œsophagus.—FURNER (*Lancet*, May 2, 1891) has reported the case of a woman, forty-four years old, in which, five and a half years before, a tooth-plate had slipped into the œsophagus. There was dysphagia of varying degree and occasional dyspnœa. A probang introduced into the œsophagus encountered an obstruction ten and a half inches from the teeth. Attempts to remove the plate by means of forceps were unsuccessful. Three months later œsophagotomy was performed. A portion of the plate was imbedded in the wall of the œsophagus. Considerable traction was required to bring the plate away. About an ounce of arterial blood escaped after the removal. No nourishment was given by the mouth during the first two days, but four ounces of pancreatized beef-tea were administered per rectum every four hours. On the third day an attempt was made to introduce food into the stomach through an elastic catheter passed from the mouth, but the milk was rejected. The attempt was repeated on the fifth day with a like result. On the evening of the fifth day the patient was raised in bed, and leaning slightly forward, was given milk to drink, which she swallowed and retained. Recovery now progressed favorably. On the twenty-first day after the operation the patient swallowed bread and milk; on the twenty-fourth day she took fish; on the twenty-eighth day the wound was healed.

Pilocarpine in Labyrinthine Disease.—In a paper read before the Philadelphia County Medical Society, DR. S. MACCUEN SMITH stated that he had treated with subcutaneous injections of pilocarpine hydrochlorate forty-seven cases of a greater or less impairment of hearing —in some there being almost entire deafness. The dose usually employed was one-sixth of a grain, although one-fourth of a grain was frequently necessary. In view of the possible danger to life in administering full doses of pilocarpine, some authorities advise the use of atropine or strychnine in conjunction with pilocarpine. This is a proper and safe precaution, and should be employed in suitable cases; yet in the greater number this was not found essential. As patients cannot usually stand the daily injection, an injection was made every second day, it always being *insisted* on that the patient remain *in bed* for from three to five hours after each injection, as the resulting perspiration continues for that length of time, and any undue exposure or exertion may cause unfavorable symptoms. The injections are continued until five, eight or ten have been given, and then, if additional ones are required, they may be administered at intervals of from five to ten days, as the symptoms indicate. As a result of his observations Dr. Smith has arrived at the following conclusions: Age and sex have no influence on the success or failure of the treatment of labyrinthine disease by means of pilocarpine, subcutaneously; in recently developed deafness, with tinnitus, this mode of treatment is much more promising of success than in cases of longer duration; cases of chronic suppurative otitis media, with some degree of impaired hearing, resulting from the exanthematous fevers, are not proper cases for treatment by this method; deafness, vertigo and tinnitus, in the course of syphilis, seem to be especially benefited by the subcutaneous injection of pilocarpine; good results can only be obtained from the full physiological effect of the drug; profuse diaphoresis must be obtained in every case.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JULY 25, 1891.

THE AMŒBA COLI.

THE interest of the subject of rhizopods as parasites has of late years received an important impetus from the study of the amœba of dysentery, or, as it has been designated, the amœba coli. The credit of first observing amœbæ in stools is due to LAMBE, who described such organisms that he had found in the dejecta of a child suffering with dysentery; but to LÖSCH belongs the credit of establishing these as definite parasitic organisms. The investigations of LAMBE, published in 1852, seem to have called forth no comment, excepting from LEUCKART, who, in his work on animal parasites, referred to them, but regarded the objects seen as merely altered intestinal epithelium. In 1873, however, LÖSCH, at St. Petersburg, discovered in the stools of a case of dysentery, amœbiform organisms resembling those of LAMBE; but, after a description that to this day stands as a model of scientific accuracy, concluded that the amœba he had discovered was different from that of LAMBE, and from its seat in the colon he named it the *amœba coli*. After a lapse of another ten years the subject was revived by KARTULIS, at Alexandria, and since his first publication in 1885 reports extending and confirming our previous knowledge have been made in all parts of the world. In Italy, GRASSE, PERRONCITO and LONTINO; in Austria, KLAVA; in India, CUNNINGHAM and LEWIS; in Germany, KOCH and GAFFKY; and in America, OSLER, COUNCILMAN and others—have each added facts of interest in the study of this organism.

Biologically the place of the amœba is not definitely fixed, nor can this indefiniteness be cleared up until a fuller knowledge of its cycle of life within and without the human body has been obtained. So much, however, may be taken as definitely determined, viz.: that we have to deal with an amœba distinct in all important characteristics from the other members of its family; and as to habitat it is probably never observed outside the living body and in the excretions of man and a few animals. According to LÖSCH, the most closely allied form is the *amœba princeps*, which differs in size, movements, and chemical reactions from the amœba coli. The size of the amœba coli varies from 19 to 35 μ, that of the amœba princeps from 20 to 60 μ; the pseudopodia of the amœba coli are projected and withdrawn in the same line, those of the amœba princeps are returned by a movement along the periphery of the body, with reduction in size until the pseudopod has entirely disappeared; by alcohol the nucleus of the amœba coli is made less visible, that of the amœba princeps more visible. These facts, with the added observation of a peculiar flowing of the granular protoplasm toward and into the pseudopodia, and a common vacuolation and distinctive granulation, render it certain that this organism is one hitherto unknown and undescribed. No further facilities appear to have been afforded LÖSCH for the continuation of his studies, and it remained for KARTULIS to utilize the abundance of material at Alexandria, and to clear up several important points in the life-history of the organism. Convinced by the uniform occurrence of the amœba in large numbers in the stools of tropical dysentery that there is more than mere coincidence or passive agency in this, he was in his subsequent labors led to study the stools of other diseases, and also to make experimental investigations as to pathogenicity. His statement (*Virch. Arch.*, Bd. cxviii. S. 97) that he has found the amœba in 500 cases of dysentery, but never in any other disease, should it receive confirmation from the investigations of others, will, if nothing more, go far toward establishing diagnostic value. But we must here interject the testimony of MASSINTIN, who, working

in the laboratory of LÖSCH, at Kigen, found amœbæ in the stools of five cases of various intestinal diseases not regarded as dysenteric; and, at the same time, we may add that the claim of KARTULIS that the finding of these forms is sufficient to establish the diagnosis of dysentery, is, in the present state of our knowledge, not warranted.

As to pathogenicity, it is of interest to note the recent statement of COUNCILMAN, that as in pneumonia, so in dysentery, there may be a variety of causative agents; and, consequently, if in certain cases the amœba be proved absent, in others it may still have great significance.

The anatomical distribution of the organism is also suggestive. First seen in the stools, it was next discovered in an intestinal ulcer by LÖSCH, in the pus of liver abscess by KARTULIS, in the bloodvessels of the liver by KOCH, and finally in the expectoration of cases of liver abscess and diaphragmatic perforation by OSLER. These facts, and the uniformity of their occurrence, together with the common observation of bacteria, blood corpuscles, and all manner of débris within the amœba, lends some probability to the view of KARTULIS that liver abscess results from a migration of the bacteria-laden amœbæ through the blood-paths into the liver. But little is proved as regards the causation of the dysentery, and in no sense do the facts warrant the further assumption of KARTULIS that the pyogenic bacteria thus transported to the liver can excite suppuration only in areas degenerated and prepared for suppuration by the action of the amœbæ.

Of great interest and value are the experiments on animals. By injecting *per rectum* mucus from the stools of his case, LÖSCH was able to set up gastro-intestinal disorder in one of four dogs, and he found in the excreta of this animal large numbers of the amœbæ that had previously been wholly absent. Latterly KARTULIS has succeeded in producing experimental dysentery in cats by similar injections with mucus of the dysenteric stools, as well as with pure (?) cultures of the amœbæ which he has obtained in straw decoctions. He failed in dogs, guinea-pigs and other animals. These experiments, though highly interesting, cannot be considered demonstrative, because they fail in the non-exclusion of other organisms that may have been injected at the same time with the amœbæ; and they also fail from want of uniformity in the results obtained.

A careful and unprejudiced review of the literature of this subject would seem to indicate the probable pathogenic significance of the amœba coli, and it may be credited with a diagnostic value of a fair degree of certainty. It may be added that at least in one case its presence has made it possible to diagnosticate an unsuspected liver abscess, and in similar cases it may hereafter prove of like value.

THE ADVERTISER.

IF it be thought extreme to say that the medical profession in the United States is at the parting of the ways as regards the adoption or rejection of advertising practices by the physician, it cannot be held an exaggeration to say that a certain number of the members of that profession are always a little more than ready to take the left-hand road. Slyness, cunning, the ease of concealment of indirect methods of advertisement, perhaps also a general lowering of ethical standards, make it progressively more difficult to deal with those who combine an itching for public notice and selfish gain with a deplorable want of self-respect and professional honor.

We all know them perfectly well—these fellows that get themselves and their doings into the daily papers—and we understand exactly how the reporters get possession of the facts. It is the men of a certain well-understood type of character that are thus deceived by their hospital-residents and the enterprising reporters. The honest man has no difficulty in shutting off the reporters and controlling his assistants. We know also that they cannot be caught, and they themselves know it quite as well. Moreover, it is equally well known that those who have the ability to put a stop to advertising have not the moral courage to do it. It is a strange lethargy—a sort of sleeping-sickness that seems to deaden the professional conscience and hide from it the seriousness of its disease. There are to-day two or three fatal tendencies benumbing and dragging us toward ruin—the hospital-abuse, the compromise with open quackery outside, and with concealed quackery inside the profession. But circulating in the body professional there is a more subtle poison, and one far more dangerous than either of these. This is the rule-or-ruin policy of men intellectually and immorally strong. It is but another outcropping of the dominance of the modern hotly-pursued ideals of shrewd greediness united with unscrupulousness—ideals that are ruinously active in political and mercantile life.

In medicine it is distinctly a new phase, and one that it were better to estimate at full value. It must be squarely met and judgment decisively pronounced upon it. Early in his medical life a man will range himself with one party or the other; consciously or unconsciously he will join the party of the scheming pushers or the party of the honest workers. *Gleich und gleich gesellt sich gern.* The success of one unscrupulous politician debauches by example a hundred imitators, and concealed or brazen advertising becomes an art cultivated with persistent zeal. The novel aspect of the case consists in the fact that this species of advertiser is not scientifically a fraud or a quack, but it is a part of his stock-in-trade to be well abreast of scientific progress. He will swim with the tide, adopt the pseudo-scientific craze of the hour, even profess the greatest interest in genuine medical science, cultivate technical skill, and so forth. All this looks to success, and success, regardless of means and methods, is his sole aim. To reach it he will "wire-pull" himself into official positions, become a teacher, professor, visiting physician to hospitals, and finally spread the reports of his cures and wonderful surgical operations before the admiring gaze of the gaping newspaper-reader. The young physician looks on amazed that the censors of medical societies to which the advertiser belongs ignore these facts, and the young man says it is only the little fellows, they who need it most, that dare not advertise, and the young man at once resolves that the rule shall mighty soon be circumvented. In the meantime the "Boss TWEEDS" of medical politics are asking with ever bolder effrontery, "What are you going to do about it?"

Let us emphasize the patent fact that the evasion of action, the shirking of evident duty, and the permission of silence will never cure the evil. It is upon this cowardice that these cunning schemers count, and it is the condition of their success. As we all know, there is one way and only one way of making an end of all this. The respect or the supposed respect and comradeship of one's fellows and equals is at once the motive of true ambition, and in this case the absolute *conditio sine qua non* of professional success. Expel a few of these advertisers from honorable medical societies and there will be a sudden change in their manners and their methods of achieving professional success. Seeming harshness in such cases is not real harshness; it is for the final good even of the advertiser himself.

ALCOHOLISM.

THERE are extremists upon all debatable questions. The truth, however, can be arrived at only by impartial discussion and broad observation. It should not be perverted by blind fanaticism, nor should it be obscured by ignorance. Illiberalism is a bar to progress, and can only result in evil.

There are well-meaning persons who insist upon calling the excessive use of alcohol disease. It were as justifiable to similarly designate excessive smoking, or the persistent, injudicious indulgence in a favorite article of diet. Indolence, theft and immorality are as much diseases.

The excessive use of alcohol may be considered a morbid habit, in the same way as is the addiction to morphine, or opium, or cocaine, or tobacco, or coffee, or tea. The results of the habit and the sequelæ to which it gives rise must not be confounded with the influences that lead to the habit.

Apart from all prejudice, alcohol has legitimate uses. It is a valuable medicament. Properly administered, in conditions of low vitality, it is not merely a useful stimulant; it is also a valuable food, its efficacy depending upon its ready combustion and the production of force.

It were as rational to banish from the materia medica opium or strychnine, or caffeine or cod-liver oil, as to exclude alcohol; but it may be added that the materia medica is the exclusive place for the agent. Like most medicaments, it is powerful for evil as well as for good, and its administration should be under the control and guidance of competent persons. Its indiscriminate use should no more be permitted than should that of opium or strychnine.

That even the medicinal application of alcohol is abused cannot be contradicted. The same criticism may be applied as well to digitalis and to opium, but no one would ask that the use of these be proscribed and none would claim that their excessive use was an evidence of disease.

Recognizing the far-reaching evil results to which the injudicious, or even the judicious, administration of such medicaments as alcohol, opium, morphine, cocaine, chloroform and ether may give rise, the physician must exercise the wisest discretion in the use of any and of all of them.

From the social and economic point of view the remedy for the abuse is as difficult as is that for the excessive use of tobacco or for prostitution.

CORRESPONDENCE.

HOMŒOPATHY.

To the Editor of THE MEDICAL NEWS,

SIR: In reference to your editorial article on the "Homœopathic Convention," which informs your many readers that THE MEDICAL NEWS has decided opinions concerning homœopathists, I wish to draw your attention to a few undeniable facts.

Let any scientist carefully study the steady advance of medicine during the last century, and especially the last decade; let him note the progressive march toward that goal, so much desired, so much fought for by all medical minds, the establishment of medicine as a science, combined with the art to carry out its dictates—and he must acknowledge that of all the eminent men that have led us in this earnest search for truth, not one was a homœopath. Whether we enumerate the instruments of precision to-day employed in the investigation of disease, whether we take up the astonishing results obtained by modern physiological study, or whether we let pass before our view the "dawning of the new day," the revolution in the pathogenesis of infectious disease, we must invariably answer the question, *Did a homœopath contribute one iota to these successes?* with an imperative, *No!* The stethoscope, the self-registering thermometer, the sphygmograph and all the many instruments of precision enabling us to note the slightest deviation from health, were invented by regular physicians. The profound researches that led to the demonstration of the ptomaïnes and toxalbumins, that showed us the intricate metabolic process underlying the function of each individual cell, the wonderful unravelling of the network of paths, apparently so confused and yet so clear and definite, uniting the cortical centres and all the ganglia with every part of the animal organism depending upon them—did a homœopath participate in the minutest portion of them? No.

And when we finally come to bacteriology, the latest addition to our science, yet small but destined to cause the greatest revolution ever set in motion in any branch of human knowledge: who proved to us the cause of infectious diseases? Who made the first step in the direction that is bound to lead us to the total prevention and the complete cure of those zymotic diseases which have decimated mankind for thousands of years? No homœopath, for certain.

But read their journals, watch the proceedings of their debates! They adopt the results of our researches and make use of our discoveries without the least right and without hesitation!

Has there ever been an instance in which any result obtained by homœopaths in their so-called investigations has been adopted by the regular profession? Can anyone name any invention, any discovery, anything that proved a boon to humanity, that became the property of the whole civilized world, that has originated in homœopathy?

Only one principle—*similia similibus*—brought them adherents. And if we remember, that in its application Hahnemann quoted the itch and advised, therefore, the powdering of the crusts that developed in consequence of the scratching, and the infinitesimal dilution of this powder used internally as the sovereign remedy against a disease that *our* research soon after proved to be due to a parasite, easily destroyed by a little potash, soap and sulphur, it must appear as an outrage to real science to allow the promulgation of such nefarious theories. What would sensible people say to-day, if a child had lice and we gave the powdered lice and the dandruff, etc., internally as a remedy for the lice? That is exactly Hahnemann's method in the itch!

There is but one way out of the difficulty—we must feel and show our contempt for homœopathy. It is a humbug from beginning to end and will die a natural death. The more we advance in our science—and indeed we are making giant strides—the higher the education of the population, the longer the term for the study of medicine and the severer and the more impartial the State Board examination of candidates for the right to practise, the quicker homœopathy and all other dogmatic -pathies will die.

Name one eminent mind in the medical fraternity, whose name is known all over the world, who has ever become a homœopath. And of all the homœopaths who have become known in the small circle of their immediate neighborhood or in their own homœopathic boundaries, name me one who has achieved something greater than Dr. Hering, who used to be looked upon by his confrères as their most illustrious representative, and whose main achievement was the discovery of the magnetic influence that shows itself in practising the following procedure:

Some infinitesimal dose, say the millionth part of a drop of the tincture of aconite dissolved in a glass of water will have the best effect if the glass be held in the *left* hand while we have full moon and the diluted stuff be then slowly sipped!

It is ridiculous, horrible, to think of it. No wonder that they have nothing to say in their conventions except about laws that may insure to them a longer life and do away with the necessity of study. Take any body of learned men and bring before them a physician and a homœopath. Let the latter tell all that he knows of the pathogenesis, the pathology, the symptoms and course, and the treatment and prophylaxis of tuberculosis, provided it be stipulated that he cannot draw upon the knowledge gained and discovered by the true medical profession *after* Hahnemann's death, and then give the physician the same opportunity! What would be the judgment of such a jury?

HUGO ENGEL.

NEWS ITEMS.

The American Dermatological Association will hold its fifteenth annual meeting at Washington, D. C., September 22, 23, 24 and 25, 1891.

The following papers will be read:

FIRST DAY.—SEPTEMBER 22D.

Dermatitis Hæmostatica, by Dr. H. G. Klotz.

A Case of Lupus Erythematosus with Fatal Complications, by Dr. W. A. Hardaway.

Report of a Case of Universal Erythema Multiforme, with colored portrait and specimen, by Dr. L. A. Duhring.

An Unusual Case of Sarcoma involving the Skin of the Arm; Amputation; Recovery, by Dr. F. J. Shepherd.

Multiple Sarcomata: History of a Case Showing Modification and Amelioration of Symptoms with Large Doses of Arsenic, by Dr. S. Sherwell.

SECOND DAY.—SEPTEMBER 23D.

Discussion on Tuberculosis of the Skin:

Its Clinical Aspects and Relations, by Dr. J. C. White.

Its Pathology, by Dr. J. T. Bowen.

Its Treatment, by Dr. G. H. Fox.

Thirteen Cases of Tuberculosis of the Skin, with their Treatment, by Dr. J. S. Howe.

A Case of Lichen Scrofulosorum, by Dr. J. Grindon.

Notes of a Visit to the Leper Hospital at San Remo, Italy, with Photographs, by Dr. L. A. Duhring.

THIRD DAY.—SEPTEMBER 24TH.

The Treatment of Alopecia Areata, by Dr. P. A. Morrow.

A Therapeutic Note on Alopecia Areata, by Dr. L. D. Bulkley.

Morphœa Atrophica of Wilson, by Dr. R. W. Taylor.

The Treatment of Pruritus, by Dr. E. B. Bronson.

Prairie Itch, by Dr. L. N. Denslow.

Diseases of the Skin Associated with Derangements of the Nervous System, by Dr. W. T. Corlett.

Treatment of Chronic Ringworm in an Institution for Boys, by Dr. L. A. Duhring.

FOURTH DAY.—SEPTEMBER 25TH.

Notes of a Case of Acute Dermatitis Exfoliativa, by Dr. J. E. Graham.

Note Relative to Pemphigus Vegetans, by Dr. J. N. Hyde.

A Study of Mycosis Fungoides, with Report of a Case, by Drs. H. W. Stelwagon and H. Leffingwell Hatch.

Lymphangioma Circumscriptum, with Report of a Case, by Dr. M. B. Hartzell.

Remarks on Carbuncle, with Report of a Peculiar Case, by Dr. H. G. Klotz.

Note on Erythema et Nævus Nuchæ, by Dr. C. W. Allen.

A Case of Lichen Ruber, by Dr. J. Grindon.

The Personal Equation in Dermatology, by Dr. L. D. Bulkley.

The American Orthopedic Association will hold its fifth annual meeting at Washington, D. C., September 22, 23, 24 and 25, 1891.

The following programme is announced:

FIRST DAY.—SEPTEMBER 22D.

The President's Address, by Dr. A. B. Judson, of New York.

The Orthopedic Work of the Late Mr. Thomas, by Dr. A. J. Steele, of St. Louis.

Uniform Nomenclature in Orthopedic Surgery, by Dr. W. R. Townsend, of New York.

Two Cases of a Peculiar Type of Primary Crural Asymmetry, by Dr. Henry Ling Taylor, of New York.

On the Best Means of Preventing a Loose Joint, or Dangling Limb, after Resection at the Shoulder-joint, with an Illustrative Case, by Dr. W. R. Whitehead, of Denver.

A Case of Spina Bifida with Partial Motor and Sensory Paralysis, Double Equino-varus and Purulent Bursitis, by Dr. H. Augustus Wilson, of Philadelphia.

Congenital Club-foot, with Absence of Great Toe and Contiguous Bones of the Instep, by Dr. T. M. L. Chrystie, of New York.

A Case of Club-foot, Club-hand and Multiple Joint-deformity, by Dr. William E. Wirt, of Cleveland.

On the Use of the Wrench in the Treatment of Club-foot, by Mr. Robert Jones, of Liverpool.

Operation upon the Concave Surface in Talipes Equino-varus, by Dr. B. E. McKenzie, of Toronto.

The After-treatment of Excision of the Knee-joint, by Dr. John C. Schapps, of Brooklyn.

Gonorrheal Rheumatism and its Treatment—Primary and Secondary, by Mr. B. E. Brodhurst, of London.

Atrophy in Joint Disease, by Dr. E. G. Brackett, of Boston.

The Diagnostic and Prognostic Value of High Temperature in Chronic Joint Disease, by Dr. Robert W. Lovett, of Boston.

MOTOR DISTURBANCES OF THE STOMACH.[1]

BY CHARLES G. STOCKTON, M.D.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE, MEDICAL DEPARTMENT OF THE UNIVERSITY OF BUFFALO; PHYSICIAN TO THE BUFFALO GENERAL HOSPITAL.

THE object of this note is to re-state the importance of the systematic study of gastric disorders. The symptoms produced by the various indigestions naturally arrange themselves into those of unnatural sensations, abnormal secretions, and irregular movements. Of these last, those that are dependent upon functional rather than upon structural fault are here considered.

Possibly too little attention is given to the question of the gastric movements in the process of digestion. Our efforts are more often put forth for the correction of faulty secretion, but good thus accomplished is often produced by effects upon the motor functions of the organ. For instance, in infancy, children frequently regurgitate milk soon after nursing, and this to such an extent that the child suffers from inanition. It is noticed that the milk returned is curdled and acid in reaction; the fault is attributed to an acid stomach, and alkalies are given, with consequent relief. Now, probably in such cases the stomach is not too acid, but rather the cardiac orifice relaxes, and when the normal peristalsis of the stomach occurs regurgitation of the food takes place. The effect of the antacid, lessening the stimulation to the gastric walls, is followed by a weaker peristalsis; the cardiac opening does not relax under the weakened pressure, and the trouble abates. A similar condition of affairs takes place in adult life, and many persons suffering from what they call sour stomach will, upon careful investigation, be found not victims of true pyrosis, but rather of weakness of the cardiac orifice which permits too easy regurgitation of the stomach-contents. It is to be understood that when the movements of the stomach are properly balanced, there may be sufficient stimulus from fermentation, or other abnormal conditions of the gastric contents, to produce unnaturally strong peristalsis, and hence regurgitation. In such cases, the food returned will be very irritating, probably very acid, and will be accompanied by other symptoms than those of motor disturbance.

[1] Read before the Medical Association of Central New York, June, 1891.

In other cases it will be found that the gastric contents are excessively acid in reaction, and so irritating as to produce gastric catarrh, and yet regurgitation does not take place. In other words, the cardiac orifice once closed remains securely locked, and fails to open to any degree of pressure or stimulation from below. Hence patients may suffer from sour stomach and not know it; and, on the other hand, paradoxical as it may seem, may be actually free from pyrosis while yet complaining of acid eructations. I have reported one case in which a young woman was reduced to the verge of starvation from the continued return of food, and this without any other apparent disturbance of digestion; without nausea, without vomiting—quite after the manner of the ruminant.

Your attention is invited now to similar perversions in the behavior of the pyloric orifice. All of us are familiar with lienteric diarrhea, and frequently have had patients complaining that immediately after eating they were hurried from the table by an urgent desire to evacuate the bowels. On inspection of such alvine discharges, the food is found to be but little changed, and, as a result of this, nutrition fails, as is evidenced by the loss of flesh and the accompanying nervous phenomena. Efforts to correct this by ordinary remedies for diarrhea are attended with poor success, but remedies directed toward calming the peristalsis and strengthening the pylorus, if administered immediately before meals, will result in removing the difficulty. The cause of this diarrhea is doubtless a weakened pylorus. It usually occurs in neurotic individuals the digestion of whom is without fault, except in this simple irregularity of the gastric movements. In these cases, there must also exist a similar disorder in the intestinal movements, which is fortunate, for the reason that it points out the seat of trouble. I have seen several cases in which the stomach was completely emptied of a hearty meal within an hour after its ingestion. This food cannot be sufficiently prepared for entrance into the intestine; its presence there must create intestinal disorders, and, in fact, is a common cause of duodenal indigestion and intestinal catarrh.

On the other hand, the pylorus refuses to relax at that proper period of digestion and of time appointed by Nature. Such a condition is illustrated by a case that I now have under observation. This young man has a good appetite, eats heartily, suffers no

distress for several hours after his meal; then he feels a sense of weight and fulness in the epigastrium, general nervousness, and sometimes gastric pain preventing sleep and business pursuits; these symptoms are entirely relieved by emptying the stomach by means of a tube. If this procedure is carried out not too long after eating, the meal is found to be properly digested, apparently ready for passage onward; if too long after a meal, an excess of fluid is found. Before treatment, this disturbance had led to a somewhat acute dilatation, and, indeed, on several occasions three quarts of fluid were removed from his stomach at once, after which he was perfectly comfortable, and ready for another meal. Not only was there abnormal tightness of the pylorus, but doubtless of the cardia likewise, for through his thin abdominal wall the violent gastric movements could be plainly observed in slow, strong undulations; the stomach evidently vainly struggling to empty itself. The bowels were constipated, the skin dry, the urine scant, not albuminous (save a faint trace by picric acid), but containing hyaline and granular casts in large number. Treatment directed to the nervous system, to lessening the arterial tension, and to stimulating the skin, with very little local treatment of the stomach, quickly relieved his symptoms. The stomach resumed its natural size, defecation became regular and natural, the urine became normal, and, according to my own scales, he gained fourteen pounds in ten days. I have no doubt that this condition to some extent explains the cases of marked dilatation of the stomach not depending upon stenosis in the ordinary sense of that term.

This seems a proper time to speak of the want of gastric peristalsis which so often results in retarded digestion, and occasionally gastrectasia. In the majority of cases of gastric dilatation coming under my observation there has been great atony of the walls with almost complete absence of movement. In advanced cases the tight closure of the orifices is not seen, gas is passed freely upward, and I have no doubt the fluid contents would pass easily downward but for the fact that the stomach is dilated into a great sac, lying so far below the pylorus that, without gastric movements, complete emptying of the organ is not naturally effected. Time does not permit of the consideration of vomiting, spasm of the stomach, and irregular peristalsis, which might properly be treated under this head. I have only time to speak briefly of the management of these cases. The measures employed in their treatment consist in careful diet, regulation of the gastric stimulation, the application of electricity by means of the gastric electrode[1] in the manner hitherto described, and abdominal massage.[1] Satisfactory results have been obtained by these means, and greater attention to them, I feel certain, would not be misdirected.

A FEW THOUGHTS ON THE TECHNIQUE OF HYSTERECTOMY.[2]

BY JOSEPH EASTMAN, M.D.,

PRESIDENT, AND PROFESSOR OF DISEASES OF WOMEN AND ABDOMINAL SURGERY, CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS, INDIANAPOLIS.

THE frequent occurrence of pathological conditions demanding the removal of the uterus would seem to make "the technique of hysterectomy" of special interest at the present time. Since the publication of my paper in the *Indiana Medical Journal*, and its translation into German ("Memorabilien," *Zeitschrift für rationelle praktische Aerzte*, July, 1890), I have received letters from several distinguished members of the profession seeking more definite information in regard to my method of hysterectomy. This has induced me to present these few thoughts and report additional illustrative cases.

First, let us consider the operation by abdominal section for fibroma. The important question is as to the treatment of the pedicle. Treat it extraperitoneally? Yes. But shall that be in an abdominal or in a vaginal wound? In conversation with Dr. Bantock in his office in London, I learned that this distinguished advocate of fastening the pedicle in the lower angle of the wound had, like myself, found cases of multinodular fibroma in which the new-growths filled the pelvis, disorganizing broad ligaments and the uterine cervix to such an extent that no pedicle could be formed. He deals with these cases by enucleation, packing with gauze and draining through the abdominal wound, after having fastened the serous covering of the pelvis to the serous lining of the abdominal wall. There can be no cut-and-dried method applicable to every case. Each is a law unto itself. In the following three cases, as well as in those reported in the previous paper, no pedicle whatever could be formed which could be brought up and fixed in the lower angle of the wound. For this reason one of the cases had been rejected by a good operator. The suggestion to enucleate the fibrous nodules and then make a pedicle could not have been carried out in these cases, as the elastic ligature would have cut off the top of the vagina, or would not have been low enough to include healthy tissue be-

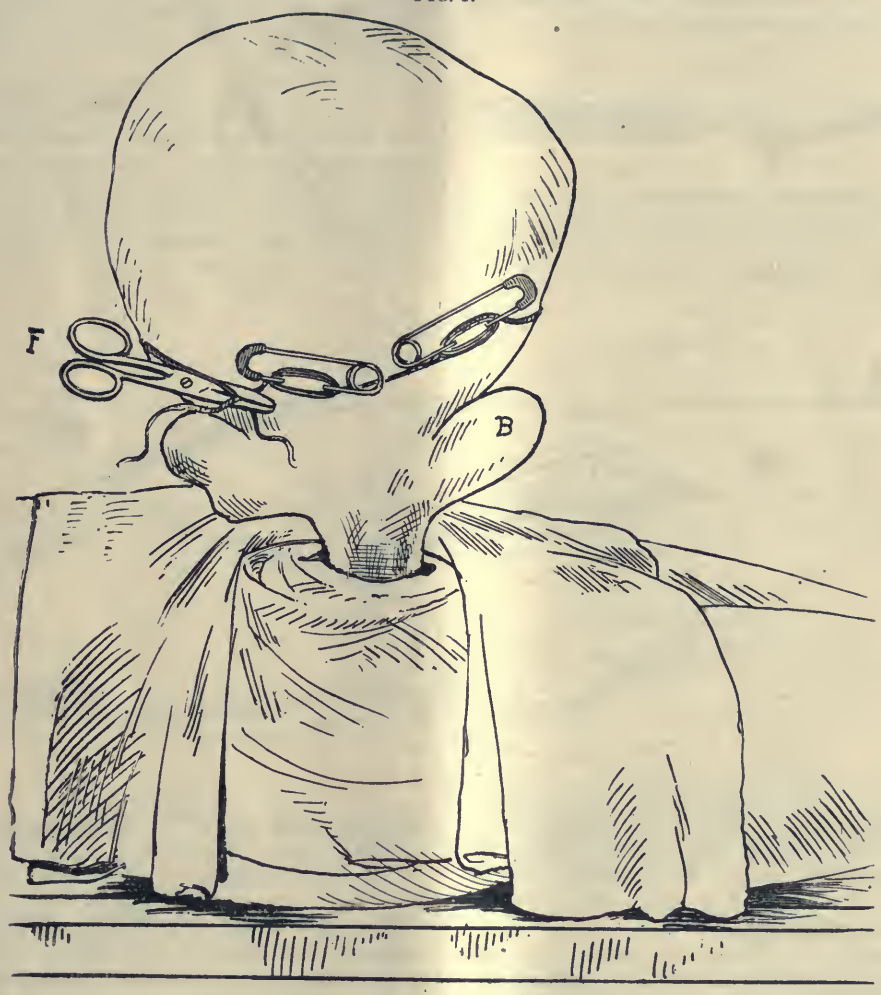
[1] The American Journal of the Medical Sciences, July, 1890.

[2] Based on an experience of 245 abdominal sections, 53 of which were hysterectomies. Read before the Gynecological Section of the American Medical Association, Washington, D.C., May 6, 1891.

low the cavities from which the fibrous nodules had been enucleated. To leave pockets without drainage would be bad surgery.

Case I.—Mrs. H., forty-five years old, was the mother of three children. She was referred to me by Dr. Evans, of Greencastle. Following an attack of la grippe, her health began to decline. When I saw her, four months later, the symptoms pointed to the existence of an abdominal tumor that filled the pelvis, extending up into the abdomen as high as the umbilicus. Celiotomy was performed May 8, 1890. The tumor was lifted forward, out of the abdomen. There were nodular masses, as large as the fist, well down in both broad ligaments, and one nodular mass, as large as a hen's egg, between the bladder and uterus. These nodular masses prevented my raising the tumor out of the pelvis. With an elastic ligature of rubber-tubing, kept from slipping up or down by pins at various places on the surface of the tumor, I encircled the tumor below the point where it was deemed best to sever it. (See Fig. 1.) The surface of the tumor was wrapped with the Esmarch bandage to diminish its circulation. Having been careful to apply the elastic ligature, the bulk of the tumor above the ligatures was then cut away so as to leave sufficient peritoneum to cover the enormous wound. I then opened the capsule of the tumor. Applying the forceps to arrest hemorrhage, I enucleated the nodular masses from beneath the ligature, which, contracting as I removed each mass, unpuckered the outer layers (mostly composed of hypertrophied uterine fibre) like a purse-string. My staff (Fig. 2) was then passed into the vagina to a position behind the cervix uteri and below the elastic ligature. Then, cutting upon the groove of the staff, I began ligating and cutting; as the staff had located the cervix I was enabled to extirpate it without interference with the ureters. A considerable portion of the anterior wall of the body of the uterus was left, as it was in such close contact with the bladder that its removal was deemed inadvisable. As the ovaries and tubes were much diseased, I tied them off. The ligatures, twenty-five in number, were left eight inches in length, and twisted

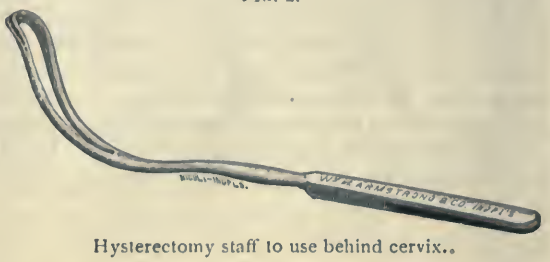
Fig. 1.



B, bladder. *F*, safety-pinning elastic ligature.

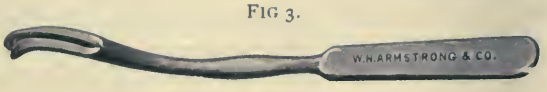
into one cord. A pair of forceps was then passed into the vagina, the ligatures grasped and drawn out of the vulva. A glass drainage-tube was then

FIG. 2.



Hysterectomy staff to use behind cervix..

FIG 3.



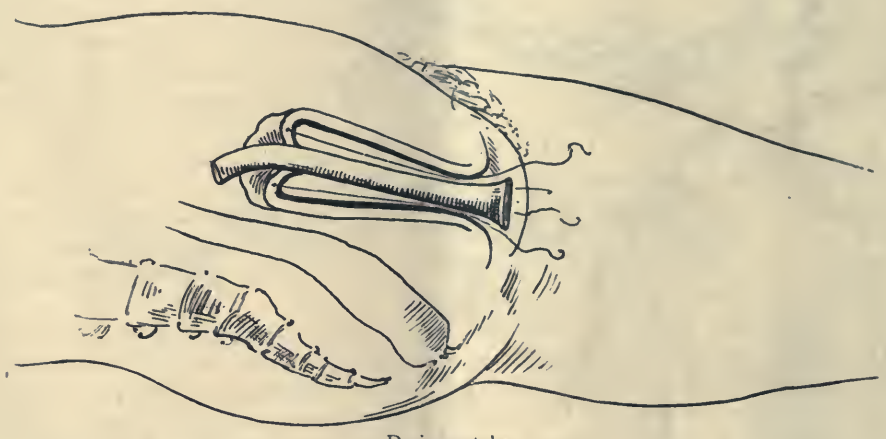
Staff to use at side of cervix.

passed per vaginam into the wound, and for three days frequently washed out to secure a perfect outflow of blood and serum. By traction on the long ligatures, which turned the raw edges into the vagina, the serous margins of the pelvic wound were brought together as closely as possible. The abdominal wound was closed at once. Recovery was complete and satisfactory.

CASE II.—Mrs. I., thirty-five years old, was referred to me by Dr. H. Jameson, of Indianapolis. When first examined she gave the following history: There had been loss of weight and strength for the past two years. She had had no marked hemorrhages. Physical examination revealed the pelvis completely filled by a hard, fibrous tumor so situated that the cervix uteri was with difficulty found, being high up behind the os pubis, and well to the right side. The tumor also occupied the abdominal cavity as high as the umbilicus. I used electricity for some three months, employing as strong constant currents as the patient could bear. The patient became disgusted with the treatment. Celiotomy was performed May 20, 1890. The abdomen having been opened, the tumor was encircled as in Case I. I then opened the capsule of the tumor, and enucleated from the posterior uterine wall a mass as large as an ordinary human head. Several bleeding-points in the capsule were caught with forceps. My staff was then passed into the vagina, held closely behind the cervix and cut upon. As the staff was withdrawn, I inserted my finger into the opening; then by ligating and cutting, the remaining portion of the uterus and capsule of the tumor were removed. The peritoneal margins of the wound were brought together; the ligatures, having been left long, were drawn out of the vulva and a glass drainage-tube inserted. The abdominal wound was closed. The patient made a good recovery.

CASE III.—Mrs. S., forty years old, was referred to me by Dr. Hodges, of Indianapolis. Examination revealed a large, multinodular mass filling the entire abdominal cavity, while one large subserous nodule extended high into the left hypochondriac region, displacing the spleen and left lung upward. Celiotomy was performed June 19, 1890. The abdomen was opened and the tumor brought forward and lifted out. I then proceeded as in the previous cases. The patient made an entirely satisfactory recovery, the highest temperature having been 100°, the highest pulse-rate 95.

FIG. 4.



Drainage-tube.

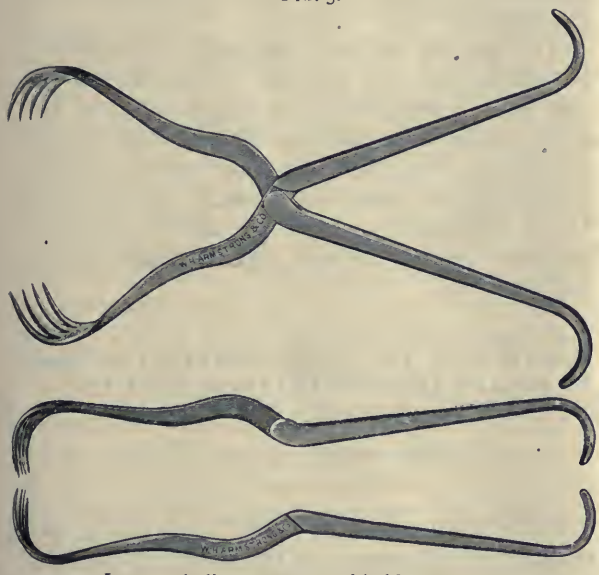
CASE IV.—Mrs. P., forty-nine years old, had suffered from uterine hemorrhage for thirteen years. I first saw her with Dr. G. W. Kemper, of Muncie, Ind., when I found and removed a sloughing fibroid mass that would have filled a quart bowl. The uterus seemed to contract, but could be distinctly felt between the umbilicus and the pubes. The hemorrhages did not return for six months; during this time she enjoyed good health. Soon after the return of the hemorrhages, another mass, as large as a goose-egg, was forced into the vagina and removed by Dr. Leavens, of Middletown, then her medical attendant. On my return from Europe, in October, I learned that the hemorrhages had not ceased, whereupon I removed the uterus as in the three previous cases. The mass removed was as

large as my doubled fists. The inner surface of the uterus was covered with bleeding, fungous growths; that, in the absence of a discharge of fibrous fragments and blood for thirteen years, would be strong clinical evidence of malignant degeneration. The patient made a good recovery. The second specimen[1] was removed by my method, with the recovery of the patient. Dr. Lovett, of Goodland, Ind., was her medical attendant.

In the last two cases, a pedicle could have been formed to fasten in the abdominal wound. Still, the women, in my opinion, were less mutilated and the abdominal wall being free, are in a more nearly normal condition, while I am sure that the period of convalescence was two weeks shorter than it would otherwise have been.

One of the greatest dangers to be avoided consists in the contamination of the peritoneum from the uterine cavity, especially when the latter is much enlarged and contains fluid. I use a large cautery

Fig. 5.



Large vulsella to extract and hold tumor steady.

to cut the surface of the stump and plunge the cautery freely down into the vagina. Another source of difficulty is constituted by the retraction and obliteration of the vaginal portion of the cervix, when the tumor is lifted out of the abdomen. I have, in two cases, been unable with my finger to find the cervix in the vagina. By passing the sound down the cervical canal I located the cervix to one side, where from other evidence it was least expected. I am still encouraged in my belief that, when the teaching shall have become obsolete that these tumors are comparatively free from danger and give little or no trouble after the menopause, we shall deal with the small tumors by removal of the uterine appendages, and with the larger ones by extirpation, and have as low a rate of mortality as we now have in removing ovarian tumors.

We cannot hope to reach this much-desired Mecca in our surgical pilgrimage if we stick to some buck-ram rule in operating and ignore the fact that the *peculiarities of tumor and pedicle* should determine our method of procedure.

Fortunate is he who can comprehend the anatomical and pathological bearings in a given case, and can *use good judgment* at every step of the operation *and in each and every emergency*.

Fig. 6.

Hook-needle.

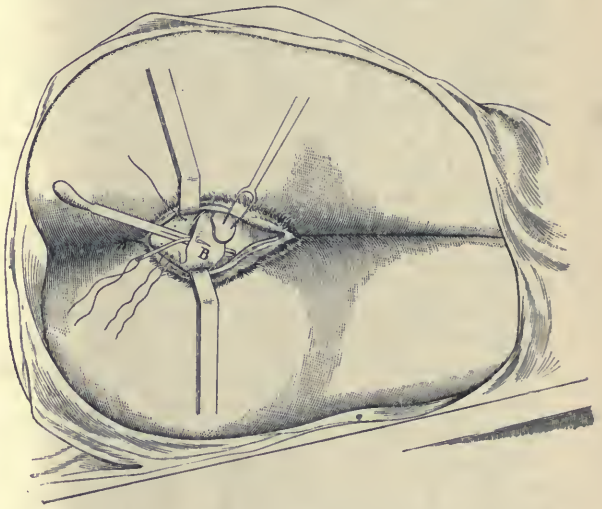
Vaginal Extirpation.—In my last twenty vaginal extirpations I have operated with the patient on the

Fig. 7.

Sound with grove on concave side.

side, using the position and speculum of the immortal Sims. I draw the uterus down very little.

Fig. 8.



I sometimes use ligatures alone, sometimes forceps, being governed by the circumstances in a given case. When ligatures are used, I first separate the uterus from the bladder and then open Douglas's pouch.

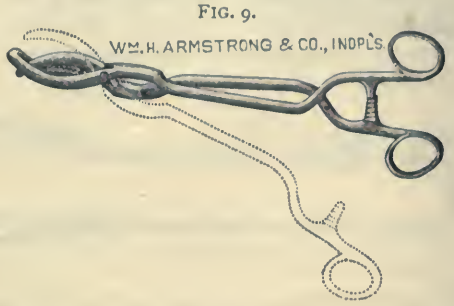
The hook-needle (Fig. 6), with the ligature, is then passed around the broad ligaments and the

[1] Specimens not shown, though present, as the discussion was cut off for want of time.

ligatures are tied. By the aid of this grooved sound (Fig. 7), the now constricted broad ligaments can be easily fixed and cut, three or four ligatures on each side being sufficient to secure the vessels. (See Fig. 8.) The ends of the ligatures are left long that they may assist in the drainage of each and every part of constricted tissue.

One advantage of the ligature is that an ovary or tube may be easily brought down and removed, no forceps obstructing the way.

FIG. 9.



Forceps.

When forceps (Fig. 9) are used, I proceed as follows: The uterus having been separated from the bladder, and Douglas's cul-de-sac having been opened, a strong ligature is passed around the ligaments by means of the "hook-needle" (cautiously avoiding the intestines); this ligature being tied, the ligaments are constricted to a round mass. The operator than passes the index finger of one hand behind the uterus, when the assistant easily slides these forceps, guided by the operator's fingers, around the ligaments and locks them. The same procedure is repeated on the opposite side and the ligaments severed, leaving the forceps to be tied together, side by side, as one forceps. The advantages claimed, are: (1) that by narrowing the ligaments their stumps are brought down into the vagina, so that the peritoneal cavity can be closed above the forceps; (2) the stumps of the broad ligaments are not left within the peritoneal cavity to discharge septic material as soon as the forceps are removed—a result that must always follow in any case in which the pressure of the forceps does not narrow the ligaments before compressing them; (3) only two forceps are used; (4) when the patient is weak, the operation can be quickly done; (5) the screw can be taken from the forceps and the blades applied separately and locked afterward, with no danger of hemorrhage, when they have been left forty-eight hours.

Whether ligatures or forceps are used the *stump must be treated extra-peritoneally*. The serous margins of the wound must be brought nicely together between the two pedicles. The utmost care in cleansing the pelvis and adjusting the parts is as necessary here as after abdominal section. A small drainage-tube may be used if necessary. It is astonishing to me that the results have been as good as they have, when putrid fragments from the pinch of many forceps have been left to contaminate the peritoneal surface of the pelvis and intestines. When the technique shall have been perfected, the mortality will be lowered and the field for the operation surely widened. We had better occasionally remove a uterus not yet cancerous, when the organ is rendering the patient an invalid, than wait until the perimetrium is involved. Again, there are many women with complete prolapsus, wearing supports and working for the support of themselves and families; women with retroverted uteri, complicated with prolapsed and adherent ovaries; women with hystero-neuroses, approaching a lingering menopause, with a history of insanity in their families—morphine-poisoned, nerve-wrecked, brain-shattered, reason-dethroned, asylum-homed—to whom a vaginal extirpation of the uterus, without regard as to whether or not the uterus be cancerous, would come as a blessing.

The primary mortality attending hysterectomy for cancer can and must be lowered, to the end that women will accept the operation earlier and thereby obtain the best guarantee against return of the disease. The better secondary results obtained in removing the cancerous breast by the method of Dr. S. W. Gross must teach us that the question is not how quickly can the operation be done, but how perfectly.

REMARKS ON THE DISTURBANCES THAT MAY FOLLOW INSTRUMENTATION UPON THE MALE URETHRA AND BLADDER.

BY PAUL THORNDIKE, M.D.,
OF BOSTON.

FOR nearly one hundred years it has been a well-recognized fact that a certain degree of constitutional disturbance is apt to follow the introduction of an instrument into the male urethra. This disturbance, varying as it does in intensity, and manifesting itself by different sets of symptoms in different cases, has received a variety of different names, and has been the subject of much speculation and of a great deal of painstaking investigation. Under the names catheter chill, catheter fever, urethral fever, and urinary fever, various conditions have been described, various classifications of these conditions have been made, and various ideas as to the causation of the disturbance have been advanced. In this way there has naturally arisen considerable confusion as to what clinical condition is meant when one or the other of these various terms is employed.

It has seemed to the writer that this confusion was

largely a verbal one, and that the conclusions reached by various observers in reality agreed very well. It is the object of these notes merely to make a simple classification of the different conditions as they exist clinically, and to speak briefly of each one. Looking at the matter purely from its clinical aspect, we find that all cases can readily be grouped under a few headings.

I. *Cases of "Shock."*—We are all familiar with the condition that is commonly spoken of as "catheter chill." After instrumentation upon urethra or bladder, especially if it be the patient's first experience of the sort, he becomes faint, and may completely lose consciousness, or he is seized with one or more short rigors. This attack is accompanied by little or no fever, passes off in a few moments, and, as a rule, is followed by no bad result of any kind. The attack comes directly or very shortly after the passage of the instrument, is of short duration, and is followed by little, if any, constitutional distubance. The attack is also more likely to occur and to occur with greater violence the deeper into the urethra the instrument is passed.

Of this form of disturbance but little need be said. It is clearly a case of nervous shock occurring in a healthy person; that is to say, the rigor is a physiological one, occasioned by the local irritation of the instrument, and following more or less immediately upon its passage. The attack may take the form of a fainting-spell or of a chill, but it is not followed by any symptom or group of symptoms indicating septic infection. It is the simplest form of shock following mechanical irritation of the urethra or bladder.

There is, however, a severer form of shock that is fortunately much rarer. Mr. Banks, in an admirable article in the *Edinburgh Medical Journal* for 1871, reports several such cases, and, among others, the following, which will serve as a type of this class of cases:

"A man between forty and fifty years of age was admitted to the Liverpool Royal Infirmary for urethral obstruction. A false passage was found, but a catheter (6–7 English) was, without any undue violence, passed into the bladder. There was very little pain, no bleeding, and nothing to indicate any lesion of the urethra other than the preëxisting false passage. Almost immediately after the entrance of the catheter into the bladder, the patient was seized with a severe rigor. The instrument was cautiously withdrawn, but the patient became profoundly collapsed and died in a few moments. In this case no autopsy was allowed, but there are recorded many such cases in which the autopsy showed no lesion to account for the fatal issue. More or less advanced renal disease is, however, often found at the autopsy in these cases. This, then, is an example of the severest form of urethral shock."

In different cases there may be various other symptoms, *e. g.*, vomiting, diarrhea, retention or suppression of urine, associated with the collapse, but they are all cases of this type; that is, they are all sharp attacks coming on immediately or very shortly after instrumentation, and the fatal result occurs rarely later than forty-eight hours from the beginning of the attack. There may be little or no fever, and the attack begins so soon after its cause that there has been no time for any septic absorption to have taken place.

Again, in those cases in which there has been suppression of urine, death takes place so quickly that it cannot by any possibility be attributed to uremia following the suppression. These are cases of shock, pure and simple.

II. *Cases of Acute Fever.*—We come next to a class of cases having little or nothing to do with the class already spoken of, and yet concerning the nature of which the greatest differences of opinion exist. I mean the acute febrile cases—the commonest form of urinary fever, and the type of case that we see most frequently and often speak of as a case of "catheter fever."

That these cases may have certain symptoms in common with the class of cases already mentioned is certainly true, and it is apparently for this reason that some writers have called them cases of shock; others, cases due to uremia; while still others mention malaria as the causative element. A typical case of this class would be the following:

A patient in good general condition is examined for stricture, and a bougie or steel sound passed with little or no difficulty. After several hours, and generally shortly after the first urination following the passage of the instrument, the patient experiences a distinct chill. He looks ill, has an anxious expression, and begins to complain of pains in back and head. The temperature rises, and there may be vomiting and retention of urine. The temperature goes higher, and thirst becomes marked. This febrile attack lasts a few hours, and gives way to a period of sweating, after which the patient is left in an exhausted condition. As a rule the fever subsides within twenty-four hours, and on the next day he has well-nigh recovered his ordinary health. This usually ends the trouble, but the attack may be repeated once or oftener without fresh provocation of any sort. This recurrence, with no further instrumentation or other assignable cause, would, of course, suggest further trouble of a serious nature, but attacks of this sort may go on for some weeks, with many recurrences, and yet end in recovery. Sir Henry Thompson, in speaking of these recurrences, says: "And sometimes the reason for the

recurrence is not very obvious; thus, if no cystitis appears, or if a preëxisting slight attack is not intensified, suspicion may arise as to the presence of inflammation in the ureter or pelvis of the kidney of either side, to be sought for by examination for local tenderness, etc. And when there is no such affection, and no renal implication or other cause—septicemic infection for example—discoverable, the recurring attacks will probably soon diminish and disappear." Can such an acute febrile attack be caused by nervous shock? If so, the attack should follow immediately upon its cause, and should be the greater in proportion as its cause is the more severe and prolonged. This is not the case, for the fever does not occur until several hours after the instrumentation, and more commonly a short time (from one to four hours) after the first micturition following the use of the instrument. It is also quite apt to follow a simple, easily performed catheterization. Then, too, if due to shock, we should not expect any prophylactic after-treatment to prevent the attacks after urethral operations. Yet it would seem that nearly all the cases escape with no disturbance whatever, when, after internal urethrotomy, for example, steps are taken to prevent contact of urine with the wound. It is also well known to surgeons that these attacks are comparatively rare after an external perineal urethrotomy or lithotomy when proper bladder-drainage is secured. It is also found that the position of the wound in operations upon the urethra has a direct influence upon the appearance of these symptoms.

Mr. Reginald Harrison says: "We find such symptoms more frequently follow when the wound is made on the floor of the urethra in preference to the roof. A dependent position of the wound is more likely to be associated with the fever than one not so situated."

Mr. Harrison adopted the theory that these febrile attacks after urethral operations were due to poisonous material of some sort furnished by the urine, and absorbed through the wound made by the operation. He performed a number of operations with the idea of keeping the urethral wound entirely free from contact with urine, either fresh or decomposed. To accomplish this end he performed an internal urethrotomy on each one of a series of cases of anterior stricture, and then secured absolute and perfect drainage in each case by also performing an external perineal urethrotomy. In this way the urethral wounds were kept free from all contact with urine, and in no such case was there any sign of urinary fever, while in the internal urethrotomies that he had previously performed rigors and febrile symptoms were of common occurrence.

Other observers do not agree with Mr. Harrison on this point. Dr. F. S. Watson, of Boston, has recently performed a series of such operations, *i. e.*, combined internal and external (perineal) urethrotomy; and in two of the cases with perfect bladder-drainage and with every care given to surgical cleanliness there were attacks of urinary fever. Mr. Harrison, then, is a supporter of the absorption theory of the causation of this fever, and in his articles on the subject tries to answer the two main arguments that are brought forward against this view.

In the first place it is asked: "If this fever is septic, why do we not have it in very severe form in cases of urinary extravasation?" His reply to this is, that when urine is extravasated it acts as a local poison, killing the surrounding tissues, so that little if any absorption takes place.

Again it is asked: "If this fever is septic, how are the rapidly fatal cases to be explained—that is, the cases that die in from twenty-four to forty-eight hours, with no lesion of continuity in urethra or bladder discoverable at the autopsy?" To begin with, such a lesion may readily exist, and be an ample channel for absorption, and yet not be readily found at an autopsy; and beside this, the cases referred to are not cases of urethral or urinary fever at all, but are admirable examples of the severer form of shock already spoken of at some length.

Now comes the question: "If this fever is due to the absorption of certain poisonous products, what are these products? In a series of articles that appeared in the French medical journals between 1882–86, Dr. Bouchard reports the results of an interesting series of investigations in this direction. Bouchard found that in the healthy person there exist certain alkaloids that are formed in the intestinal tract as a result of the activity of putrefactive organisms; that these alkaloids are excreted in part by the kidneys, and so are to be found in normal urine; and that the diseases that augment the production of these intestinal alkaloids must also augment their presence in the urine. Then he found that urine injected subcutaneously produced certain effects upon rabbits, and that these effects varied accordingly as the person furnishing the urine was healthy or not. Next he proved that the symptoms produced were not due to any of the ordinary chemical constituents of the urine, and inferred that the alkaloids mentioned were therefore the causative agents. At all events, whether the poison absorbed consists of bacteria themselves or of the results of bacterial activity, these investigations are extremely valuable, if only as a suggestion of how much there remains for the medical chemistry of the future to make clear to us.

III. *Cases of Chronic Fever.*—We now reach a third class of disturbances following urethral instrumentation. These are the *chronic* febrile cases, which

form a very distinct class by themselves. In them the attack follows the passage of a catheter for the relief of a more or less distended and atonied bladder. An old stricture or a gradually progressive prostatic hypertrophy has caused a long-standing obstruction to urinary outflow; the result has been the retention in the bladder of a slowly but constantly increasing quantity of urine—so-called "residual urine"—and a consequent long-continued distention and slowly increasing atony of that organ. Such a case comes sooner or later to the surgeon for relief, the patient complaining that he cannot hold his water; that it is constantly dribbling away from him.

Inquiry reveals the fact that the trouble has existed and has been increasing for several years, and the catheter draws off a considerable quantity of residual urine. The patient is instructed as to his condition, and is regularly started on his catheter-life. In a few days he begins to feel poorly, has chilly feelings, but not necessarily a distinct rigor. He becomes feverish, but his fever is slight and has distinct intermissions. He loses his appetite, suffers considerably from thirst, and feels wretched at all times; his tongue becomes dry, and covered with a brown coating. Examination of the urine generally shows a cystitis more or less marked, even if this condition did not exist before the beginning of regular catheterism. This condition may persist for weeks, and yet, with proper care, the patient recover, or it may terminate fatally, in which case there will almost invariably be found advanced disease of ureters and kidneys.

If the obstruction has been of long duration before relief was sought, there is usually a more or less marked atony of the bladder-wall and a urine of very low specific gravity, the latter suggesting the probable existence of dilated ureters with hydro-nephrosis or pyo-nephrosis. These are the cases that terminate fatally. If, on the other hand, relief was sought early, the febrile disturbance will probably disappear gradually, and the patient may continue his catheter-life in comfort for years. Sir Henry Thompson says that when catheter treatment is begun so early that the quantity of residual urine in the bladder does not exceed ℥xii-xv, a favorable prognosis may generally be given. It has been asserted, notably by Sir Andrew Clark, in an article published in the London *Lancet* for December 22, 1883, that this form of fever may exist and prove fatal, with no such serious disease of the kidney discoverable at the autopsy. If this is true, it must occur rarely, since it is certain that in most of the cases such disease exists. He mentions two cases that died of this form of fever. In one there was no autopsy, and in the other the report is as follows: "The prostate was enlarged, the bladder was dilated and thickened —viewed from the inside it was trabecular and slightly saccular—the mucous lining congested and in part *eroded*, and everywhere coated with a grayish-white, stinking mucus. There was nothing to be detected in the ureters or kidneys, although they were carefully examined. With such a vesical condition as this, is it not possible that the fatal issue was due to a septicemia that had its starting-point in the bladder? What is the cause of such an outbreak of fever? Mr. Henry Morris explains it as follows. He says: "It is to the state of the kidney prior to surgical treatment, and not to the state of the bladder after the commencement of catheterism, that we ought to look for an explanation of this form of fever." In other words, this so-called "surgical kidney" is not necessarily the result of an extension upward of a septic inflammation from below, but the disease already existing in the kidney is the starting-point of the trouble that follows catheterization. He says that two conditions are essential to bring about the disturbance:

First. A preëxisting degeneration of the secreting substance of the kidney.

Second. An alteration in the intra-renal pressure as a result of obstruction, whereby the ureters, pelves and calices of the kidneys become dilated.

When under these conditions a catheter is passed, a state of active congestion is initiated in the kidneys by the release of this pressure. This increased blood-supply to the kidneys cannot be controlled by the natural elasticity of these organs and their capsules, because the preëxisting chronic changes in these organs have led to a firm adhesion of the overstretched capsules; and the elasticity of the renal substance has been destroyed by the intra-renal pressure of the long-pent-up urine; so that in the condition of active congestion the kidney-substance is between two firm pressures, and the result is an acute pyelo-nephritis, in addition to the chronic interstitial changes that already existed in the kidneys. So far as I am aware, no explanation has been offered for the fatal results that are said to occasionally take place without the existence of renal disease to account for them.

IV. *Cases of Direct Septic Infection.*—Before speaking of the treatment of these various forms of disturbance, it seems proper to mention the trouble that may arise as a result of direct septic infection following instrumentation upon urethra or bladder.

Of this but little need be said. As the result of the passage of an unclean instrument we may get a simple cystitis, accompanied by slight, if any, constitutional disturbance. This may, and generally does, clear up and disappear under proper treatment; or, the septic process may extend up the ureter and cause a pyelo-nephritis and death from the so-called surgical kidney.

Again, we may have absorption of the septic

material through a wound made by the instrument, and so a true septicemia may begin. This may prove slight and end in recovery, or may speedily prove fatal. Finally, as a result of purulent absorption we may have the rare complication of pyemia with pus-formation in joints, pleuræ, etc. This proves fatal in the majority of cases.

We have spoken of four classes of disturbance following instrumentation on the male bladder and urethra, and in these four classes can, I believe, be arranged all cases of disturbance of this sort. These were:

First: The cases of "urethral shock" brought about by the simple passage of an instrument in the urethra; very common, and, as a rule, of little importance, but occasionally terminating in speedy death. This fatal form is rare, and generally associated with renal disease of some sort.

Second: The cases of "acute urinary fever," probably caused by absorption of poisonous products from the urine; these acute attacks at times recur without any known cause, such as further instrumentation.

Third: The cases of "chronic urinary fever," coming on after catheterism in cases in which for a long time obstructive disease in some form had preexisted.

Fourth: Cases of "septic infection" from an unclean instrument. This may be merely a mild cystitis, may extend upward and cause septic trouble in the kidney, or may manifest itself as a true general septicemia or pyemia.

It is certainly unwise to use any one term—be it "catheter fever" or some other—to include these different sets of cases. The cases of nervous disturbance, the "shock" cases, differ in no respect from cases of nervous shock produced in other ways. The same may be said of the septic cases. This leaves us two sets of cases to which the term "urinary fever" may properly be applied: the acute cases, and the chronic cases occurring in patients with obstructive disease. To these two classes the terms "acute urinary fever" and "chronic urinary fever" may be properly applied.

Treatment.—Of the treatment of acute urinary fever there is little to say. Quinine, of which much has been written, is of no value in preventing the attacks. This, however, cannot be said of aconite; which in two-minim doses of Fleming's tincture, as recommended by Mr. Long, seems often to be of value as a prophylactic. Frequent, small doses of digitalis are of value in cases associated with suppression of urine. Dr. Keyes, in speaking of prophylaxis, says: "I do not know of any remedy that can in all cases avert chill, but I place more reliance upon a combination of pilocarpine and morphine than on anything else."

The importance of surgical cleanliness and proper drainage of urine in the treatment of urethral and bladder cases cannot be over-estimated. All instruments should be surgically clean, and in cases of urethral operations, when it is not deemed best entirely to prevent contact of urine with the wound, either by tying in a catheter or by doing a perineal section, the urethra should be cleansed by frequent careful irrigations.

That by proper care the development of chronic cases can always be prevented is, of course, not true, but it is true that the frequency of their occurrence can be controlled by careful attention to the details of catheterism.

Having decided to start our patient on his catheter-life, how are we to proceed? The patient should rest quietly indoors, upon a light diet (chiefly milk) for two or three days before the first catheterization, and for the first week or so of regular catheterism. The catheter should be passed regularly, as often as may be found necessary in the individual case, and with the instrument that is found best adapted to that case (generally a Condé instrument of moderate size). The bladder should never be completely emptied, and this is of greater importance the longer the obstruction to natural urination has existed and the greater the quantity of residual urine and atony of the bladder-wall that results. A good method to pursue is to slowly draw off a moderate quantity of urine, and then to replace this by a smaller quantity of some mild antiseptic solution, such as boric acid, permanganate of potash, or corrosive sublimate. In this way the bladder can, in the course of a few days, be carefully and gradually emptied without any sudden diminution in the pressure of the pent-up urine that has so long been present.

There should be no unnecessary manipulations in the early days of the catheterism, and irrigations of the bladder for the cure of a purulent cystitis should be deferred until the patient's bladder has become accustomed to its new condition. Finally, after he has become a little familiar with the procedure, the patient may be instructed to catheterize himself. If, in cases of this sort, some such plan were carefully carried out, we would have fewer and milder cases of chronic urinary fever.

SOME SUGGESTIONS AS TO THE NATURE AND CAUSATION OF ECZEMA.

By WOODS HUTCHINSON, M.D.,
of Des Moines, Iowa.

It would be a well-nigh hopeless endeavor to attempt to say anything fresh about eczema, since one might about as well attempt originality in discussing the contents of Scarpa's triangle, or to add another zygapophysis to the dorsal vertebræ. Gallons of ink have been spread upon acres of paper in the description of its chamelion-like variations, and the discussion of its relation to age, sex, diet, clothing, and the stages of the moon, would fill volumes. The list of substances recommended in its treatment is almost co-extensive with the pharmacopœia; in fact, the drug that is not suspected of being useful in this connection is apparently yet to be discovered. The very voluminousness of its literature, however, is proof both of the interest of the subject and the delightful uncertainty that surrounds some of its important relations; it may even serve as an excuse for presenting the following brief suggestions:

Rating it by the frequency of its occurrence, eczema certainly is entitled to a considerable share of the literature of disease, for it has probably one of the widest known ranges, both racial, personal, and geographic, of all pathological processes, attacking old and young, rich and poor, vigorous and feeble, with an impartiality that is positively refreshing by comparison with the strong tendency displayed by most other diseases to hit a man only when he is down. Jamieson estimates that it makes up or enters into one-half of all skin affections, while such is its infinite variability that Bulkley has found no less than one hundred and fifty different Latin terms applied to describe its changing moods. A disease of marked individuality, and yet having no single symptom that is absolutely diagnostic, and no microscopic appearance that can be called characteristic, it occupies in nosology a unique position. It is not my purpose to discuss this interesting process as a whole, but merely to submit for discussion two conclusions in regard to its nature and causation, with reasons that seem to me to support them.

These are, first, that eczema is merely the simplest, most rudimentary form of chronic inflammation of which the cutaneous tissues are capable, their easiest mode of expressing resentment at outside interference, the "retort direct," or "you're another," of their never-ceasing dispute with their environment. In other words, that the uniformity of the disease-process in different subjects is due to the similarity in structure and reactions of the tissues wherein it occurs.

Second, that the variations of the process are due principally to the infinite variety of causes that may excite it, and that in the great majority of cases are influences external to the body. Of course, I am aware that part of these conclusions would be accepted by nearly all dermatologists, part vigorously disputed, and part generally rejected, and that there is little new or original about them except their form, so that, to save time, I shall dispense with the quotation of authorities, and proceed to submit the considerations that seem to justify them, leaving the reader to decide upon their validity. First, and most important of all, is the fact that the pathological changes of eczema, whether microscopic or clinical, are in no essential respect different from those of a simple inflammation (dermatitis), except in the time required for their production and the modifications incident upon their more gradual development. An eczema differs from a burn in the same way that the decay of a prostrate monarch of the forest in its native glade differs from the blazing and crackling of a log upon the hearth. It is the time-relations that differ, the processes and their products being otherwise identical. A sunburn or scald reaches at one bound the erythematous or vesicular condition for the attainment of which in an eczematous fashion the repeated application of less active irritants for days or weeks would be necessary—except, of course, that the more rapid process produces less stable results, and the sudden change of tension in the nerve fibrils gives us pain in the place of itching. The stages and forms of eczema depend principally upon the degree or length of persistence of the irritation. Should the irritant be a feeble one, or but recently applied, we find only a general hyperemia and swelling of the epidermal tissues, with a sensation of heat or slight itchiness—the erythematous stage or form. Let the irritation be a little more vigorous or prolonged, and minute disseminated foci of exudation spring up all over the rete mucosum, and the papular stage is developed; another turn of the screw and each papule becomes rapidly swollen with serum, and bulging in the direction of least resistance, pushes up the epidermis, and forms a vesicle (eczema vesiculosum) that possibly ruptures (eczema madidans). Let the pressure rise a little higher, or the resisting power of the tissues be diminished, and there ensues rapid death of the cellular elements in the vesicles, the

pustular form, with its resulting crusts. At any stage of the game, on the withdrawal of the exciting cause, the hyperemia may disappear, the papules may shrink up, the vesicles dry down into scales, or the pustules into crusts, and a new term is needed —"squamosa" or "sicca." On the other hand, should the disturbing influence persist so as to keep the skin in a state of continual ebullition, the whole thickness of the corium becomes involved and thickened, nutrition of the superficial layers is interfered with, cracks form, the epiderm becomes horny or discolored, and "eczema chronica" is in possession of the field.

The second basis of my conclusion is, that a genuine and characteristic eczema can be produced upon perfectly healthy skins solely by the application of external irritants—in fact, a large and influential body of authorities declare that all eczemas are so caused. A familiar instance is the eruption following the exposure to "poison ivy," an eczema of the eczemas, with every characteristic symptom in perfection. It is hardly necessary for me to refer to the whole classes of "intertrigos," occupation-eczemas and clothing-eczemas, as further illustrations. The third consideration of interest in this connection is the fact that eczema is not limited to the human skin, but that the epidermis of all the domestic animals and of some plants is capable of an identical or analogous reaction. It would, indeed, seem to be one of the common inheritances of all living surface tissue. Its earliest analogue is, probably, the exudation of gummy or resinous fluids upon the stems or leaves of certain plants and trees, for the healing of wounds as a protection against fungi, or for the entanglement of insect enemies, and, in this connection, I can hardly resist placing the remarkable pouring or flowing out of the protoplasm from the surface of an amœba, by which it surrounds and encloses foreign bodies, and, if available, digests them. If these analogies be admitted, they would give to eczema a rational standing-ground as a reversion to a mode of action that was normal and useful to our remote ancestors—a relation that I believe, in the near future, will be traced in most of our distinctive disease processes; it seems, in fact, almost safe to assume it already in gout, cancer, and tubercle. Higher up in the plant scale we find a disease (the details of which, together with other interesting information, have been most kindly furnished me by Professor Pammel, of the State Agricultural College) that I am almost tempted to claim as a vegetable eczema, in "apple scab," caused by a fungus, *fusicladium dendriticum*. The presence of this parasite upon the bark provokes an exudation of cellular material from the cambium layer ("papular stage") that goes on to the formation of a layer or patches of cork ("horny stage"), and thus the softer tissues are protected from its ravages. In potato scab we have another similar process. Another fungus, *ozonium aunieconum*, produces a knotty eruption on the roots of the cotton-plant.

In domestic animals the eczemas are quite common, although perhaps not so frequent as upon the bare skins of the genus humanum. "Mange" in dogs, "grease" in horses, and "foot-and-mouth-disease" in cattle, are among the most familiar forms of its occurrence. I am informed by my friend Dr. A. B. Morse, D.V.S., that the morbid process is practically identical with that in the human subject, except that the pustular stage is more commonly and readily developed (as of course is the case in the hair-covered portions of the human epidermis), and that the best modern authorities regard almost every form of it as due to some germ or parasite—in other words, to almost the only chronic irritant from which the animal skin is not protected. Partial exceptions to this rule are the vesicular eruptions that often constitute the first stage of "collar-galls," or "saddle-galls," in horses, and that appear on the ears of dogs when chained up during summer-time. These are friction eczemas, due in one case to the pressure of the harness, and in the other to the combined influence of flies and scratching.

The fourth consideration bearing upon the inflammatory nature of eczema is the number of other diseases in which it constitutes the bulk of the morbid process. Scabies is but an eczema produced by the presence of the acarus or the sulphur applied to kill it, plus the actual burrows of the insect and scratch-marks. Pediculosis or phthiriasis is constructed on the same plan, and the seborrheas are probably at bottom eczemas. I think we would be justified in declaring that the pathological changes in the great group of trichophytoses or ringworms are eczematous, as the term "eczema marginatum" so generally applied to tinea cruris implies. In fact, the easiest form of dermic revolt against the tyranny of any parasite would seem to be an eczema.

Another straw pointing in this direction is the marked extent to which eczema prevails during infancy and childhood, when the poor little pink epiderm is struggling to adjust itself to the trying change from the nicely warmed water-bath in which it has been floating, to the flannels, soaps and changes of temperature and moisture of an unfriendly world. The innumerable caravan of "red gums," "prickly heats," "teething rashes," "heat rashes," "lichen scrofulosorum," etc., are all of this nature, and Bulkley, in his paper before the Berlin International Congress, gives tables showing that nearly 20 per cent. of all cases of eczema occur during the first five years of life, which is probably decidedly under the actual mark, so many cases at

this age being too slight to be considered worth treating.

If eczema be simply a dermatitis we can readily understand its well-marked preference for flexor surfaces, and especially flexures, as not only is the skin in these situations thinner, more delicate, and hence more easily injured, but, from the formation of the parts, perspiration, dust and foreign matter are much more apt to accumulate there, to say nothing of the mutual heat, friction or pressure of the opposing surfaces.

The so-called internal or predisposing causes of eczema seem, so far as our knowledge of this somewhat mysterious subject goes, to fall into line with the hypothesis. I think they can nearly all be divided into two main classes—those diseases or diatheses that throw too much vicarious excretory work upon the skin, or fill its vast mesh of bloodvessels with blood loaded with irritating nitrogenous substances—such as rheumatism, lithemia, diabetes and disturbances of the metabolic functions generally; and those states or influences that depress the resisting power of the skin and all the tissues of the body—such as exhausting disease, chlorosis, lactation, over-work or over-confinement, thus rendering it more vulnerable to external attacks. The first class, and it is by far the larger, is apparently simple, a case of response to local irritation from within instead of from without, although the addition of the latter is probably necessary to provoke an actual outbreak. Roughly speaking, the second class would seem to obey the general law that all morbid action may be initiated either by increasing the external pressure of the environment, or by diminishing the internal resistance of the organism. Of course, this explanatory suggestion is very crude, and only applies to very few of the difficulties of this vast and misty field, but so far as it goes it seems not wholly irrelevant.

If the probability of my first general conclusion is admitted, that of my second, that the variations of the disease are due to the variations of the cause, is practically implied, for if the essential morbid process be a simple primitive inflammatory change, it will then be modified according to locality, intensity and duration, all of which are determined by the nature of the influence that produces and perpetuates it. The chief value of this principle is as a basis of classification, and it seems to me that if on these lines we can succeed, ever so loosely, in dividing the mighty hosts of eczema, the classification will at least have the merits of simplicity, clearness, naturalness and practical working value. The mere location of a given case carries with it its prognosis and indications for treatment. With your permission I will submit a rough outline of such a classification, with a few illustrative cases. By far the most important is:

Class 1. Eczemas produced by influences entirely external to the body: divided into (a) climatic; (b) chemical; (c) mechanical or "frictional;" and (d) mycotic or parasitic.

Class 2. Eczemas produced by bodily influences or properties acting from without; examples, "intertrigo," eczema of the anus, the groin, or the back of the ear.

Class 3. Eczemas produced by bodily influences acting from within: (a) locally, as gout or rheumatism; (b) generally, as lactation, or anemia.

It must be admitted that not even these rough divisions are based upon absolutely hard and fast lines. Not only will Class 1 contain nearly 80 per cent. of all cases, but its method of causation will in some degree be present in nearly all those falling in the other two classes—indeed, it is hardly possible to conceive of an eczema occurring without some external provoking cause, although there are many cases wherein it is so palpably merely the last straw, the feather's touch, that precipitates the explosion, that we are justified in ascribing them to the preëxisting and predisposing conditions of the tissues. On the other hand, there are cases to which the classification will hardly apply, since the most careful investigation will fail to discover any cause whatever for them. It is a significant fact, however, that idiopathic eczema is becoming an extinct species almost as rapidly as is functional disease of the nervous tissues.

I will now briefly present a few typical cases that will illustrate my general drift better than pages of explanation. As an example of the first division of Class 1, climatic eczema, we have:

Case I.—A gentleman of about forty-six years of age, who ten years previously had emigrated to Iowa from the North of England. Within a few months after his arrival he began to be annoyed by acute attacks of vesicular eczema, starting upon the lower eyelids and spreading to the cheeks, eyebrows, and even to the folds of the neck and jaw; it also occasionally appeared between the fingers and on the backs of the hands. These attacks nearly always appeared to follow some unusual exposure to sun or wind, and would last from three to six days, and from the itching, burning and swelling of the parts caused great discomfort. He was in perfect health, and had never suffered from any similar affection in England. No treatment seemed to have any appreciable effect except the use of tar-water, which, freely applied, promptly relieved the itching, and caused the eruption to subside in a few days, only, however, to reappear on the next exposure. After three years' residence here he returned to England for a short visit, when, to his great relief, the trouble left him at once, and did not reappear until after his return to Iowa. From

this time the affection seemed gradually to subside, and in two or three years almost ceased to trouble him, reappearing only in a mild form after any unusual exposure to sun or wind.

CASE II.—A healthy young girl, about eighteen years of age, complained of an eruption that appeared upon the backs of her hands and wrists whenever they were especially exposed to the sun or wind, as in boating or fishing. The eruption annoyed her greatly by the itching and burning that accompanied it, although lasting only a few hours after the cessation of the exposure. It consisted of a large number of scattered papules, elevated and of bright-red color, that gave the whole skin a distinctly roughened and shotty feeling to the touch.

CASE III.—A college student, about twenty years of age, called my attention to an irritable condition of the skin of his nose that had appeared, he stated, since he left his home in Florida three weeks before. On examination I discovered upon the sides of the nose and cheeks a small "butterfly patch," of minutely vesicular, elevated scaly eruption, which itched and burned slightly. On questioning him he recollected that he had been similarly troubled on visiting in the North on two previous occasions. He had never thought of a climatic origin. I simply advised a little care as to soap, washing, etc., and in the course of a few months the eruption ceased to annoy him, and has now almost entirely disappeared.

Cases of eczema due to chemical causes, or "poisonings" of various kinds, are so common and so well understood that the division needs no illustration. For the same reason, in this brief sketch, a single case under the third or mechanical division must suffice:

CASE IV.—A healthy young merchant, of about twenty-five years of age, replying to the usual question in an examination for life-insurance, said he had no "eruption on the skin," except a "spot" on his right leg. On inspection I found this to be a small, elevated, roughened patch of scaly eczema, about the size of a nickel, just over the shin-bone, about three inches below the knee. He said it had been there some months, and occasionally itched. I was quite at a loss to account for its singular position and shape until I found that it was exactly at the spot where the clasp of a somewhat elaborate hose-suspender rested upon the skin. There was no similar eruption upon any other part of the body, and the surrounding skin was perfectly healthy.

Under the mycotic division I have to report:

CASE V.—A boy, of about nineteen years of age, complained of "spots on his skin." The whole surface of his body was dotted over with round or oval patches of elevated scaly eruptions, of a yellowish color, varying from one-half inch to one inch in diameter. He stated that these had appeared about one month before upon his chest, and gradually spread. Only the covered parts of his skin were affected. There was little or no itching. His general health was excellent. The eruption rapidly and completely disappeared under the use of a 2 per cent. resorcin ointment.

CASE IV.—A young mechanic, of vigorous physique, came to be relieved of a severe "chafing and scalding in the crotch," as he termed it. An inspection disclosed a patch of eruption, roughened, elevated, scaly, and of a deep, almost coppery-red color, with well-defined margins, occupying the perineum and extending down the back of the scrotum and inside of the thighs. The condition had existed several weeks, and defied home treatment, the itching and burning now being extremely severe. Although half dreading to apply any stimulating application to such an intensely irritated surface, I gave him a 2 per cent. resorcin salve, with a simple dusting-powder of oleate of zinc and starch. The irritation subsided at once, and the eruption soon followed suit.

The mere mention of Class 2, the eczemas of the flexures, such as the anus, the groin, or back of the ears, is sufficient to call up a host of cases in one's own recollection, and the same is true of the first division of Class 3, the eczemas of gouty, rheumatic or diabetic subjects. I thus reach my last division, those eczemas due to the effect of general depression:

CASE VII.—H. C., a conductor, aged thirty-nine, as the result of a collision sustained a severe compound fracture of the bones of the left leg, with extensive lacerations. After a prolonged effort to save the limb, suppuration set in, and it became necessary to amputate above the knee. His general condition having become greatly depressed, the wound healed extremely slowly, a distinct anemic heart-murmur developed, puffing occurred under the eyes, and the stump became edematous and waxy-looking, easily pitting on pressure. Just as this depression was beginning to disappear a well-marked eczematous eruption appeared upon the upper and inner part of the swollen stump, well above the wound, and out of reach of the discharges. Under the use of zinc dusting-powders the itch was relieved, and the eruption scaled off and subsided, to reappear at intervals, each time in a milder form, until his general health was practically restored.

In another of my cases an eczema broke out upon the surface of an extensive scar consequent upon severe laceration and crushing of the parts, and ran a most obstinate course.

As an illustration of over-work as a contributory cause I may mention the case of a journalist now under my care, who assures me that loss of sleep or over-strain of any sort always promptly aggravates an eczema from which at intervals he has suffered slightly for some years past.

Dr. George Dock, formerly of Philadelphia, and for three years Professor of Pathology in the Texas Medical College, at Galveston, has been elected Professor of the Practice of Medicine in the University of Michigan, at Ann Arbor.

CLINICAL MEMORANDA.

SHORT NOTES ON RECENT SURGICAL CASES.[1]

By ROBERT W. JOHNSON, M.D.,
of Baltimore, Md.

I wish to present the following cases, selected from my case-book of the past year:

NEPHROTOMY.

Case I.—M. J., thirty-one years of age, white male, married, the father of six children, when seventeen years of age had gonorrhea without complications. Six years ago he had intermitting pain in the left side. He also had attacks of gnawing pain in the left renal region lasting from thirty-six hours to a week, accompanied by fever and slight chill. The pain extended into the left testicle, which swelled and was hot; his urine was high-colored. Two months ago he passed blood with his urine but had no pain at the time. Nausea accompanied the pain; the bowels were regular; there was no cough.

On April 14, 1890, the urine was muddy-looking, frothy and the specific gravity was 1025; the usual urinary odor was faint. It was slightly acid in reaction; boiling did not affect the transparency; the nitric acid test showed a superabundance of urates. Microscopically I found disintegrating and enlarged blood corpuscles, pus, and a soapy reaction with liquor potassæ; no crystals were apparent. There were marked pain and tenderness over the left loin and extending along the course of the ureter to the testicle. My diagnosis was pus in the pelvis of the left kidney, possibly due to an impacted calculus. Dr. Tiffany saw the patient with me. Finding fluctuation and swelling deep in the left groin, he concurred in the diagnosis and in the proposed treatment by operation.

On April 18th, the patient had for four days been suffering with pain, lassitude, and rise of temperature in the evening. With full aseptic precautions I cut through the left groin, one-fourth of an inch below and parallel to the last rib (previously counted), making an incision four inches long and two and a half inches from the spine. Dividing some fibres of the erector spinæ, and with my fingers separating the peri-renal fat, I came down on the sac of the abscess, which was the expanded pelvis of the kidney; I ruptured it with my finger, giving exit to about a quart and a half of thin pus. I washed out the cavity with 1 : 8000 bichloride solution followed by hot water. I found no calculus, the calices seeming soft and the kidney apparently not disorganized or containing any hard point. I sounded the ureter with a probe, but no impacted calculus was to be found. After introducing a large rubber drainage-tube I stuffed the abscess cavity with iodoform gauze. The external wound up to the drain opening was sewed with silk. The patient suffered from shock, but whiskey, hypodermatically, brought him up. The patient made an uninterrupted recovery, his temperature rising once to 101°, from blocking of the drain, which caused a recurrence of the old pain. At present he is able to attend to his work, walking three or four miles a day, and has general good health, although much annoyed by the urinary fistula that remains. The ureter is impervious on that side. He cannot tolerate the gathering of the urine, and after having tried numerous other devices he finds an absorbent cotton pad the most convenient receptacle. He knows that extirpation of the kidney is the only means of relief from this condition; but knowing his surroundings, with a family dependent upon him, I have advised him not to risk it. Fortunately for him no one would imagine he had a urinary fistula, as he is very neat and his urine is not ammoniacal. The local treatment consists in washing out the abscess cavity alternately with bichloride solution, carbolic acid, and permanganate of potash, so that the large surface may not absorb any one drug to his detriment. The capacity of the cavity is now about two ounces. I injected Armenian bole to see if I could find any in the urine from his bladder, but apparently there is no communication between the left kidney and his bladder. His testicles swell occasionally and he has mutterings of pain in his right side, but nothing to warrant the inference that his other ureter is involved.

LITHOTOMY.

Case II.—A. N., thirteen years of age, white, came to America from Bohemia in 1890. He was employed as a tailor and led a sedentary life. He was admitted to St. Joseph's Hospital. He had a collateral tuberculous history on the part of his brother and sister. While on shipboard he had frequent micturition, pain and some blood in his urine. His urine was alkaline, with a specific gravity of 1010 and with pus and blood present. No stone was found, but apparent urethral incrustation near the neck of the bladder. The pain increased until it was almost unbearable, and in spite of sedative and antiseptic injections, including boracic acid, peroxide of hydrogen, a marked degree of cystitis remained, the pain being somewhat relieved by the retention of a soft catheter in the bladder. Further examination of the urinary deposit revealed no tubercle bacilli. The pain continuing, he was examined under chloroform. A stone, encysted or adherent to the right anterior wall of the bladder, was detected, and two days later, after cleansing the bladder with boracic acid solution, with Smith's small-sized lithotomy instrument, I did a left lateral lithotomy. There was but little hemorrhage, easily checked by a plug of iodoform gauze that was removed on the same evening. A stone was removed weighing 201 grains, about the size of a walnut, with phosphatic covering and presenting a corrugated indentation where it had been attached to the bladder. The child expressed great relief at once. His temperature kept about normal until the end of the second week, when the urine ceasing to flow through the wound, but now coming *per urethram*, there was a temporary rise to 102° with some tenderness over the bladder and a re-appearance of cystic urine. Benzoic acid with biborate of soda reduced the temperature at once, with the subsidence of the bladder irritation, and his progress to recovery was not marked by any relapse.

I would call attention to three points in connection with this case: First, the fact that so large a stone was not diagnosticated at the first examination. This I attributed to the fact that it was securely held by its attachment to the anterior wall of the bladder, a rather

[1] Read before the Clinical Society of Maryland, May 15, 1891.

unusual location for stone in children. Again, the phosphatic roughness of the urethra presented an apparent cause for his pain, frequent micturition, etc. Second, the great value of the Smith's lithotomy instrument, which renders the operation so mechanical that it is difficult to go astray in its use. I know this has been urged as an objection to it, and it has been said that anyone can do lithotomy with it, without skill or *tactus eruditus*. The obstetric forceps is mechanical, the plaster splint is mechanical, the ligature is mechanical—the very name of surgery is suggestive of handicraft, and one should welcome any simple mechanism that renders our science as much service as the instrument indicated. The last point about this case is the way in which it illustrates the value of benzoic acid and biborate of soda:

℞.—Acid. benzoic. . . . . gr. xxx.
Sod. biborat. . . . . ʒss.
Aquæ . . . . . ʒiij.
M. et ft. sol. S.—ʒij t. d. in water.

I did not use this combination until after the operation, when the child's temperature went up as the wound-drainage ceased. It acts as a specific, and men who have had much larger experience in these cases than myself tell me that the only objection to its use is that after taking it the patient seems to forget he has a stone and does not return, or declines the operation.

The next case to which I ask your attention is interesting rather from the peculiarity of the injury than from its treatment.

UNUSUAL COMPRESSION.

CASE III.—J. N., aged thirty, an Irish laborer, six feet tall and well proportioned, was caught under a gradually descending weight of ten tons and was compressed against an iron floor three minutes, he states, in a space not over twelve inches deep. The weight descended against his left arm, forcing it in flexed position against his side. He was unconscious when relieved. Blood flowed from his nose, mouth and ears. When seen by me there was great congestion of the face; the eyes were dark-purple from effused blood in the conjunctivæ (the black eye of a prize-fighter); the pupils were normal and there was no paralysis of the tongue. There was great mental hebetude, but the man could be roused. The pulse was slow. Petechial spots of extravasation appeared on the shoulder and purpuric spots in the skin. There was no fracture of the ribs. He was treated by active catharsis with calomel and salts, and cold applications to the head. In eight days he was able to walk about the ward, falteringly at first, but gradually recovered entirely, though when discharged his eyes reminded me of the rear end of the caboose in a night freight-train, as they looked like two red lanterns set in his head. The point of interest is the fact that there was no apparent internal hemorrhage in any of the more vascular organs, but that the compression forced the blood into the skin and through the fragile vessels of the nose, conjunctivæ and ear, rather than into apoplectic foci in the lungs or brain. The latter was no doubt congested, as was indicated by his early mental hebetude and slow pulse.

The two cases I now report are good examples of the satisfactory result of healing under the blood-clot, a method dwelt on by Schede in 1886 and practically illustrated in the masterly results obtained by Prof. Halsted and reported in the Johns Hopkins Hospital Report on Surgery.

COMPOUND FRACTURE OF THE FEMUR.

CASE IV.—J. C., aged fifty-five years, fell eighteen feet, cutting the face and bruising the body, with impacted fracture of the left wrist, simple fracture of the tip of the radius and right wrist, compound fracture of the lower third of the right femur, with an external wound two inches in length. When I saw the case the temporary dressing of bichloride gauze, with which, if possible, all my wounds are temporarily dressed before the patient is forwarded to the hospital, was removed. The external wound was washed with a weak solution of bichloride, and after washing with soap and shaving, catgut stitches brought the margins of the wound together. Iodoform-gauze dressing was applied with pressure by lino bandage, and the leg placed in a long side-splint and pasteboard internal splint with twelve-pound extension. No drainage was provided for. Healing followed *per primam* except at the seat of a small suture-abscess. A plaster splint was substituted in two weeks. The result was satisfactory. There was no infection at the seat of the compound fracture. Contrasting the temperature charts of this case and of another of simple fracture of the femur brought in at about the same time showed that there was greater variation from the normal in the simple than in the compound fracture. In both the variation was very slight.

BURN BY MOLTEN IRON.

CASE V.—E. C., aged thirty years, a colored laborer, accidentally put his left foot and ankle into molten iron as it poured from a furnace, at the same time burning his right foot slightly. He was admitted to the hospital March 6, 1891, with the whole integument of the left foot and ankle, except a small island of skin over the instep, in a charred condition. As it was impossible at the time to say how much of the foot could be saved, it was enveloped in cotton batting and carron oil, and when suppuration began was washed twice a day with permanganate of potash solution. April 6th, one month after his admission, it was apparent that the whole foot could not be saved, as some of the toes were gangrenous and the tendons of the extensors were necrotic; there were still also small sloughs adherent to the foot. At this date the whole surface of the foot, sole and all the ankle, except the islet of skin and the necrotic toes, was granulating and suppurating extensively. I determined to perform an amputation mentioned by Agnew and if possible (though I hardly hoped for success) have the incision unite by first intention. Soaking his foot in 1:10,000 bichloride solution in a foot-tub for twenty minutes before operating and taking aseptic precautions about instruments, dressing, etc., I made a transverse incision over the instep along the edge of the island of skin, disarticulated three cuneiform and the cuboid bones, using Esmarch's bandage and making the plantar flap from the granulation-covered sole. Silk ligatures were used, some difficulty being encountered in securing the plantar arteries. The wound was not washed with any aseptic solution. Boiled water was used in cleansing the sites of the bleeding-points. No drainage was introduced, but the flaps, with their granulating and

edematous edges, were united loosely with silk ligatures. The wound filling with blood from the oozing, gutta-percha protective was applied, then iodoform gauze, then sterilized cotton and lino bandages tightly so as to get pressure that was graduated by the bulk of the cotton, and as there was marked shock the patient was stimulated. I determined not to change the dressing unless there was some constitutional evidence of trouble, as indicated by temperature or pulse. As it was, his pulse was quieter after the first two days than it had been previously to the operation; and except on the evening of the operation, when his temperature rose to 102° (a rise I attributed to reaction after the shock) it did not go over 100°, the greater part of the time remaining at 99°. The discharge from the granulating surface outside the wound, and some no doubt from the blood-clot itself, soon moistened the dressing and it became so offensive that in spite of my previous resolve not to tamper with it unless there was constitutional evidence of infection I removed it on the ninth day. I found evidences of pus over the granulating surfaces of the burn, which had become beautifully less under the non-irritating protective, and the wound apparently closed from end to end along the line of incision; nor could I detect any fluctuation in the wound indicating pus—in fact, so far it presented the same appearance, as far as union was concerned, as if there had been no infecting surfaces in the immediate neighborhood. I trickled bichloride solution 1 : 2000 over the superficial ulceration, reapplied protective, which acts so satisfactorily in preventing the rude annihilation of capillaries by the removal of the adherent dressing, reapplied gauze and sterilized cotton fortified by several turns of plaster-of-Paris bandage. The man continued to do well, complaining of no pain worth mentioning, his pulse and temperature remaining about normal. His appetite was good, he slept well, etc. On the twenty-first day from curiosity I removed the dressing. The incision was firmly united, with no trace of suppuration in the wound. The silk suture showed beneath the granulating surface, which is markedly decreasing, with the same glazed appearance, due to the protective, as was seen at the time of the last dressing. The wound is now well, though the granulating surfaces will continue to heal for some time; the general condition in every respect is good.

I am not able to say exactly what the meaning of this primary union in the presence of pus-infiltrated granulations is. The soaking of the foot in bichloride solution at best sterilized only superficially the outside of the ulceration. It is certain that the incision must have been infected with pus-organisms in large numbers, as I handled the foot and leg and flaps indifferently. The sutures and ligatures were aseptic, yet nothing but boiled water was used to wash the incision; still, in spite of this, the blood-clot (?), purposely left without drainage, had the antiseptic quality of preventing suppuration in the wound, and that too while the external incisions at least were contaminated by the pus in the granulations. The line of incision is not visible except for the sutures purposely left for inspection.

Whether this immunity from suppuration is to be attributed to the phagocytic action of the blood-corpuscles as is taught by the Russian experimenter, or whether it is due to the antiseptic quality of the blood-serum, a later suggestion, I am not able to state—one case neither makes nor mars a theory. It is reported with the hope that it will evoke further light from others who may have secured primary union in amputation through suppurating surfaces, or wish to testify to its infrequent occurrence.

ULCERATIVE ENDOCARDITIS; AUTOPSY; REMARKS.[1]

By FRANK R. ENGLAND, M.D.,
PROFESSOR OF PEDIATRICS, BISHOP'S COLLEGE, MONTREAL.

Ulcerative endocarditis is an interesting and somewhat uncommon disease; some peculiar characters in the following case make it worthy of report.

The patient, J. I. R., thirty-six years of age, was by occupation a locomotive engineer. His father died at the age of seventy-one years, his mother at fifty-four years; one sister died suddenly of heart disease, one living brother has aortic disease, and two sisters are alive and well. The patient has enjoyed the best of health until about two and a half years ago, when he had an attack of articular rheumatism, complicated by endocarditis, which kept him in bed for four weeks. At this time there was present a soft, blowing, diastolic murmur which was transmitted down the sternum and upward along the vessels into the neck. His recovery was apparently good, the murmur nearly disappeared, and he again became, as he was before the attack, a florid, robust-looking man, the picture of health and weighing over two hundred pounds. For the past two summers, beginning about the first of July, he has been annoyed with what he called "hay-fever," characterized by a catarrhal condition of the eyes and nasal mucous membrane, accompanied by sneezing and running at the nose. These attacks had no ill effect on his general health and the symptoms would disappear after a few weeks. During the winter of 1890 he was troubled a great deal by a dry, harsh and irritating cough that resisted all treatment, but disappeared in the spring. In the same year, about Christmas-time, his same annoying cough returned. Nothing in the way of treatment afforded much benefit, and, as the cough continued, his health and strength began to suffer. He lost weight and complained of night-sweats. Examination of the lungs at this time detected no signs of disease and only an occasional dry rhonchus could be heard. About the end of January matters were made worse by domestic affliction, during which time he lost much rest and sleep. He lost courage, became disheartened and obstinate, refusing further treatment, and persisted in continuing at his work, until March 10th, when he broke down. I was sent for and found him greatly changed in appearance. He was thin and worn-looking, and complained, on the least motion (on drawing a full breath, on coughing or sneezing), of great weakness and severe pain over the left lumbar region, making it quite impossible for him to turn in bed. The temperature was 101°, the pulse quickened. During the first six days of his illness his temperature ranged between 100° and 101°. The cough was troublesome, but there was no expectoration and no sign of disease in the lungs could be made out. I remembered his old rheumatic trouble, but had no definite explanation for the

[1] Read before the Medico-chirurgical Society of Montreal, May 1, 1891.

continued though slight pyrexia, the great weakness and nervous prostration present. The latter was proved by his wakefulness, the muscular tremor and irritability, the profuse sweats, whenever he happened to fall asleep, together with the persistency and severity of the lumbar pain. I was therefore compelled to look upon the case as rheumatic and to direct my treatment accordingly. The heart was daily auscultated, and during the first ten days of illness no evidence of acute disease was made out. After this, however, a harsh, loud, double aortic murmur developed and there was soon marked incompetency of the aortic valves, indicated by visible pulsation of the arteries of the head and neck. The symptoms that marked the case throughout were great prostration, violent paroxysms of coughing and profuse perspiration on falling asleep. The expectoration, which became profuse as the disease advanced, was at times clear and tenacious, and at other times sanious. A congestive bronchitis developed. In spite of a fairly good appetite and of apparently good assimilation of food, the patient became anemic, weaker and more emaciated. Owing to the cough, he could get little sleep or rest at night. Throughout the disease the temperature varied from 99° to 101°, the respiration from 36 to 46, and the pulse from 96 to 120. At no time was pain in the cardiac region or palpitation complained of. There were no rigors. Rheumatic pain and tenderness developed in the right shoulder, lasting for a few days during the third week, and there was some vomiting a few days before death, which, due to heart-failure, occurred rather suddenly April 23d, forty-four days after the patient took to his bed.

At different times during his illness the patient was seen by my friend and confrère, Dr. Hutchinson; Drs. Armstrong, Rodger and Geo. Ross also saw the case in consultation with me, and from the severe constitutional symptoms and great prostration all considered the cardiac lesion to be of a grave and destructive nature. The possible diagnosis of ulcerative endocarditis was entertained early in the disease and Dr. Ross, who saw the patient ten days before death, was strongly inclined to consider the case as one of malignant endocarditis, though there had been no rigors, no septic temperature and though it did not occur in the course of pyemia, pneumonia, scarlatina, diphtheria or ague, diseases in which, according to Osler, it is met with most frequently. The autopsy showed vegetations one-eighth of an inch long on the flaps of the aortic valves. In one of the flaps there was a perforation through which a bristle could be passed. This damaged condition, as pointed out by Osler and others, is a frequent concomitant. A stained microscopic section showed micrococci in moderate quantity. The aperture in the flap was, at the time of examination, blocked with recent lymph. Such a condition demonstrates the possibility of an intermittent diastolic murmur.

The American Electro-therapeutic Association will hold its first annual meeting at the hall of the College of Physicians, Philadelphia, September 24, 25, and 26, 1891. Dr. G. Betton Massey, of Philadelphia, will preside. An invitation of attendance is extended to physicians interested in the discussion of electricity in medicine.

ARTIFICIAL DRUMS.[1]

BY LAURENCE TURNBULL, M.D., PH.G.,
OF PHILADELPHIA, PA.

THE following list shows the various kinds of artificial drum-heads that up to the present time have been introduced: Moistened cotton pellet, Mr. Yearsley; rubber disc (Toynbee) with silver wire; cotton ball attached to thread; disc of adhesive plaster; disc of sublimated gauze, Dr. L. Turnbull; disc of oiled silk, Dr. C. M. Thomas; cotton pellet fixed by collodion, Dr. Barr; disc of sized paper, Dr. C. J. Blake; compound disc of India-rubber, cotton-wool and flannel, Mr. George Field; solid piece of India-rubber, Dr. Burkard Merian; India-rubber tubes as long as the canal, Professor Politzer; India-rubber disc attached to the tube, Professor Lucas; circular patch of pellicle of egg, Dr. Walter Downie; disc of stout linen with cotton thread soaked in vaselin, Dr. F. M. Pierce; cylinder of gold, Dr. H. B. Richardson; glycerin thickened with tannin, Dr. Michael; plug of boric acid powder, Dr. Farquhar Mattheson. Katz advocates celluloid drums, consisting of a disc of this material with a roll of wick of cotton attached to the centre as a handle. Ward Cousins has suggested antiseptic lint artificial membranes compressed or shaped like a hat with a handle. Attention was called to these, the most recent I have tested, but not with the satisfaction I expected.

Gross frauds are being practised by the sale of *fraudulent artificial membranes* to persons so profoundly deaf as really to require only a hearing trumpet; indeed, there is not one deaf person in fifty or even a hundred who is found, by careful examination of the ears, to be suitable for an artificial membrane, and yet I find all classes of deaf individuals are found filling the offices of quacks who, without even a glance into the the ears of these deaf patients, bring forth a box containing two artificial drums of rubber, with a handle of rubber and silk thread, and with a pair of small forceps, a bottle containing a mixture of glycerin, alcohol and ether, and a small rubber syringe, as the cure-all.

I present one of the most recent of the advertised sets of drums, which was purchased in Philadelphia recently by a patient of mine, from an individual from the "Nutmeg State." My patient was not able even to hear the tick of a clock or watch, yet she was not examined, nor allowed even to test the artificial drums until after paying for them. After testing them most carefully for two weeks, the person who sold them having by that time left Philadelphia, she sent them to me to be placed among my collection. I have carefully and conscientiously tested all the varieties of these drums, and do not find anything better in suitable cases than antiseptic gauze, wool, absorbent cotton, oiled silk or fine rubber. These are charged with liquid vaselin, with menthol—20 per cent. solution—and placed properly in the ear. In most cases they act as protectors—rarely, however, improving the hearing.

THE ABUSE OF SYRINGING WITH VARIOUS FLUIDS.

In some of the most severe and protracted cases of acute middle-ear disease which have been under my

[1] Delivered before the Medical Society of the State of Pennsylvania, at its meeting in Reading, Pa., June 5, 1891.

care or sent to us, either in children of scrofulous or tuberculous parents, the constant syringing with fluids—with irritant mixtures, or even impure water—is a most pernicious habit, and should be frowned upon. If a liquid is required, nothing should be employed but a solution of the peroxide of hydrogen, both for the nose and ears—one part of peroxide to three of distilled water. The ears should afterward be carefully packed with absorbent cotton and finely levigated boric acid, with a small quantity of menthol rubbed into the powder.

POWDERS FOR TREATING THE EAR.

Since the discovery and introduction of that most valuable agent, boric acid, by Betzold, numerous agents have been lauded for a time as being superior to it, as, for instance, "resorcin," and several others of the tar or coal derivatives; but, although praised by several aurists of Italy and of this country, they were found to exercise a most irritating and injurious influence upon the ear. Iodoform has been brought forward, and in proper and specific cases it is excellent, and although not a true antiseptic, has retained its place. This was followed by "iodol," which had a short life. "Aristol" is a new agent, and I would like to state that there are many objections to such fanciful names, when its own proper name is at once simple and descriptive. This agent has been highly praised by medical men in Europe and in this country. It was termed a universal curative agent in almost every disease. In skin disease it was stated to be wonderful, and pronounced harmless. In chronic rhinitis and in gynecological practice it was most favorably reported; also in ophthalmology and other branches of medicine. In ear disease I, with others, have given it a fair trial, but it has not been found a suitable remedy in my hands. It is a dithymol-diodide, or, more simply, an iodide of thymol, and is most simple in its preparation; it is made by adding a solution of iodine in iodide of potassium to an alkaline solution of thymol. Aristol only contains 45–48 per cent. of iodine, which is less than half that of iodoform; and while it does not follow that the substance containing the most iodine will be the best antiseptic, or even possess such properties in any degree, I know what iodoform is, and I think it may be fairly stated that aristol is not nearly its equal.

RUPTURE OF A DUODENAL ULCER.

By C. A. HAMAN, M.D.,
RESIDENT PHYSICIAN OF THE CHILDREN'S HOSPITAL OF THE MARY J. DREXEL HOME.

The following case, on account of its rarity and the difficulty of diagnosis, is deemed worthy of being placed on record:

D. M., aged ten years, had stumbled and rolled down a hill in the park. Within one-half hour he was taken to the Children's Hospital of the Mary J. Drexel Home. On admission he was found to be slightly dazed; his temperature was 101.4° F.; his pulse 110, and of fair volume; the abdomen somewhat tympanitic and tender on pressure; there was a small lacerated wound of the chin. About four hours after admission he began to get pale, the pulse became imperceptible at the wrist, the tympany and tenderness increased, and the respirations were very frequent and shallow. Repeated vomiting set in; the vomiting was not stercoraceous or bloody. The patient died within three hours after the symptoms of collapse presented themselves.

At the autopsy there was found a ruptured ulcer of the duodenum, situated about ten inches from the pylorus. The peritoneal cavity was full of intestinal contents. No blood was present, and no other ulcers of the intestinal canal were found. The mesenteric glands were enlarged. No other pathological changes or evidences of injury were found in any of the viscera. Prior to the accident the boy had complained of no symptoms referable to disease of the gastro-intestinal tract.

For permission to publish this case I am indebted to Dr. Carl Frese, Chief Resident Physician of the German Hospital.

NOTES CONCERNING THE TREATMENT OF LEPROSY.

By W. THORNTON PARKER, M.D. (Munich), M.M.S.S.
of Salem, Mass.

In an article on "The Treatment of Leprosy," in the July number of the *American Journal of the Medical Sciences*, Dr. Mitra recommended the use of gurjun oil, both internally and locally. I beg to submit the following treatment:

℞.—Quininæ sulph.	. . . .	℥ss.
Tr. ferri chlor.	. . . .	fl℥ss.
Syr. simpl.	. . . .	fl℥ss.
Aquæ	. . . . qs. ad	fl℥vj.

S.—One fluidrachm three times daily, ten minutes before meals.

℞.—Syrup. trifolii comp.

S.—Two fluidrachms half an hour after meals.

Locally, the glycoboron cerate (boroglyceride, 25 per cent.) may be applied. This ointment will be found peculiarly valuable in the treatment of the ulcerative stages of both the tubercular and the anesthetic varieties. Combining powerful antiseptic properties with its healing and soothing action, it is especially indicated to prevent fetor. It is less irritating and in every way superior to creolin. This combination of tonic, alterative and local antiseptic treatment is most confidently recommended. I have used this mode of treatment with excellent results in a recent case of chronic eczema, in which the face, trunk and extremities were simply covered by the disease. Within a short time the irritation greatly subsided, and the normal color of the skin is rapidly returning. After two or three weeks of the iron and quinine tonic treatment, I employ the new but reliable preparation of iron known as the elixir succinate. The general indications in the case of lepers are cleanliness, antiseptic applications, alteratives and tonics. This plan of treatment will, I am sure, be found at least as efficacious as that advocated by Dr. Mitra.

CURRENT LITERATURE.

THE PATHOGENY OF MALIGNANT JAUNDICE.

Carreau remarks upon the analogy of the symptoms and lesions which exist in the grave jaundice of certain diseases engendered by very different causes, but which have, perhaps, as a final result an

identical chemical action upon the blood. Among these forms of jaundice, in addition to those which may be called essential, is that associated with poisoning by phosphorus, and those of yellow fever and the grave bilious fever, alongside of which may be classed that of the fever of the Creole children with black vomit. To these Carreau would add the grave jaundice of the fever with black urine (bilious hemoglobinuria), which, from its great resemblance to grave typhus, has received the name of "yellow paroxysms." Carreau thinks that this name should rather be reserved for the fever with black vomiting alluded to above. This fever is especially observed in Creole children under twelve years of age. On the third day albumin appears in the urine, and black vomit occurs, with a slight degree of jaundice, especially marked in the conjunctivæ, but at times scarcely apparent. This increases very much after death, which occurs on from the fifteenth to seventeenth day, after some ataxo-adynamic phenomena, with multiple hæmorrhages in the cellular tissue, especially of the digestive passages.

The diversity of the alterations in grave jaundice, as well as in yellow fever and phosphorus-poisoning, is the proof that the primordial lesion is a humoral alteration, and that the organs are affected secondarily, more or less, according to the degree of the gravity and the duration of the sickness. Thus, according to the rapidity with which death has occurred, various alterations will be found, from simple affection of the hepatic cells (the liver appears then scarcely altered to the sight) up to fatty degeneration and destruction of the cells in large number. The organ in this case appears to diminish one-half. Alteration in the kidneys progresses in proportion to the change in the liver, proving thus the existence of a general cause which acts upon these organs at the same time and in the same manner. But, whatever may be the duration of the sickness, there are some lesions which are always found to be the same. These are changes in the blood, and multiple hemorrhages which are the consequence of its alteration. Yellow fever, grave jaundice, phosphorus-poisoning, and the fever with black urine, all reveal a similar condition of the blood, with disseminated hemorrhages.

As to the pathogeny of grave jaundice, two factors are necessary—the blood and the bile—but experience has long since proven that the mixture of these two bodies is inoffensive. The symptomatic yellowness due to the biliary retention may last for weeks and months without altering sensibly the health, when, all at once, under some unknown influence, the phenomena of grave jaundice show themselves and carry off the patient in a few days. It is safe to say, with Trousseau, that one never knows how jaundice will end. As to what has brought the change, pathological anatomy, physiology and chemistry have sounded the problem in vain. Carreau has thought that neither the microscope, although it were extended to the utmost limits of vision, would comprehend the phenomena which occur within the organs, nor yet chemistry, which is still powerless to determine whether methemoglobin presents a degree of oxygenation less or superior to hemoglobin. He thinks, however, that a powerful method of research which is too much neglected, namely, the spectroscope, would reveal the phenomena in full formation. A mixture of fresh blood and bile presents the spectrum of hemoglobin and of the biliary pigments. If, now, this mixture be treated with ammonium sulphide, the spectrum of reduced hemoglobin is given at the same time that the obscurity of the biliary pigments persists. This is proof that the mixture of bile with blood, such as is observed in jaundice, is not noxious, but is reconcilable with relative health. Blood which is not fresh, but has been treated with the sulphide of ammonium, gives the spectrum of reduced hemoglobin at the same time that the band in the red disappears. This is the characteristic spectrum of acid methemoglobin. This same blood, with the addition of a small quantity of bile, submitted to the action of the reducer, still gives, with the disappearance of the band in the red, the spectrum of reduced hemoglobin, but with an interesting modification: the band of Stokes, in place of being uniform as usual, was scarcely shaded in its left three-fifths, and very pronounced, on the contrary, in its right two-fifths. With a larger quantity of bile a more remarkable result was obtained: the band of the methemoglobin always disappeared; in its place the band of reduced hemoglobin appeared, in the middle of which the first band of reduced hematin made its appearance. Agitation regenerated the oxyhemoglobin, which would replace at times the reduced hemoglobin, in the centre of which the reduced hematin would appear again.

Carreau concludes that since the bile exists in the blood permanently, the slightest cause tending to produce an irritation of the blood may give rise to the phenomena of grave jaundice. The blood has then undergone an alteration which has modified the hemoglobin and has converted it into acid methemoglobin. To avoid this grave accident he advises his patients afflicted with jaundice to avoid all fatigue and excesses and too sudden changes of temperature, and to wear flannel underclothing and woollen hose. Quinine is administered only in small doses, or if large doses are needed, they are given concurrently with the essence of ozonized turpentine to supply the oxygen which will be consumed in the conversion of a certain quantity of hemoglobin into methemoglobin by the action of the quinine.—*La Médecine Moderne*, No. 11, 1891.

A CASE OF WORD-BLINDNESS WITH AGRAPHIA.

DEJERINE, in a paper in *La Médecine Moderne*, No. 13, 1891, says that certain authors (Exner, Charcot) have admitted the existence of a special centre for the coördinated movements of writing, which centre is located in the posterior portion of the second frontal convolution of the left side. This localization is based upon the researches of Exner, but the facts upon which it rests are not absolutely demonstrative. The faculty of writing is directly subordinate to that of reading mentally. It consists only, according to the expression of

Wernicke, in the act of copying the optical images of the letters and words, and the movements of writing are in all points comparable to those which are necessary in copying any linear design whatever. But there is nothing to prove that the act of writing depends upon a special and autonomic centre which plays for writing the same *rôle* that the convolution of Broca does for the spoken language. To demonstrate the existence of an independent graphic motor centre it would be necessary to secure a clinical case of *pure, isolated agraphia*, followed by an autopsy, in which a minute anatomo-pathological examination would reveal as the only alteration a lesion of the presumed centre without concomitant lesion of the centres of tonal and optic memories or the convolution of Broca. But up to the present time no case of this kind has been reported; the rare autopsies of agraphia which have been published have all treated of complex clinical cases with extensive or multiple anatomo-pathological lesions.

The writer then reports a case of complete word-blindness with probable hemianopsia and agraphia. The patient was a gardener, sixty-three years of age, who at the age of fifty-six years had had a very slight attack of right hemiplegia, not accompanied by troubles of speech. In January, 1890, one morning he found that he could not read his paper, and on the 12th of February he was admitted to the ward of the hospital. At that time there was a scarcely appreciable paresis of the right arm and leg. The face was intact and also the general and special sensibilities. The patient showed no trace of word-deafness, but understood all that was said to him. He was unable to understand printing or writing. When presented a paper or written phrase, he would look at it for a moment and then say, "I do not understand it." He was also unable to name the letters (word- and letter-blindness). He was able, however, to read his name, and could recognize and name every object presented to him. There was some trouble with speech. The patient, either in the act of speaking spontaneously or while repeating some words, would take one word for another, so that at times it was difficult to understand him (paraphasia). He was unable to write anything except his own name, and held his pen as a child would who was learning to write for the first time. He was under treatment, with some improvement, until November 20th, when he died. The autopsy revealed a yellow plaque, localized on the lower three-fourths of the angular gyrus of the left side and terminating in a point in the external parieto-occipital fissure. The rest of the cortical surface was absolutely intact. The diseased mass penetrated in a conical shape into the subjacent white matter and divided the radiations of Gratiolet. In the right hemisphere were two spots of softening of the size of a small nut, one in the outer portion of the lenticular nucleus, the other in the anterior portion of the optic thalmus, by their union destroying the knee of the internal capsule.

Notwithstanding the clearness of the symptom of word-blindness, this case cannot be placed in the category of observations of word-blindness, pure and isolated, as reported by Charcot, Landolt, and others. In these cases the alexia was not accompanied by any trouble in writing; spontaneous writing, as well as writing from dictation, were performed easily. The patients wrote, but could not read. In the above case, however, the patient could not write at all. It is therefore a case of peculiar interest.

MEDICAL PROGRESS.

The Bacillus of Leprosy.—Kanthack and Barclay (*British Medical Journal*, June 6 and 13, 1891), members of the Leprosy Commission, report the results obtained by attempts to cultivate the bacillus of leprosy by introducing into culture-bouillon bits of leprous tissue taken from the ears of lepers. Cover-glass preparations of the bouillon revealed free bacilli identical morphologically and in their reaction to stains with the bacilli of leprosy. Inoculation of agar and gelatin-tubes resulted in the formation of a pellicle in which similar bacilli were found. Potato and egg-cultures were unsuccessful. The results of inoculation in animals were yet to be determined.

Rake and Buckmaster (*British Medical Journal*, June 27, 1891), also members of the Leprosy Commission, have succeeded in cultivating the bacillus of leprosy in serum from a blister. In two cases a blister was raised over a tubercle on the face of a leper and another blister over the normal skin of the back. A portion of the fluid from each blister was taken in a sterilized capillary tube, which was kept at the temperature of the body. Previous examination had shown that the fluid in a blister over a tubercle contained leprosy bacilli. On microscopic examination of stained preparations of the fluid placed in the tube, leprosy bacilli were found. Successful cultures were also made in bouillon, gelatin and agar.

The Detection of Oleomargarin.—Leffmann and Beam have devised a modification of the Reichert distillation process for butter, that possesses the advantages of completeness and of being rapidly carried out. Saponification is effected by means of a mixture prepared by adding twenty-five c.c. of a clear 50 per cent. solution of sodium hydroxide to 125 c.c. of pure re-distilled glycerol, and boiling from fifteen to twenty minutes, to evaporate the greater portion of the water.

About five grams of the clear fat are weighed out in a flask in the usual manner, ten c.c. of the alkali-glycerol added, and the flask heated over a Bunsen burner. The mixture may foam somewhat; this may be controlled and the operation hastened by shaking the flask. When all the water has been driven off, the liquid will cease to boil, and if the heat and agitation be continued a short time longer complete saponification will be effected, the mixture becoming perfectly clear. The whole operation, exclusive of weighing the fat, will require less than five minutes. The flask is then withdrawn from the heat, and the soap dissolved in ninety c.c. of water. The first portions of water should be added drop by drop, and the flask shaken between each addition, in order to avoid foaming. When the soap is dissolved, fifty c.c. of diluted sulphuric acid—twenty-five c.c. of the concentrated

acid to the liter—are added, a piece of pumice dropped in the flask and the distillation conducted as usual, until 100 c.c. of distillate are collected.

Blank experiments have given a distillate requiring from 0.2 to 0.3 of deci-normal alkali.

For the identification of "straight oleos" it has been found sufficient to carefully measure three c.c. of the clear, melted fat, using one-half the quantity of the reagents.

The alkali-glycerol is quite viscid when cold. It should be kept in a flask closed with a rubber stopper and heated when the measured portion is to be taken.

The Relation of Acetonuria to Digestive Derangement.—As a result of observations in eighty cases at Nothnagel's clinic, at Vienna, LORENZ (*Zeitschr. f. klin. Med.*, Hefte 1, 2, 1891) concludes that acetonuria is so constant in cases of digestive derangement of varied kinds as to be considered characteristic. A distinction between diaceturia and acetonuria cannot be made, because the variation in clinical symptoms is slight and quantitative, and in most severe cases a combination or alternation of the two conditions is the rule. The symptoms heretofore ascribed to the action of acetone or of diacetic acid are probably produced by the action of toxic substances the conversion of which into acetone has been checked by imperfect oxidation. Albuminuria, present in some cases, did not appear to be dependent upon the action of acetone or of diacetic acid. Acetone, in varying quantity, was found in the contents of the stomach and intestines. In cases of primary gastro-intestinal catarrh, acetone was almost invariably found in the contents of the stomach and intestines; in secondary catarrh, usually nervous in character, the presence of acetone was exceptional. In two cases, one of uræmic vomiting and one of hysteria with intestinal symptoms, in addition to acetone and diacetic acid, oxybutyric acid was also found in the urine.

Dermatol—a Substitute for Iodoform.—HEINZ and LIEBRECHT (*Berliner klin. Wochenschr.*, June 15, 1891) have given the name dermatol to the basic gallate of bismuth, which is said to be a fine, odorless, insoluble, saffron-yellow, non-hygroscopic powder, unchangeable by air or light. The remedy has been used with good results in surgical, gynecological and dermatological practice. It commends itself as an innocuous, sedative, antiseptic drying powder.

Treatment of Congenital Ptosis by Means of Naphtholated Catgut.—DRANSART has devised an operation for the relief of congenital ptosis, in which an artificial tendon, created from the frontal muscle, takes the place of the absent or atrophied levator palpebræ. The new tendon is made by means of subcutaneous sutures uniting the superior border of the tarsal cartilage with the superciliary muscle. The success of the operation depends upon the asepsis of the sutures and placing them in the deep, connective-tissue layer of the skin. Sterilized catgut has answered admirably, except that it is absorbed in the course of two or three days, while twelve to fifteen are required to obtain a suitable artificial tendon. DEHENNE has found that by preparation with a solution of naphthol the rapidity of absorption of catgut may be sufficiently retarded so as not to jeopardize the success of the operation. He reports a case in which the result obtained was excellent.—*Journal de Méd. de Paris*, May 24, 1891.

Hyperemesis Gravidarum.—In an address before the Obstetrical Society of Berlin, KALTENBACH (*Zeitschr. f. Geburtsh. u. Gynäkol.*, Bd. xxi. p. 200) expressed the view that the obstinate vomiting of pregnancy was hysterical, pregnancy acting as a peculiarly favorable exciting cause of hysteria. The view is supported by the perverse aversions and sensations, the sensory disturbances, the psychic irritability and depression, and the secretory vasomotor anomalies that accompany equally pregnancy and hysteria. It thus follows that the induction of premature labor should be reserved as a last resort. The treatment should be rigidly anti-hysterical: the administration of bromides, the application of cold douches and change of surroundings.

Hairy Tumor in the Stomach.—BOLLINGER (*Münchener med. Wochenschr.*, June 2, 1891) reports the case of a girl, sixteen years old, who, for two and a half years, had presented symptoms of gastro-intestinal catarrh—anorexia, vomiting, abdominal pain and chilliness; the stools became liquid; there was insomnia; ultimately only liquid nourishment could be taken; a hard tumor was detected in the epigastrium; death finally resulted from exhaustion. At the post-mortem examination the stomach and duodenum were found distended with a great mass of hair. It was subsequently elicited that, as a child, the patient had been in the habit of pulling out hairs and drawing them through the mouth, though she had not been known to swallow any. Records of but eight other cases of the kind have been found in literature. The majority occurred in females. Analogous conditions have been found in dogs, in ruminants, in pigs and in horses.

Injections of Strychnine for Diphtheritic Paralysis of the Palate.—ROSENZWEIG expresses surprise that the treatment of diphtheritic paralysis by injections of strychnine is so little known. His own attention was attracted to the method by a publication by Henoch's. Rosenzweig reports four cases of diphtheritic paralysis of the palate which he has treated successfully with hypodermatic injections of strychnine. Three of the patients were girls, and one was a boy; the ages ranged from six to twelve years. The usual symptoms of palsy of the palate—nasal voice and regurgitation of food through the nostrils—were present. The neck was selected as the place for the injections, the dose given being from two to three milligrams ($\frac{1}{32}$ to $\frac{1}{20}$ of a grain), and it was repeated daily. In the first case the nasal speech and difficulty in swallowing disappeared after five injections, but the patient seems to have remained under the strychnine treatment, combined with tonics, for twenty days. In the second case the patient recovered in nineteen days. In the third case all paralytic symptoms disappeared in nine days, while in the fourth case the paralysis of the palate was overcome after three injections. Nothing is said to indicate that there were any bad effects from the doses of strychnine employed, though they are rather large for children.—*Therapeutische Monatshefte*, April, 1891.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, AUGUST 1, 1891.

MEDICAL ADVICE WITH MEDICINES AT SEVENTY-FIVE CENTS A YEAR.

IN the last number of a highly esteemed English exchange there is a very suggestive letter from a correspondent, who frankly confesses that he is regularly attending children at the rate of fifty cents a year, and adults at seventy-five cents a year, medicines included, and he is doing this even though the patients live three miles away. The writer justifies himself in this way:

"I think we may justifiably feel some pride that we have a higher aim than simply working for pay, and that the care and attention which we give to any particular patient is not governed by the amount of the fee. What shall be said of the hospital physician who gives his services for nothing at all? often thereby depriving the humbler practitioner of patients who could well afford to pay a moderate fee. Besides, is there any greater dignity in demanding a higher than a lower fee? Is there any dignity in taking fees at all, or is the whole of the nobility and dignity dependent on the spirit in which the work is done?"

This defence gives glimpses of certain characteristics and social conditions of English life that provoke sad and serious thoughts. It also stimulates questions as to the beam in our own eye. With us there is certainly not any such widespread poverty as that of which we catch the hint between the lines of the correspondent. It is commonly said that as yet in America one can make a decent living by the practice of medicine, without stooping to the five or ten or twenty-five cent fees not uncommon in England.

But with us there are several considerations to modify our self-content. First, it may be noted that gratuitous treatment at the private office is very much more common with us than in other countries. It comes natural to the American character to ask a good-sized fee, or be quite as willing to let the service go purely *gratis*. We consider compromise beneath our dignity. It is said that a friend of a prominent New York lawyer sent the legal light a check for $500 in gratitude for a bit of advice incidentally given with a passing handshake. The check was returned with the curt reply that his smallest fee or retainer was $1000. In medical practice there are similar habits of thought and feeling, and the average of fees and non-fees greatly reduces the supposed regular charge.

In the next place, the thin edge of the wedge is being driven in much faster than is commonly confessed or generally known. It is true that homeopaths are very numerous who give advice and medicines for fifty cents a visit, and not infrequently for twenty-five cents. Willingly or unwillingly, physicians are forced to compete by "meeting" the quack's price.

Another phase is shown in the formation of medical clubs. These are not at all uncommon, and a doctor is hired by the year at a very low rate. Various fraternal organizations succeed by this plan in getting their members and the families of their members treated for merely nominal fees.

The next step in the *descensus Averni* is that taken by the drug-store doctor. The writer once saw a physician enter his drug-store, and passing along the rows of waiting patients briefly learned the symptoms each complained of, in the presence and hearing of all the others. He then prescribed, and the prescription was at once handed to the clerk. There was no charge for the advice or prescription, the medicine alone being charged for. Sometimes the doctor has a private office behind or within the store. More rarely the office may not be connected with the store.

The dispensing druggist must not be forgotten. However undignified, and even illegal, this method of evading the physician may be, it is wretchedly

common. "Give me something for my headache," "for rheumatism," "for stomach-ache;" "give me a dose of antipyrin," "of chloral," etc., are the demands made of the druggist many times every day. He rarely refuses.

The last and lowest depth is the hospitals and dispensaries, emulous of each other, and running a competitive race for patients. In the letter of our New York correspondent published July 18th we see how the patronage of well-to-do people is sought by the attendants of clinics founded "for sweet Charity's sake," medicine and advice being dispensed gratuitously to those with no claim or right to them, to the degradation of the patient, with injustice to the young and struggling physicians, and in defiance of the objects of those bequeathing the funds. As regards a large proportion of American out-patients it must be admitted that they are well able to pay something for their medical treatment, however small the amount might be. The self-respecting visiting and resident physicians of these charitable institutions should spontaneously do away with the abuse, and form rules and establish habits that will bar out those that could pay. It is quite beyond comprehension that members of a noble guild like ours should be so destitute of *esprit de corps*, so reckless of the wrong done the younger members of the profession. Unless reform come spontaneously and quietly, it must sometime come from without and brutally. Those who supply the funds will learn of the way their charity is being used to wrong both patient and physician, and supplies will stop with a suddenness born of righteous indignation, but necessarily followed by other evils. Moreover, young physicians would be better than human if they stood calmly by and allowed their proper *clientèle* to go in crowds to the dispensaries and hospitals to be treated gratis by men whose practices are established. They will meet such useless and brutal competition by establishing other and rival institutions, or by taking up one or more of the methods before described. These things, as we have tried to show, are already well under way, and with true American earnestness, pushed by the facts of a rapidly increasing proportion of practitioners to population, as also by the growing poverty of the city masses—when war is fully declared, it will not be exactly "war with rose-water." The net result will be a sharp lowering of professional dignity, a ruinous cutting and reduction of professional fees, and the further entrance into medicine of commercial customs and auctioneer methods.

In the meantime, will those who have the remedy in their hands remain satisfied to let things drift, and drift, and still drift?

DRUMMERS FOR DOCTORS.

WE rubbed our eyes, re-cleansed our spectacle-lenses, looked again at the journal cover, made sure it was not a summer theater we were in—but had at last to confess that the words stood as given below. The periodical is "our esteemed contemporary," *The Journal of the State Medical Society of Arkansas*, and in its "Miscellany" there appears without comment or explanation the following:

"LIST OF DRUMMERS FOR DOCTORS IN THE CITY OF HOT SPRINGS, ARK., TO WHOM LICENSE HAS BEEN ISSUED IN CONFORMITY TO AN ORDINANCE PASSED JUNE 17, 1889."

Since we do not wish to give a free advertisement to these gentlemen we can only explain that the list comprises the names of twelve doctors, each followed by the names of his "drummers." One doctor has but one drummer, five have two, one has three, two have five, one has six, one ten, and one has eleven — fifty-one men "touting" and "heeling" for the doctors of one small town!

The City Clerk swears the list is a true abstract of the office records, and a note appended explains that the "hotel and doctor drummers" are by ordinance required to take out a license and wear badges showing their vocation. (What excellent devices and mottoes for these drummers' badges might be found in the medieval "Dances of Death," or copied from the old Flemish painters of resurrection scenes. Picture, for example, the fright and resistance of some fleshless, sin-eaten old *roué* being pulled with frolicsome fury by a dozen satanic minions, happy at last in securing their long-awaited prey!)

Will our contemporary inform us if the undertakers of the city also have "drummers," and if these ply their persuasive powers upon all invalids arriving at Hot Springs? And finally, it might be well to know if the city cemetery is a stock company, and how many shares are owned by the "doctors" and their "drummers."

What a fine hint the report might give Gilbert and Sullivan, or the concocters of modern opera bouffé run mad! Can anything be imagined more uproariously funny?

But there is a mawkish suggestiveness in it that reminds one somewhat of the clown that laughed, and laughed, and laughed again, simply at the thought that the devil had him by the ear and that he was at last and actually being marched straight to—hell!

HUMAN VIVISECTION.

SOME three years ago HAHN,[1] a Berlin surgeon, reported the experimental inoculation of six pieces of carcinomatous tissue taken from one breast of a woman and transplanted into the other breast. In fourteen days the grafts had united, and in four weeks the microscope showed the tissues about the transplantations to be carcinomatous. Strangely enough, this observation seems to have passed unnoticed and uncondemned even by those that are now very properly shocked at recent similar procedures. Latterly, according to the daily papers, Dr. LEIDIG, of Berlin, charges Dr. BERGMANN and Dr. HAHN with having performed repeated experiments of the same kind, and, if the newspaper report can be trusted, Dr. BERGMANN thus meets the threatened official inquiry:

"My conscience does not reproach me in the slightest experiment. I have not inflicted on the patients a moment's pain nor shortened their lives a minute. This outcry has not affected my practice. My patients are arriving from all parts of the world."

Again, in the Paris Academy of Medicine, PROFESSOR CORNIL has just reported two similar inoculation experiments, performed in Paris, "by a stranger," upon two women, while anesthetized and without their consent.

These things are, happily, at last arousing a cry of indignation throughout the civilized world. If an enemy of modern scientific medicine can be supposed to exist, he could not inflict upon her a more diabolically effective blow than is thus given by members of her own household and faith. Fanatics will pounce upon these facts and use them with all the zeal of half-knowledge and the fury of unrestrained sentimentalism.

It is indeed astonishing that a great surgeon should calmly dare the indignation of the civilized world and justify his course by his lack of conscience and his worldly success.

We hope later reports will bring better news and show that not even one physician has been so thoughtless of the good of his guild, and so reckless of his own final fame as to give utterance to such "noon-day vices and brazen-browed iniquities."

[1] Berl. klin. Wochenschr., May 4, 1888.

HOMEOPATHIC LAWS.

IN reference to the communication of our correspondent, inserted elsewhere in the current number of THE NEWS, we would add a word as to the essentially unscientific attitude of mind evinced in the tacit assumption that a therapeutist must be governed by any so-called "laws" whatsoever. The scientific type of mind knows nothing, and will not allow itself to know anything, concerning any law of "similars" or of "contraries." It forms judgments only upon evidence, without the domination of any deductive law or principle. It seeks physiological results, whether obtained by small or by large quantities of a drug. The fundamental reason that sincere homeopathy is a disgrace to modern civilization, and must eventually be buried in deserved oblivion, is that in method it is deductive instead of inductive, that it is pursuing the chimeras of a crazy medievalism and of metaphysical will-o'-the-wisps, instead of seriously seeking to know facts and to understand their lessons.

But above and beyond the type of homeopathy that is sincere there is the type that is insincere. The cunning sharper is more dangerous and execrable than the foolish weakling, and it cannot be doubted that the number of those that believe and practise HAHNEMANNIAN homeopathy is extremely small as compared with the great majority of those that neither believe nor practise the follies that their foolish patients think supremest wisdom. If the imbecilities of speculative homeopathy are disgusting, the hypocrisy that for gain pretends to believe them is a stench in the nostrils of all good men.

CORRESPONDENCE.

MONTREAL.

Visit of Mr. Ernest Hart—Branch of the British Medical Association—Changes in the Staffs of Medical Schools—Medical Education of Women—An Interesting Medico-legal Question.

MR. ERNEST HART, the well-known London surgeon and editor of the *British Medical Journal*, accompanied by his distinguished wife, has been "doing" the country, and spent a few days in Montreal. He was taken in hand by Dr. Hingston, of the Hotel Dieu, and matters of interest, scientific and general, pointed out to him, and every attention was shown him to make his short visit pleasant. He was dined at one of our fashionable clubs. A hurried meeting of some of our leading medical men was held in the rooms of the Medico-chirurgical

Society, and Mr. Hart explained the working of the British Medical Association, the largest medical corporation in the world. Branches throughout the Empire are in existence, and one was suggested for Montreal. As a result of this meeting, a number of names were given in and a branch decided upon. Dr. Hingston is to be President, and J. Chalmers Cameron, M.D., Secretary. For the annual subscription fee of $5.25, the substantial return of a copy of the great London weekly, the *British Medical Journal*, is assured to each member.

The teaching season being over, the usual European trip is being indulged in by several of our well-to-do M.D.'s. Next fall a good deal of change will be noted in the staffs of our four medical schools. At McGill, pathology is to have a chair and a salaried professor. The work has heretofore been done by a lecturer, Dr. Wyatt Johnson, who recently resigned. Dr. H. A. Lafleur, for some time first assistant to Dr. Osler in Baltimore, has returned to his alma mater, and will assist Dr. Geo. Ross, sub-dean, in the work of clinical and didactic medicine. At Bishop's College, Dr. Lapthorn Smith takes the chair formerly occupied by the late Dr. E. H. Trenholme. The long-expected amalgamation of the Montreal School of Medicine with Laval University is now accomplished, the necessary legislation having been secured. Dr. L. B. Durocher is to be President, and Dr. H. E. Desrosiers, Secretary, of the new Faculty. The difficulty of accommodating two sets of professors in one row of chairs has been met by the offer of a solatium of a financial character to those who by choice or necessity retire. The amount will be, according to report, four dollars per lecture hour.

A curious thing occurred recently, having a bearing on the medical education of females. McGill, it is well known, is opposed to the admission of the ladies, and at the Montreal General Hospital tickets were refused to female medical students, the influence of McGill being very strong in that corporation. At the last quarterly meeting of the governors, a motion was made to grant a clinical ticket to one of the female applicants. At once violent opposition was offered by medical and lay members of the Committee of Management, with threats of resignation, and the motion was lost. The friends of the ladies did not have long to wait, however, for in less than a week the ticket was granted. In explanation of this sudden turn about, it was admitted that danger to the subscription-list had loomed up so distinctly after the vote as to prove an effectual eye-opener. As the hospital is, in a measure, dependent on the yearly subscriptions, the wishes of the suppliers of the financial sinews cannot be ignored.

A case of much interest, alike to medical men and pharmacists, has just been before the courts. Some months ago, a French medical practitioner of the city had a case of pertussis under treatment, and decided to exhibit bisulphate of quinine. He prescribed for the patient, a young infant, one-quarter-grain doses, in powder. By inadvertence, he wrote the prescription bisulph. *morph.* The chemist, finding morphia clearly written, dispensed the only sulphate of morphia found in commerce, naturally supposing the *bi* to be a debatable chemical prefix of no therapeutic influence. The child was taken to the country, and the powders soon did their deadly work.

The physician, without having seen the child, granted a certificate of death from whooping-cough. Subsequently, another child of the family having acquired the malady, the father consulted the doctor again, and was advised to make use of the remaining powders. The administration to the second patient having produced symptoms which reminded the parents of the previous fatal case, they became alarmed, and expressed their fears to the doctor that something was wrong with the medicine. The matter was then looked into, and the real state of things discovered. The father brought suit jointly against the doctor and druggist for the death of the child. The doctor sought to lay the responsibility on the druggist, claiming that the dispensing of a *bi*sulphate for a sulphate was an improper substitution. The druggist pleaded that the dispensing of a sulphate for a non-existent bisulphate was customary, and showed in evidence that a prescription purposely written *bi*sulph. had been presented in eleven first-class pharmacies in different cities—New York and elsewhere—and in every case but one the ordinary sulphate was dispensed without hesitation; in the only one refusing, the clerk had heard of the present case, and said so.

Judge Jetté held both defendants culpable, giving judgment against the doctor for $250 damages, and against the druggist for $50. After taking counsel with other judges, he had decided that the least deviation from strict regularity in the wording should have led the druggist, previous to the dispensing of a poison, to take the extra precaution of consulting the writer of the prescription.

Some of the lessons from this sad case are obvious enough. The giving of a death-certificate without seeing the patient cannot be approved. When a prescription calling for morphia or other strong poison is presented at the dispensing-counter, the precautionary inquiry, "Is this for an adult or for an infant?" would be wise.

HOMEOPATHY.

To the Editor of THE MEDICAL NEWS,

SIR: *Re* your editorial on "The International Homeopathic Convention." Let me premise that I am a regular or rational physician, the son of a regular or rational physician, that I have subscribed for and read your periodical for nearly a quarter of a century, and am a member of the Canada and the Ontario Medical Associations. Thus much for my orthodoxy.

Several years ago exigencies of practice which it is not necessary to particularize convinced me, much against my will, that in several instances homeopathic therapeutic measures had succeeded when regular school therapeutic measures had failed. I began to investigate and test, and think that possibly my conclusions and ideas would prove of interest to some of your readers, though from the tenor of your editorial I would hardly expect them to interest you.

1. There are two distinct classes of homeopathic practitioners—the high and the low dilutionists—besides the division into educated and uneducated common to all civilized society.

2. That the high dilutionists accept and believe, or pretend to accept and believe, all the absurdities and

senseless drivel of homeopathy. They are analogous to the class in our own school who are, or pretend to be, carried away by such fads as Brown-Séquard's elixir of life. The low dilutionists are, many of them, honest, intelligent, and shrewd men that have grasped the fact of what is known as the law of similars, but have unfortunately jumped to the conclusions, that this law is universal—which is not proved, and that it is the only therapeutic law worthy of consideration—which we know to be false.

3. Homeopathy is an enormous balloon inflated by gas emitted from one or two genuine therapeutic principles, and the regular school is stupid enough to be scared by the size of the bag, at the same time trying to believe that the contained gas has no origin in fact.

4. It would be much better for medicine and humanity for the regular school to cause the balloon to collapse by boldly accepting the law of similars, the minute dose, and the dynamic power of trituration as true within the limits of proof, and adopt them as parts of our therapeutic armamentarium, instead of blindly groping for them while denying their existence, as our therapeutic leaders, Brunton, Bartholow, and Ringer, are doing.

5. That these principles are true within certain limits is demonstrable. Elaborate proof cannot be submitted here, but consider mercury alone—of which Dr. Ringer says: "It is singular how similar the phenomena produced by mercury are to those which result from syphilis." In this he merely echoes his predecessors, for years ago Stillé wrote: "Alterative medicines act in a great degree in the same direction as the diseases which they cure; mercury, for example, tends to produce lesions which bear a close resemblance to, if they are not identical with, those caused by syphilis." Thus much for the law of similars. As to the change in function and increased power produced in drugs by trituration, called by homeopaths "dynamization," consider the effect of two or three ounces of crude mercury in the alimentary canal, in connection with the effect of half a dram of the same metal triturated and exhibited—*per os*—in the form of blue mass. Call it what you please, dynamization, demonization, or what not, the increased power and change of function produced by the trituration is an entity.

6. There is absolutely no reason why any physician should not treat one patient upon the principle of the law of contraries and its necessarily large doses, and his next patient upon the principle of the law of similars and its necessarily minute doses, as may seem good in his eyes—provided always he has enough intelligence and knowledge to know which principle he is using at any given time. Instead of doing as even some leaders in therapeutics do now-a-days, who, having seen a drug succeed upon the principle of the law of similars in a minute dose, adopt it and prescribe it in large doses. See our use of pulsatilla.

7. If this straightforward course was pursued it would tend strongly to the rationalization of therapeutics and the extinction of homeopathy as a distinct school of medicine.

My positive statements are excused by my premising that they are merely *my* conclusions and ideas. Yours, etc.

Geo. M. Aylsworth.

ATMOSPHERIC CONDITIONS AND PNEUMONIA.

To the Editor of The Medical News,

Sir: On page 20 of The Medical News of July 4th is a brief editorial on "The Etiology of Croupous Pneumonia," summarizing results of the study of one hundred cases. Although this is too small a number to base conclusions upon, it seems to me probable that the conclusions (which are there tentatively suggested) are correct, because in the main they agree with those published in the *Annual Report* of the Michigan State Board of Health for the year 1886, based upon a study of very much larger numbers of cases and of deaths—namely, over 500 deaths from pneumonia in Michigan, 11,000 in the United States armies, 4000 in the European troops in India, 6000 in the native troops of India, 114,000 in London, England; nearly 1000 cases of sickness from pneumonia reported to the Collective Investigation Committee of the British Medical Association, 49,000 cases of sickness from pneumonia in the United States armies, and 31,000 weekly reports of sickness (including pneumonia when present) under the observation of the representative physicians in Michigan.

Herewith I send you a reprint of the article, in which are tables and diagrams graphically illustrating the same, showing the very close relation of pneumonia to temperature and humidity of the atmosphere, and to the daily range of atmospheric pressure (conditions mentioned in your brief editorial), and also to atmospheric ozone and to wind. In the article on "The Causation of Pneumonia," here referred to, I claimed that "the causal relation of atmospheric temperature is now established. I believe it is a general law, applicable throughout the world." Very respectfully,

Henry B. Baker.

NEWS ITEMS.

The Fiske Prize.—The Trustees of the Fiske Fund have awarded a prize of $300 to Dr. Robert W. Lovett, of Boston, for an essay on "The Etiology, Pathology and Treatment of the Diseases of the Hip-joint."

The Case of Mr. W. H. Gladstone.—As reports, more or less inaccurate, have appeared in the daily papers concerning the illness of the late Mr. W. H. Gladstone, we are glad to be able to state the actual facts. Mr. Gladstone five years ago showed the symptoms of the commencement of the growth of a cerebral tumor. These symptoms consisted in the most remarkable localized epileptiform seizures, followed by motor aphasia and paralysis of the right arm and leg. The hemiplegia and other symptoms gradually became more pronounced during the last few years. The history of the case tended to show that the growth was non-malignant, and a very prolonged course of iodide of potassium and mercury produced no amelioration in the condition. Quite recently a consultation was held between Sir Andrew Clark, Dr. Hughlings Jackson, Dr. Ferrier, Mr. Horsley, and Dr. Prickett. The result of this consultation was the opinion that an exploratory operation might be undertaken with the view of ascertaining whether the tumor could be removed, and to relieve pressure. At the same time it was pointed out that possibly it was too

deeply seated and too extensive for safe removal. On this understanding the operation was performed, but, although Mr. Gladstone recovered from the effects of the chloroform, his strength did not enable him to rally from the shock, and he slowly sank. It was found that the severe and prolonged pressure had flattened the medulla oblongata and basal structures.—*British Medical Journal*, July 11, 1891.

John Frederick Groenevelt.—The Surgeon-General of the Marine-Hospital Service has issued the following circular:

It becomes my sad duty to announce the death from yellow fever of Assistant Surgeon John F. Groenevelt, at the United States quarantine station, Chandeleur Islands, Gulf of Mexico. He was taken sick on the 18th of June, while in the active performance of quarantine duty, and died on the night of the 29th.

Assistant Surgeon Groenevelt was born in Leipzig, Germany, July 19, 1865, of American parents. On his father's side he was a descendant of Baron Arnold de Groenevelt, of Netherlands fame. His mother is a native of Louisiana. In 1878, at the age of thirteen, he entered the Tulane University, in New Orleans, and remained for seven years a student in its academic and collegiate departments, during which time he received the Greek medal, the Latin medal, the medal for mathematics, and the ancient-history medal. In 1884 he received the degree of Bachelor of Arts, and was elected president of the academic corps by the students, a place requiring tact and firmness in enforcing the discipline of the institution. In 1885 he received the degree of Master of Arts, and at once began the study of medicine under Dr. F. Loeber, of New Orleans, as preceptor. After four years of study in the medical department of Tulane University, he was graduated April 23, 1889. In 1886, while still a student, he was made interne of Touro Infirmary, and in 1887, after a competitive examination, was appointed interne in the Charity Hospital, of New Orleans, which position he filled with credit for a period of sixteen months, resigning to accept a similar position in the U. S. Marine Hospital, in the same city. Subsequently he accepted a remunerative offer as physician to a portion of the engineer force of the Mississippi River Commission, and was stationed at the Government works on the Atchafalaya River.

He was appointed Assistant Surgeon to the Marine-Hospital Service July 11, 1889, after a competitive examination, passing No. 1 in a class of twenty-six candidates.

As an officer, Assistant Surgeon Groenevelt was held in high esteem, both by those under whose immediate command he served and by the Department. His ability is illustrated by the varied and important trusts that were confided to him, and his courage by his readiness for service in the position in which he lost his life. He had shown an inclination and special aptitude for quarantine duty, and in this branch of the service his loss, for public reasons, is particularly deplored.

Personally, Dr. Groenevelt was endowed with a high sense of honor, a general culture, and scientific attainments that won for him the attachment and respect of those with whom he was brought in contact. To his bereaved father and mother, and other near relatives, I have assumed to extend the sympathy of our corps. The service has lost a young and brilliant officer, and the public an able and earnest devotee in the cause of public health.

It is hereby ordered that the flags at the Gulf quarantine station, Chandeleur Islands, be kept at half-staff and half-mast for a period of thirty days, and that the officers there on duty wear the usual badge of mourning for the same period of time.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 21 TO JULY 27, 1891.

ROBERTSON, REUBEN L., *Captain and Assistant Surgeon.*—Ordered, for duty, to Fort Niagara, N. Y., on the abandonment of Fort Abraham Lincoln, North Dakota.

KNEEDLER, WILLIAM L., *Assistant Surgeon.*—Granted leave of absence for one month.

TILTON, HENRY R., *Surgeon.*—Granted leave of absence for two months, on surgeon's certificate of disability.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 25, 1891.

FIELD, JAMES G., *Assistant Surgeon.*—Ordered to special duty in the Bureau of Medicine and Surgery.

HOPE, JAMES S., *Assistant Surgeon.*—Ordered to the Receiving-ship "Franklin."

MORRIS, LEWIS, *Assistant Surgeon.*—Ordered to the "Ajax" and other monitors, Richmond, Va.

KEENEY, JAMES F., *Assistant Surgeon.*—Promoted to Passed Assistant Surgeon.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING JULY 18, 1891.

MURRAY, R. P., *Surgeon.*—To proceed to Gulf Quarantine, for temporary duty, July 1, 1891.

SAWTELLE, H. W., *Surgeon.*—Relieved from duty at Portland, Me.; ordered to Boston, Mass., July 11, 1891.

IRWIN, FAIRFAX, *Surgeon.*—When relieved at Boston, Mass., to proceed to Buffalo, N. Y., for temporary duty, July 11, 1891.

CARTER, H. R., *Passed Assistant Surgeon.*—Ordered to Washington, D. C., for temporary duty, July 2, 1891.

PECKHAM, C. T., *Passed Assistant Surgeon.*—Granted leave of absence for seven days, June 30, 1891.

DEVAN, S. C., *Passed Assistant Surgeon.*—When relieved at Buffalo, N. Y., to proceed to Portland, Me., for duty, July 11, 1891.

BROOKS, S. D., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days. July 13, 1891.

KINYOUN, J. J., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, July 14, 1891.

HOUGHTON, E. R., *Assistant Surgeon.*—To proceed to Cleveland, Ohio, for temporary duty, July 8, 1891.

DEATH.

GROENEVELT, J. F., *Assistant Surgeon.*—Died of yellow fever, at the Gulf Quarantine Station, June 29, 1891.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. THE OPERATIVE TREATMENT OF SOME DISEASES AND INJURIES OF THE NERVES.[1]

BY JOHN B. DEAVER, M.D.,

ASSISTANT PROFESSOR OF APPLIED ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA; PROFESSOR OF SURGERY IN THE PHILADELPHIA POLYCLINIC.

WHEN so much is written on modern operative procedures it is well not to overlook conditions that in many instances are at least quite as important for the welfare of the patient as some of those that, in the past few years, have excited much discussion. I shall briefly report some cases of certain diseases and injuries of the nerves that I have operated upon, with a few remarks on the operative treatment. This class of affections is common enough to interest both the physician and the surgeon, and is of sufficient practical value to warrant me in presenting a few thoughts for discussion.

The most important of the diseases of the nerves for the relief of which operative treatment may be resorted to are:

1. Painful affections, including neuralgia, neuritis, and neuromata.
2. Local spasmodic affections, including such diseases as spasmodic torticollis, facial tic, tetany and athetosis.
3. Chronic contractures, including those the result of old traumatisms and those due to hysteria.
4. Scleroses.

PAINFUL AFFECTIONS OF NERVES.

Neuralgia.—In studying neuralgia from a surgical as well as from a medical standpoint, it is important not to lose sight of its predisposing and exciting causes. Cases traceable to known exciting causes, such as injury of a nerve, or pressure upon or irritation of nerve trunks, and such peripheral irritation as is present when the end of a nerve becomes involved in a cicatrix, offer the best outlook for operative interference. The so-called epileptiform neuralgia, which almost invariably attacks the face and involves any one or all of the three branches of the fifth nerve, is also favorable for operative treatment. This form of neuralgia consists of two main varieties, one in which the pain is accompanied by twitching of the facial muscles, and a second in which pain is the only pronounced symptom. In this form of neuralgia the pain is paroxysmal, and may be occasioned by an attempt to swallow liquid, by a breath of cold air, etc. The three cases of excision of the superior maxillary nerve included in my list were of this variety. In one of these the slightest irritation of the lip, the nose, or the lower eyelid of the affected side would bring on a severe paroxysm of pain. Many cases formerly recognized as neuralgia are now generally believed to be neuritis, but a disease generally known as neuralgia remains. How does operation do good in neuralgia? It is probable that in this affection, as in locomotor ataxia, the pains may sometimes be due to molecular disturbance or impaired nutrition of the nerves themselves, or of the posterior root zones or posterior horns of the cord. Operation probably changes the molecular arrangement of the nerves and nerve-centers and stimulates nutrition.

Neuritis.—In neuritis, according to the stage, we have a more or less high or low grade of inflammatory process. In the chronic stage of many cases the inflammation has practically subsided, and left an exudate and adhesions, the nerve having secondarily degenerated. Operation is useful in two or three ways, either by allowing the nerve a better chance to repair, by opening the sheath and breaking up any adhesions that may be present; or, when degenerated, by disturbing the molecular condition of the nerve and stimulating it to take on regenerative action; or again, in those cases of chronic inflammation of a nerve in which physiological movements never allow it to be sufficiently long at rest to accomplish a cure, by removing a section of the inflamed nerve, and thus getting rid of the constant irritation.

Neuromata.—Neuromata are tumors occurring in connection with a nerve-trunk. They consist of two main classes, the true and the false. A true neuroma is composed entirely of nerve-filaments. This variety is very rare, some authorities even doubting its existence. False neuromata situated on or in a nerve are fibrous or fibro-cellular growths; a few also contain cysts. They are movable, but only transversely. They may occur in the continuity of a nerve, but particularly at its cut extremity, as seen in stumps. They are usually not painful, except when exposed to pressure, or so situated that ordinary physiological acts cause irritation. They are some-

[1] Read before the Lancaster County Medical Society, July 1, 1891.

times met with in large numbers. When found in the continuity of a nerve, they call for removal, which should be done with as great care as possible so as to avoid dividing the nerve. Should division of the nerve be required for the complete removal of the growth, the ends should be immediately approximated by suture. When met with in stumps, removal, if feasible, is also to be practised, and when not feasible re-amputation offers the only alternative. Nerve-stretching is advised in some cases prior to complete removal; in my hands this procedure has not proved successful. There is a variety of neuromata known as plexiform. Of this class I have met with one case, the report of which is included in my list of cases. Bowlby describes these tumors as being made up partly of soft connective tissue and fat, imbedded in which are medullated nerve-fibers and white fibrous tissue. A microscopical study of the case that I removed showed it to be made up of connective, adipose and white fibrous tissue and medullary nerve-fiber—corresponding, therefore, with Bowlby's description. The growth was very slow in forming, having been present a number of years before it came under observation. It is now five years since it was removed, and recurrence has not taken place.

LOCAL SPASMODIC AFFECTIONS OF NERVES.

Torticollis.—I have had several cases of operation on the spinal accessory nerve, and I believe that some of the reasons for the frequent failure in these operations are, first, because the movements involved in the spasm are the resultant of the action of various muscles which have diverse nerve-supplies; secondly, because the spasm is sometimes due to irritation reflected from sensory nerve-areas to the motor nerve—as, for instance, from the major or minor occipital to the spinal accessory; thirdly, in a few cases at least, because the spasm is due to a lesion of cortical or other encephalic centers.

Facial Tic.—In cases of facial tic, or so-called histrionic spasm, in which the muscles supplied by the facial nerve are affected, the operation of nerve-stretching has been performed a great many times, but most of the cases have been failures or only temporarily successful, for the simple reason that the vast majority of cases are due either to degenerative lesion of the facial nucleus or to cerebral irritation or degeneration.

Tetany.—In cases of tetany, nerve-stretching may for a time arrest the tremor and twitchings associated with the spastic contractions, but the operation is not usually to be advised.

Athetosis.—Nerve-stretching in the treatment of athetosis has not been of much avail, causing only temporary cessation of the clonic spasms and a paretic condition of the affected part. When the paresis passes off, the tremor and spasm return. Evidently the majority of such cases cannot be permanent successes, since the source of the spasm or tremor is a persisting central lesion, usually situated in the cortex or near the thalamus in the interior of the brain.

CHRONIC CONTRACTURES OF NERVES.

In cases of chronic contracture of nerves the result of old traumatism, benefit from the operation is dependent upon the relief of the chronic neuritis and the loosening of the attachments present. In hysterical contractures operation may afford relief, but these cases are quite as amenable to treatment much less radical in character. In these cases, if the operation of nerve-stretching does good at all, it is by acting on the spinal centers, or by mental impression.

SCLEROSES.

The usual temporary effect of nerve-stretching in the treatment of lateral sclerosis is that the spastic condition of the muscles is partially overcome, the tingling in the extremities disappears, locomotion is improved and the reflexes are not changed. The benefit is not permanent either in this affection or in posterior sclerosis. Failures have sometimes followed this operation, owing to incomplete measures having been adopted, the nerve having merely been exposed and returned to its original position.

Nerve-stretching, as an operative procedure, has had rather a limited range of application. The benefit resulting from its performance has been thoroughly discussed without any definite conclusion as to the manner in which the result is obtained having been arrived at.

Pathological researches have been conflicting and of no practical value, hence the neurologist and surgeon are justified in acquiring actual experience by means of clinical experimentation in other affections than those which have in the past been recognized as fit subjects.

NERVE-INJURIES.

The most common form of nerve-injury for which the surgeon is called upon to operate is division. The complication formerly feared, and which, therefore, deterred surgeons from approximating the cut ends of the nerve by suture, was tetanus. Since the days of antiseptic surgery this complication is no longer feared. It is now a proved and acknowledged fact that the origin of tetanus is microbic, hence the use of antiseptics prevents infection and lessens very materially the chances of this complication arising. There is no doubt that the ends of a divided nerve, if left to themselves, sometimes unite. But this does not offer

an argument against suture, and I therefore take it for granted that every surgeon would unhesitatingly use the suture. The operations for the suture of divided nerves are primary and secondary. Primary suture is stitching together the ends of a divided nerve immediately after the injury or within a short time afterward and before healing of the wound has commenced. Some surgeons believe that when the section is clean, with but little separation and not complicated by an extensive wound of the neighboring soft parts, suturing should not be practised; but with these I cannot agree, for if it is a justifiable procedure under reverse conditions, it is all the more indicated when it is most likely to be followed by success. One or more sutures, depending upon the size of the divided nerve or nerves, are to be passed through the trunk, neurilemma and tubules inclusive, a short distance from either end, and drawn tight, making apposition perfect. The suturing completed and the wound closed, the limb is to be placed and fixed in a position favoring relaxation of the injured nerve. I prefer the aseptic silk suture, believing this in the long run to be most reliable. What disposition is to be made of either end or both ends if found to be much lacerated and contused? The answer to this is that if the contused and lacerated nerve-tissue is believed to be devitalized, it should be removed before the suture or sutures are introduced.

Both the proximal and the distal ends are then to be stretched, when, if apposition cannot be effected without too great resulting flexion, recourse may be had to one of the following means: *a*. Split the cut end of the nerve in such a way that by drawing down the section from the proximal end it can be united to the section turned up from the distal end. *b*. Unite the distal end of the divided nerve to a neighboring nerve. *c*. Implant a section of nerve taken from an amputated limb or from a lower animal. *d*. It has been suggested to connect the divided ends of the nerve with strands of catgut; also to introduce a decalcified bone tube between the ends of the nerve, on the supposition that nerve-tissue will be prolonged along the strands of gut or into the caliber of the tube. This latter means furnishes a framework on which the granulations can spread.

Should primary suture fail to bring about complete restoration of the part, another operation consists either in freeing the nerve, if confined by scar-tissue, or of secondary suture. Secondary suture, of which I report one case, is not by any means so simple a procedure as primary suture. The first difficulty is in finding the distal end of the nerve. This is best accomplished by making a careful dissection, the limb having been rendered bloodless. If there be trouble in finding the distal end, the nerve below the section should be exposed, as suggested by Bowlby, when it can be traced to the scar. The ends of the nerve having been exposed, the next step in the operation consists in making a section of them. The proximal end, if found to be bulbous, is to be divided near the junction of the bulb with the trunk; the distal end, if found bulbous, is to be treated in the same manner as in the case I report. If the distal end is found not to be bulbous, but atrophied, the usual condition met with, a very small section is removed. The next step is to determine whether or not the ends can be brought into apposition. If not, they are to be treated in the manner spoken of under the head of primary suture. The length of time required for restoration after primary suture is usually short, but after secondary suture it is problematical and often quite long.

Report of Cases.—To illustrate my remarks, I have selected sixteen cases from those upon which I have operated. Of this number there were six of trifacial neuralgia, in three of which I removed the entire superior maxillary branch, in one the entire inferior dental branch, and in two a portion of the inferior dental branch; one of stretching the posterior tibial for obstinate plantar neuritis; two of stretching the sciatic for neuralgia; one, for neuritis, of excision of a portion of the long saphenous, immediately after its exit from Hunter's canal; one of excision of the greater portion of the supra-trochlear, also for neuritis; one of ligation of the spinal accessory upon two consecutive occasions for spasmodic torticollis; one of freeing the musculo-spiral from encroaching callus; one of stretching the median for tetany; one of removal of a plexiform neuroma; and one of secondary suture of the external popliteal (peroneal).

Case I. *Complete Removal of the Superior Maxillary Branch of the Trifacial.*—Mrs. S., aged forty-eight, was a patient of Dr. H. C. Clark, of Woodbury, N. J. The history of the case is, in short, that she had for seventeen years suffered with trifacial neuralgia, during all of which time, to obtain any relief, she was required to take morphia, and latterly in very large and repeated doses. She had been given the benefit of all doubt in the way of internal and local treatment, both by Dr. Clark himself and by noted neurologists throughout the country. More than two years ago I removed the nerve in question, doing Carnochan's operation, which I prefer. Complete and permanent relief followed the operation. At present writing, June 23, 1891, there has been no recurrence.

Case II.—The patient was referred to me by Dr. C. K. Mills. He was a man aged seventy-five years, a letter-carrier, and therefore exposed to all kinds of weather. Several years before he came under Dr. Mills's care he began to suffer with severe pain in the side of the face beneath and above the eye, and

sometimes in front of the ear. The history of the case was the usual one of a gradually augmenting trigeminal neuralgia. Many remedies were used by various physicians. He had also been operated on twice by two different surgeons. At the time the patient was placed under my care the attacks were practically continuous. I removed the superior maxillary branch of the fifth nerve, giving the patient permanent relief.

CASE III.—The history of this patient—Mrs. M., aged fifty-four years, a patient of Dr. H. A. Smith, of Philadelphia—is almost parallel with that of Case I. The neuralgia was of seventeen years' standing. Removal of the superior maxillary nerve was followed by relief.

CASE IV. *Removal of the Inferior Dental Branch of the Trifacial.*—T. M., aged fifty-four years, a farmer, suffering from neuralgia of the right inferior dental nerve, was admitted into the surgical wards of the German Hospital December 16, 1889. The history of the case showed it to be one of long standing, and one in which an unsuccessful operation had been done one year before coming under my care. I removed the entire inferior dental nerve. The portion occupying the canal was exposed and taken out by chiselling away the outer wall. Immediate relief followed the operation, and at the present time the patient, through his sister, informs me that he is perfectly well.

CASE V.—J. H., aged thirty-seven years, housekeeper, was admitted into the surgical wards of St. Mary's Hospital February 13, 1891, with a history of severe neuralgia located in the region of the inferior maxilla. The pain, which was paroxysmal, extended from the ramus of the left inferior maxilla to the chin. These seizures lasted from two to three hours, and occurred three or four times daily. Hot or cold liquids, or solid food, taken into the mouth brought on severe paroxysms. The teeth on the affected side had been removed, without relief. A portion of the inferior maxillary nerve had been excised, with temporary relief; the trouble returned, and her suffering was almost unbearable. A second operation was performed, which consisted in trephining the ramus of the lower jaw at the point of entrance of the inferior dental nerve. The opening was enlarged upward, and the nerve traced to its origin from the inferior maxillary. The outer wall of the dental canal was then chiselled away as far as the site of the old operation, where the nerve was found fixed by fibrous and connective tissue containing nerve-fibers. The exposed nerve was then removed.

CASE VI.—A. M., aged thirty-three years, a housewife, was admitted into the wards of the German Hospital August 1, 1890, suffering from pain, paroxysmal in character, referred along the course of the inferior dental nerve. She had suffered for a long time, and had received a thorough course of treatment without affording relief. A portion of the nerve was removed, with complete relief from pain.

CASE VII. *Excision of the Long Saphenous Nerve.*—C. K., aged fifty years, a tinsmith, was admitted to the surgical ward of the German Hospital, December 9, 1890, suffering from unmistakable chronic neuritis of the long saphenous nerve supplying the inner side of the knee and leg. The nerve was exposed immediately after its exit from Hunter's canal, and a section of two inches removed. The recovery was perfect.

In circumscribed plantar neuritis, when the pain is confined to the third metatarso-phalangeal articulation, or more particularly to the fourth, the ingenious operation of Dr. Thomas G. Morton, of Philadelphia, that of excision of the articulation, often serves to accomplish a cure. In cases of this character, however, I cannot but think that excision of the affected plantar nerve or nerves would accomplish all that is accomplished by the removal of the joint. This excision of the nerve or nerves must be done radically, taking them out as far back as possible, and not being satisfied with removing a section, say of only one inch in length, which would afford but temporary relief.

The rationale of the operation as suggested by Mr. Collier is, that as the disease consists essentially of an excessive intermittent and irregular discharge of energy along the spinal accessory nerve, the introduction of increased resistance in the course of the nerve and the possible deflection of some of this energy into other structures than the sterno-mastoid and trapezius muscles might result in an abatement or cure of the trouble. Mr. Collier has reported one successful case. Temporary improvement followed the operation in the case I report, but I am sorry to say it was but temporary, as in a short time the spasms returned with their former severity. Thinking perhaps the technique of my operation was faulty, I repeated it, but with a negative result. Of the different operations performed for the relief of this condition, namely, stretching, excision, and ligation of the spinal accessory nerve, also myotomy of the muscles at fault, and also the operation devised by Dr. W. W. Keen—division of the cervical nerves supplying the posterior cervical rotators—that of ligation strikes me as the most philosophical. It is questionable, however, if spasmodic torticollis can be permanently cured by operative treatment alone, unless the centers governing the movements of the muscles affected can be definitely located and successfully removed. Even were this result attainable, recurrence of the spasms would be as likely to follow as in other cases of focal (Jacksonian) epilepsy, after the removal of a portion of the cortex.

CASE VIII. *Excision of the Supra-trochlear Nerve.*—The patient, a lady, was seen by me in consultation with Dr. O. P. Rex, of Philadelphia. She was suffering from obstinate facial neuralgia, limited to the distribution of the supra-trochlear. The ordinary line of treatment failing to afford relief, the nerve

in question was removed. There was complete recovery.

Case IX. *Plexiform Neuroma.* — W. H. P., twenty-nine years old, a hatter, was referred to me by Dr. Jno. Strobel, of Philadelphia, giving the following history: For eleven years he had had over the olecranon process a growth which had become of the size of a large English walnut; the overlying skin was dark-bluish in color. The patient had for six years worn an appliance to prevent movement of the elbow, and to protect the growth from the clothing, it being so sensitive that the slightest irritation would suffice to excite unbearable pain. So great, indeed, was the pain caused by the slightest interference with the growth, that the patient would not permit me at the first visit to examine it. I believed it to be a neuroma and advised its removal. The operation was performed in December, 1889. Recovery was prompt and satisfactory.

Case X. *Removal of Callus Encroaching upon the Musculo-spiral Nerve.*—The patient was a man, thirty-five years old, who had sustained a fracture of the upper portion of the shaft of the right humerus, the healing of which resulted in exuberant callus, involving the musculo-spiral nerve. When he came under my notice there were present all the symptoms of neuritis of the radial and posterior interosseous nerves, the terminal branches of the musculo-spiral. Recognizing the cause of the condition, I advised removal of the offending callus. The operation was done, and followed by cure.

Case XI. *Stretching of the Posterior Tibial for Neuritis.*—A. K., aged thirty-eight years, a seamstress, was three years ago admitted to the Philadelphia Hospital, in the service of Dr. C. K. Mills. She had been a drinking woman, and for several years had been subject to epileptic seizures. For ten months she had suffered from pain in the left foot, chiefly in the heel and along the outer border of the foot. The pain was accompanied by a "pins-and-needles" sensation. It was dull and aching in character. A few weeks before the commencement of the trouble in the left foot, a similar, but more severe, pain was felt in the right foot, chiefly in the heel and along the outer border. Not receiving any relief from well-directed remedies used both internally and locally, Dr. Mills asked me to stretch the right posterior tibial nerve, which I did on June 11, 1887. The nerve was exposed between the internal malleolus and the tuberosity of the os calcis. The patient was kept in bed for six weeks after the operation; recovery followed.

Case XII. *Stretching of the Median Nerve for Tetany.*—The patient, a man, twenty-eight years old, was admitted to the surgical ward of the Philadelphia Hospital, in the summer of 1888, with spasmodic contraction of the superficial flexors of the forearm (those supplied by the median nerve). Both by the neurologist on duty and myself the trouble was regarded as tetany. Therapeutic agents indicated in this condition having been tried with negative results, I stretched the median nerve. Although not resulting in absolute cure the operation was followed by marked improvement. The patient left the institution contrary to advice and I am consequently unable to record the further history of the case.

Case XIII. *Successful Stretching of the Sciatic Nerve.*—This patient, referred to me for operation by Dr. Mills, was an electrotyper, thirty-two years of age, without a history of syphilis, constitutional disease or abuse. About three years before he came under observation, he was in the habit of frequently riding the bicycle, particularly in the evenings. Three months after beginning this exercise, he noticed pain in the back of the left thigh. This persisted from day to day, and from week to week, gradually increasing in intensity. The pain seemed to start about half-way between the hip and the knee in the back of the thigh. From this point it would extend in both directions, so that the painful and uncomfortable sensation would reach the bottom of the foot, and in the other direction, the sacral region. At times he would have considerable numbness and tingling in the leg, particularly below the main focus of pain. He described the pain as at times being excruciating. For three years he had been treated by various physicians. Among other measures that were thoroughly tried were electricity, both faradism and galvanism, the actual cautery, and many internal remedies, such as iodide, the salicylates and antiperiodics, as arsenic, quinia, etc., also numerous anodynes. A course of massage and Swedish movements had also been tried, and he had been subjected to hypodermatic injections.

He suffered mostly with this pain in the evening, and when sitting down during the day. When moving about, the pain gradually decreased, and he was sometimes hardly aware of it, but it never absolutely left him. We found that the pain was still most severe at the original spot, about the middle of the posterior thigh; some numbness and tingling followed the posterior external aspect of the leg, downward to the foot. Lately it seemed as if the pain had increased in the upper thigh and in the gluteal region. On pressure no tenderness was present. We also made a careful examination by the rectum to ascertain the condition of the sacral plexuses, and determine whether or not a growth or other morbid condition was present in the pelvis, but nothing was discovered. As the patient had already been treated by almost every measure promising success, except nerve-stretching, this was advised, and, after having the operation explained to him, he consented to have it done. With strict antiseptic precautions, I exposed the nerve for several inches at the place of the greatest pain. No tumor could be detected. Some thickening and inflammation of the nerve-sheath was present for about an inch and one-half or two inches. After opening the sheath and loosening the thickened bands, the nerve was carefully stretched by pulling it strongly first in one direction and then in the other. In about two weeks the man was again on his feet. For several weeks he presented symptoms of traumatic neuritis in the sciatic distribution below the seat of the operation—spontaneous pain and hyperesthesia in the nerve-distribution, and pain on lateral squeezing of the foot—but the old pain was gone. After a few weeks of

treatment with mercurial and belladonna ointments, salicylates, tonics, rest and hot applications, the neuritis which had resulted from the operation disappeared. He was also free from the old pain, and has remained so to the time of making this report.

CASE XIV.—T. J., aged twenty-five, a laborer, a patient in the nervous wards of the Philadelphia Hospital; had been irregular in his habits, and was addicted to the use of alcohol—drinking, according to his own statement, "everything that came in his way." He had never had syphilis. In February, 1890, he complained of soreness of the hip and thigh. This soreness increased over the back of the leg and thigh, and in the upper portion of the foot; he also had a tingling and a numbness in the lower part of the leg and foot. These were greatly increased by exertion or pressure. Lying in bed greatly relieved him, and, in consequence, for the sake of the comfort that he obtained he often remained in bed two or three days at a time. In walking, semi-flexion of the leg apparently relieved the intense pain. Latterly this pain had extended to the gluteal regions. He was treated for several months with the usual remedies that are employed in sciatic neuritis, including iodide, antiperiodics, salicylates and hypodermatic injections of morphine and atropine. He improved somewhat, but no decided relief was obtained. September 3, 1890, he was removed to the surgical wards of the hospital, where I exposed and stretched both sciatic nerves. At first he had some of the same neuritic discomfort that followed the other operation, but after a week he began to improve decidedly. In less than a month he was entirely free from pain in the leg and thigh.

CASE XV. *Ligation of the Spinal Accessory Nerve for Relief of Spasmodic Torticollis.*—The patient was a woman who some months before had sustained an injury to the back of the head. The resulting clonic torticollis was of a severe nature, resisting all ordinary treatment, both internal and external. Gelsemium had been tried with apparent success, but on discontinuing the drug there was an immediate return of all previous symptoms. More radical measures being evidently necessary, Dr. C. K. Mills, under whose care the patient was, suggested to me the propriety of ligating the spinal accessory nerve of the affected side with silver wire, after the manner of Mr. Mayo Collier, of London. The nerve was exposed at its exit from the sterno-mastoid muscle, and ligated as high up as possible. The loop of wire an inch in length was left at the bottom of the wound, where it subsequently became encysted. The wound healed kindly, the wire ligature occasioning no inconvenience.

CASE XVI. *Secondary Suture of the External Popliteal Nerve.*—Mr. M., when twenty years of age, at the battle of Sharpsburg, in 1862, sustained a gunshot injury of the great trochanter of the right side, followed immediately by intense pain, causing him to fall to the ground. Upon rising and attempting to put the right foot to the ground he was again attacked with pain. Ten days later, when turned over on the left side to have the wound dressed, he suffered from pain referred to the outer side of the knee. Four months from the time of the injury, he resumed his duties in the army, being but little inconvenienced by the wound. In 1867 (five years after injury), he noticed on the outer side of the right knee a small lump, pressure upon which caused pain referred along the course of the external popliteal nerve. The swelling slowly increased in size and sensitiveness until it was about the size of a small English walnut. In April, 1890, the lump, evidently a neuroma (it was not examined microscopically), was removed by his family physician, no anesthetic being used. The removal was followed by paralysis of the extensor muscles of the foot, which indicated that the nerve had been severed in excising the growth. He consulted Dr. William Pepper, of Philadelphia, who, after a careful examination, referred him to me for my opinion as to the advisability of an operation. In view of a number of successful results obtained by secondary suture of nerves of the upper extremity, it seemed reasonable to suppose that the operation might be equally successful in the lower extremity, although no case had as yet been reported. I operated upon the patient at his home, July 1, 1890. Upon making an incision in the line of the nerve, the two ends were exposed. Both were found bulbous, which is contrary to the usual condition in such cases, the lower end being commonly frayed out and lost in the surrounding tissues. The bulbous ends were freshened by the removal of a small section, approximated by stretching and flexion of the leg upon the thigh, and held in apposition by catgut and aseptic silk sutures. The flexed position of the limb was maintained by the application of an obtuse internal angular splint worn for six weeks. At this time the splint was replaced by a plaster-of-Paris dressing. Barring an attack of traumatic neuritis the recovery was uneventful. Some months after the operation, at my suggestion he came to Philadelphia and was placed under the care of Dr. C. K. Mills for massage and electrical treatment. Examination showed a return of sensation, but not of motion.. The nerve was undoubtedly united, it being distinctly felt in its normal position, and pressure at the seat of suture causing pain along its terminal branches, which before the operation had become so degenerated that sensation was abolished. The patient has recently written to me that he is slowly regaining the power of motion, which is a further proof of good union. In cases reported by Bowlby, motion has rarely returned earlier than fifteen months after operation. This is the only recorded case of secondary suture of the external popliteal nerve—at least I have been unable to find any other.

HEAT-STROKE (THERMIC FEVER) IN INFANTS.

BY H. ILLOWAY, M.D.,
LECTURER ON DISEASES OF CHILDREN, CINCINNATI COLLEGE OF MEDICINE AND SURGERY.

HEAT-STROKE, as an effect of atmospheric heat, has as yet no place in the treatises on pediatrics. Clinical facts that have come under my observation have convinced me that as an etiological factor summer heat deserves greater consideration than it has

hitherto received and that heat-stroke is one of the pathological states that may be produced by it.

Case I.—On a September morning I was called to a baby, one year old, in good flesh, that nursed at the breast. The afternoon of the previous day it had been seized with vomiting and diarrhea; the family physician was called and prescribed neutral mixture, 2 ounces; laudanum, 12 drops. Of this mixture a teaspoonful was given every two hours, until the patient had taken about half. When I saw the patient, the pulse was feeble—almost imperceptible; the eyes covered with a film; the respiration gasping and shallow; the muscles of the jaw firmly contracted; the occiput and the whole body hot to the hand. The face was purplish and presented the appearance of a person in asphyxia. I directed an ice-bag to be placed on the head and flannel cloths wrung out of hot mustard-water to be applied to the feet. Two teaspoonfuls of a mixture of three parts water and one part whiskey were given with a few grains of hydrate of chloral. A few hours later the child was no better. As the child did not swallow, the medicine was not taken. The thermometer in the axilla indicated 106° F.; the skin was dry and hot, the respiration was shallow and infrequent. There was complete loss of consciousness. I had the child placed in a warm bath, the ice-bag being kept upon the head. For the time being, this seemed to do good, but after the child was out of the bath for a few moments it relapsed into its former condition. I therefore had the naked child wrapped in a sheet wrung out of cold cistern water (having a temperature of about 70°), and placed in its cradle and covered with a blanket; in seven minutes the sheet was hot and almost dry; it was removed and replaced by a fresh one. The respiration became deeper and more regular and the child presented the appearance of being in a tranquil sleep. The moment the sheet became warm, the baby grew restless and would groan, the respiration becoming gasping, to be relieved by the application of a freshly wrung-out sheet. The application of the wet pack was continued all the afternoon and night. At 11 P.M. the thermometer recorded 103° F. The sheets would now remain cool for half an hour. This procedure was continued regularly all night, the mother doing her duty attentively and intelligently. The next day, at 8 A.M., the thermometer in the axilla registered 101° F. The child still appeared unconscious. The treatment was continued. At 1 P.M. the child's temperature was 99¾°. At 4 P.M. consciousness returned. The wet pack was now discarded and the treatment continued with quinine in small doses, and strong coffee. The child was discharged well.

Case II.—In June I was called to see baby V., ten months old, well developed and in fair flesh; it nursed at the breast. It was taken ill in the night with vomiting and diarrhea. At the time of my visit, at 10 A.M., the baby was lying in the cradle with its eyes half closed, moaning occasionally, and restless. The temperature in the axilla was 104° F. The child vomited whenever she nursed. I prescribed a mixture of spirit of Mindererus, sweet spirit of niter, and a minute quantity of tincture of aconite, to be administered every hour. In the afternoon I was told by the mother that the child had vomited the medicine every time it was administered; the child also vomited after nursing. The temperature appeared higher. I directed the mother to omit the medicine for a few hours and not nurse it during that time; at intervals to sponge it with lukewarm water and vinegar. About 9 P.M. the temperature of the air, which had been high all day, had become intense. The temperature of the baby, despite repeated spongings, had risen to 105¾° F. There were great heat of head, great restlessness, hurried respiration, marked movement of the alæ nasi, and rapid pulse. I directed that the child be placed in a cold wet pack. The effect was marked; the restlessness disappeared at once, the respiration became tranquil and the child fell into a calm sleep. As soon as the pack became warm, the restlessness and hurried respiration returned, to disappear immediately upon the renewal of the pack, which was continued all night. At 9 A.M. the temperature in axilla was 101½° F. The baby had nursed twice in the night and had retained the milk. The diarrhea had ceased. The wet cloths were continued until noon. At 1 P.M. the temperature was normal, and the pack was discontinued. There was no return of the unfavorable manifestations. The child was discharged as well the next morning.

The two cases reported are undoubtedly cases of *heat-stroke* or *thermic fever*, recognized by a consideration of the symptomatology and comparison with the phenomena obtained in experimental investigations, and by the success of the therapeutic measures adopted. In experimental studies upon the effects of high temperatures in animals, a series of phenomena, progressively manifesting themselves as the temperature of the animals rose, was observed. These may be summed up in the order of their appearance: nausea; dyspnea and cardiac irregularity, with greatly increased rapidity of pulse; and heat rigidity. In the experiments made by Krishaber[1] upon himself he noted as a consequence of the rapid elevation of temperature: increased rapidity of heart's action (pulse rising from 75 to 160), headache, malaise, and nausea—phenomena like those observed in the experimental studies on animals. That the first case is one of heat-stroke will hardly be questioned, the array of symptoms pointing to this conclusion. We have the initiatory phenomena, the progression in gravity, until at the time when I saw the case the climax was reached; a state of asphyxia, due to the diminished exhalation of carbon dioxide and great destruction of oxygen, an effect observed by Litten in his experimental

[1] Litten: "Ueber die Einwirkung erhöhter Temperaturen auf den thierischen Organismus," Virchow's Archiv, Band 70; Naunyn: "Fieber und Kaltwasserbehandlung," Archiv für experiment. Patholog. u. Pharmacol., Band 18.

studies. In addition we note the occurrence of heat-rigidity in a limited number of muscles. The second case, although not so marked as the first, is, nevertheless, also one of heat-stroke. In this case we note the increase in the gravity of the phenomena running parallel with the exaltation of the temperature. We have the vomiting that ensued when anything was administered by the mouth or when the patient nursed; then the setting in of dyspnea, with the frequency of the respirations; the great rapidity of the heart's action, as indicated by the pulse; the great restlessness, due partly to the dyspnea and partly to the cerebral irritation, equivalent in the infant to the headache observed in the experimental study in adults. Taking both cases together, we have a striking clinical verification of the phenomena noted in the experimental studies, the second case presenting the phenomena as they gradually develop, and the first illustrating the climax.

Two symptoms recorded in the history of our cases, vomiting and diarrhea, are as yet unaccounted for, similar phenomena not being recorded in the experimental studies referred to. A moment's thought, however, will show that they have the same etiological relation as the other phenomena and that they form part of the history of heat-stroke. Nausea is a manifestation of high temperature; it is a short step from nausea to vomiting, especially in the infant that cannot speak and to whom food is tendered at varying intervals. As a result the food is immediately rejected. It is indeed so common a fact that infants vomit with any sudden and marked elevation of temperature that this point needs no further elucidation here. There is, however, further and more direct proof in the fact that in adults vomiting has been noted as one of the phenomena of heat-stroke.[1]

It is an established fact that with a febrile elevation of temperature the digestive power of the stomach is greatly depressed; this is especially true in the pathological state known as heat-stroke, in which even minor degrees of elevation of temperature provoke greater disturbances than the more marked elevations of fevers.[2] Part of the food in the infant's stomach passing undigested into the intestinal canal, there acts as an irritant, excites abnormal peristaltic movement and a diarrheal discharge results. In this connection another factor may be invoked, namely, stimulation of the vagus center. It has been experimentally demonstrated by Cyon that a sudden elevation of the temperature of the blood circulating in the brain (from 34 to 48° C.), by stimulation of the vagus center in the medulla,[3] causes slowing of the heart's action (from 23 to 5 in ten seconds).

The increased frequency of respiration observed with elevations of temperature, is also confirmatory of stimulation of the vagus center. It is probable that moderate elevation of temperature will have a more decided effect upon the very mobile and impressionable nervous system of the infant than in the case of an adult. It is well known that stimulation of the vagus excites peristaltic movements in the small intestines.[1] Now this stimulation of the vagus, alone or superadded to the irritation produced by undigested food, excites such rapid peristalsis as to give to the evacuations their diarrheal character. Taking the foregoing facts into consideration we are justified in considering the vomiting and diarrhea mentioned in the histories of the cases related as part of the symptomatology of heat-stroke.

CASE III. In the summer of 1885, I was called one night, at about 10 P.M., to see baby K., about one year old, bottle-fed. The family lived in a long one-story building, the front and larger part of which was used as a furniture store and the remainder as the living-rooms. The building was closed in on both sides and all the ventilation and fresh air was provided for by the front doors. During the afternoon the infant had been seized with vomiting, rejecting all that was given him. Later, he became restless, and would not lie in his cradle. It was a warm night. After a hasty examination I prescribed a mixture containing hydrate of chloral. The medicine was rejected each time it was administered. The child passed a restless night. On more careful examination it was found that as the child was held on its mother's arm it inclined its head toward the head and shoulder of the mother, as if its head were heavy and difficult to support. The head was hot to the touch; the eyes were dull; the face was pale; the axillary temperature was 103°; the pulse was about 130. Taking all the phenomena into consideration I concluded that I had a case of incipient brain trouble before me. It, however, occurred to me that perhaps the heat of the room might be responsible for the illness of the child. I therefore directed that cloths wrung out of ice-water be applied to the child's head and that after a few hours' steady application of the cold cloths upon the head, it be given every half-hour a teaspoonful of a mixture of equal parts of lime-water and milk; if this were well borne, then after four or five hours the dose was to be increased to two teaspoonfuls. On the next morning I found my little patient much better. The child appeared brighter, it held its head better, it did not vomit and had rested well during the night. The temperature was 101°, the pulse was much diminished in frequency. I directed the treatment to be continued, advised a slight increase in the quantity of milk and lime-water, but

[1] Foster's Physiology, ed. 1880, p. 380.

positively forbade feeding with the bottle. On the following morning my patient was well, but weak. The baby had slept well during the night; in the morning it had taken its bottle well and with some avidity. Its temperature was normal and it held its head up well.

At the first glance it might appear that I had incorporated into this paper a case of beginning meningitis. It needs no elaborate elucidation, however, to demonstrate clearly that this is not so, and that the case properly belongs in the category under consideration. There was no prodromal history. The child was well until the day upon which I made my first visit. There is no history of convulsions, no history of twitching. There were no ocular phenomena, nor any drowsiness. In fact most of the symptoms of meningitis were wanting. There was, however, a history of sudden invasion, of vomiting of everything administered, of elevation of temperature, of great restlessness—symptoms that, taking the season and surroundings into consideration, all point to one morbid state, namely, heat-stroke.

It is true that the attitude of the child, a manifestation of the greatest importance in infantile symptomatology, seemed to point to the head as the seat of the morbid process, but the peculiar attitude is also one of the features of heat-stroke, even in its earlier stages. Obernier states that in heat-stroke, with a temperature of but 102° or 103° F., malaise, headache and rapid pulse are present.[1] Furthermore, it is probable that the greater prominence of the head symptoms was due to the reflection of heat from the ceiling upon the comparatively bare head of the infant, thus producing a greater degree of cerebral irritation than if the heat had been more equably distributed and its influence exerted upon the whole body.

Etiology.—As may be seen from the histories of the cases reported, nothing extraordinary occurred to which heat-stroke could be directly attributed. There was no undue exposure to the sun or to excessive artificial heat. There remains, therefore, as the sole etiological factor, the atmospheric heat of the surroundings, and the season, *i. e.*, the summer.

The surroundings of the little patients were such that the heat of a not excessively hot summer would readily suffice to give rise to thermic fever in infants, who are so very susceptible to the influence of heat. Case I. lived on the second floor of a two-story frame building, located in a narrow street at the foot of a hill with a tier of streets rising above it. The first floor was utilized as a bakery. Though the two rooms on the second floor were comparatively large, there was no ventilation; the windows of the front room opened on the narrow street, with much higher houses on the opposite side; the window of the rear room opened into a small court, with a large frame building at the further end, and beyond this there towered, one above the other, the houses on the tier of streets on the hill. The front room was divided from the rear room by a full partition-wall, communicating only by a narrow door, so that a free current of air was an impossibility. In the rear room all the cooking for the family and all the service requiring fire was done; the front room served as bedroom for father, mother, and four children. Owing to the narrowness of the street the front shutters had to be kept closed at night. To this must be superadded the location of the rooms—very near the roof (only separated from it by a small space)—and the heat created in the building by the bakery. In Case II. the family lived in a small back room of a tenement-house, with door and windows opening on a close court. This room was on the ground floor and served as a kitchen and bedroom for the mother and four children. Even on the hottest nights they were compelled to keep everything closed. That heat-stroke can occur in over-heated rooms is so well known and so well established that it needs no further proof here.[1]

Treatment.—After the labors of Jürgensen, Immermann, Liebermeister, and others, it would be a work of supererogation to enter into any long discussion as to the *rationale* and the propriety of hydriatric treatment of high temperature; if this be true of fever, in which the philosophy of its application is rather complicated,[2] it is certainly true of heat-stroke, in which the therapeutic indication is the rapid abstraction of heat. Naunyn thus clearly expresses himself on this point: "To avoid any misunderstanding upon this point I refer to it again and declare expressly and distinctly that in heat-stroke I regard the rapid cooling of the system with cold water an absolute necessity."[3] My manner of following out the indication for treatment has been given. The wet pack referred to was used as follows: a large muslin sheet was folded in its length and then in its breadth and wrung out of cold water; the naked child was wrapped in the sheet, placed in its bed or cradle and covered with a blanket. As soon as the sheet became warm, it was removed and replaced by another that had meanwhile been cooling in the water; this procedure was continued until the temperature reached the normal. I am so explicit on this point for the reason that my method of using the wet pack differs

[1] Naunyn, loc. cit., p. 59.

[1] Quain's Dictionary of Medicine, article "Sunstroke."

[2] Liebermeister, "Antipyr. Heilmethoden," Ziemssen's Handbuch der allg. Therapie, p. 15.

[3] Naunyn, loc. cit.

from that described by Winternitz[1] and by Liebermeister.[2] The method is easy of application. All who have had any experience with children know the difficulties attendant upon putting a sick child into a bath—and more especially a cold bath—the stratagems that must be resorted to, the struggles of the child in the bath, its cries—all certainly not beneficial to the little patient. In the wet pack the child is so comfortable, that it is only when the pack becomes warm that the child cries and shows any uneasiness. I believe that the wet pack as here described is a more powerful agent for the abstraction of heat than the cold bath. It is true that the cold bath produces a marked and rapid lowering of the temperature, but this effect is not permanent and after a longer or shorter period of time the temperature has again risen, frequently to its previous height. The cold bath must then be repeated.[3] The question that has presented itself to me is whether the shocks to the system consequent upon the use of the cold baths[4] may not have some deleterious action upon the organism. The wet pack does not produce so rapid a depression of the temperature, but, on the other hand, if applied as here detailed, it is not followed by a secondary elevation; the heat is abstracted gradually but continuously, and, in the time required for this gradual abstraction, the system has accommodated itself to the changed condition. In Cases I. and II., in which the temperature was very high and at a dangerous point, and in which as large and as rapid an abstraction of heat as possible was indicated, I applied the wet pack to the whole body. In Case III., however, in which the temperature was but 103° and no immediate danger threatened, I used only the limited pack, *i. e.*, a heavy towel folded three or four times, wrung out of ice-water and applied to a limited portion of the body—in this instance to the head. I believed that the chief source of trouble lay in the great heat reflected from the ceiling upon the head of the infant, and hence it appeared to me that the therapeutic indications, viz., an obviation of the cause and an abstraction of the heat already absorbed, would be accomplished by the limited wet pack upon the head. The result was all that could be desired. In the general wet pack I used only ordinary hydrant water; in the limited wet pack I resorted to ice-water, thereby greatly enhancing the refrigerant influence.

From all that has been said—from the careful study of the symptoms and a comparison of them with the phenomena produced in the experimental studies of the effects of heat, from a study of the etiological conditions and from the results obtained by the special treatment, I believe myself justified in claiming that "heat-stroke" or "thermic fever," as resulting from over-heated apartments, must be considered in the category of the summer diseases of infants. Though I have seen but the few cases here recorded, it cannot be doubted that many more have occurred and still do occur every summer in the large cities wherein a great part of the population dwells under conditions as unfavorable as, or even more so than, those referred to in the etiological section of this paper—for it certainly is not to be supposed that mine were the only cases that occurred; but they have hitherto remained unrecognized, being engulfed in that great vortex that is made to swallow so many things, to wit, cholera infantum.

The importance of recognizing the fact that heat-stroke is of more frequent occurrence than has hitherto been believed, and that it may be produced by the heat of apartments, is not to be underestimated—more especially as, from their symptomatology, these cases are apt to deceive. Cases I. and II. present many analogies to cases of cholera infantum. It is a fact that most cases of vomiting and diarrhea occurring in infants in the summer months are set down as cholera infantum. This accounts for my uncertainty as to the therapeutic measures to be resorted to in Case I., for, though this was a typical case of heat-stroke, my mind was so occupied with the previous history of vomiting and diarrhea that I looked upon it as a case of cholera infantum *in extremis*, in which nothing would avail, and had it not been for some previous experience with the wet pack I should not have dreamed of resorting to hydrotherapy. Although a careful study of the case afterward disclosed to me its true nature, when I encountered Cases II. and III. I was still in a state of uncertainty as to their true character.

Cases like the third are apt to be mistaken for cases of cerebral disorders. In fact, in West's *Diseases of Children*[1] we find a case of heat-stroke from exposure to the sun treated of under the head of cerebral congestion.

The recognition of the true character of these cases is therefore of vital importance, for upon the diagnosis will depend the correct and appropriate therapeutic measures to be resorted to. If correctly diagnosticated, appropriate measures (already indicated) will be instituted and crowned with success, even in desperate cases; if not, the patient may be dosed and medicated until death closes the scene.

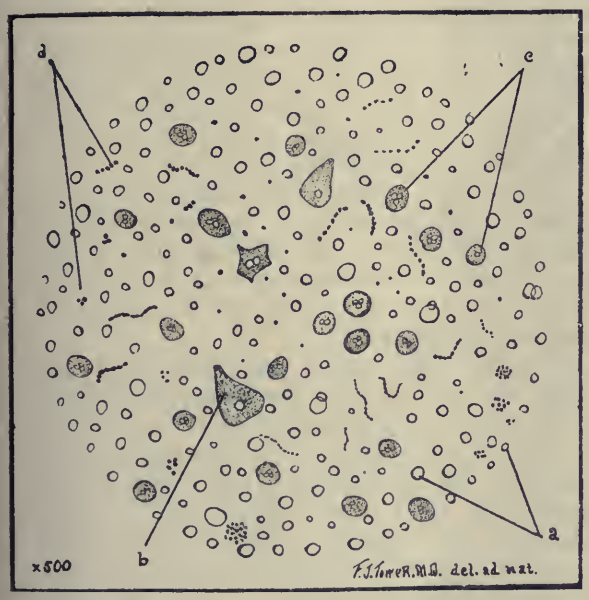
MILK INFECTION.

By F. J TOWER, M.D.,
of Milwaukee.

Considering that at least 7,000,000,000 gallons of milk are consumed in the United States alone, it seems a matter of more than little importance to appreciate the source of milk infection, especially when we find milk more ready than any other aliment to absorb poisonous substances and become a culture-bed for numerous germs and an undoubted carrier for such diseases as tuberculosis, anthrax, typhoid fever, diphtheria and scarlatina. How many cases even of tabes mesenterica and typhoid fever are caused by infected milk it is hard to say, but certainly a large per cent. can be traced to it. The origin of a late siege by an amœbic dysentery that one of the Eastern cities has had could undoubtedly be found in the adulteration of milk with water from a source contaminated with this amœba. Water from a stream upon which are situated distilleries, glue factories, wool-cleaning establishments, or which has sewers running into it, when drunk by cattle will infect the milk with many varieties of vegetable and animal life of a low form, and is very detrimental, not only when fed to infants and invalids, but causes diarrheas and gastric disturbances in healthy adults.

Fig. 1.



a. Milk globules. b. Epithelial cells. c. Pus-corpuscles. d. Cocci.

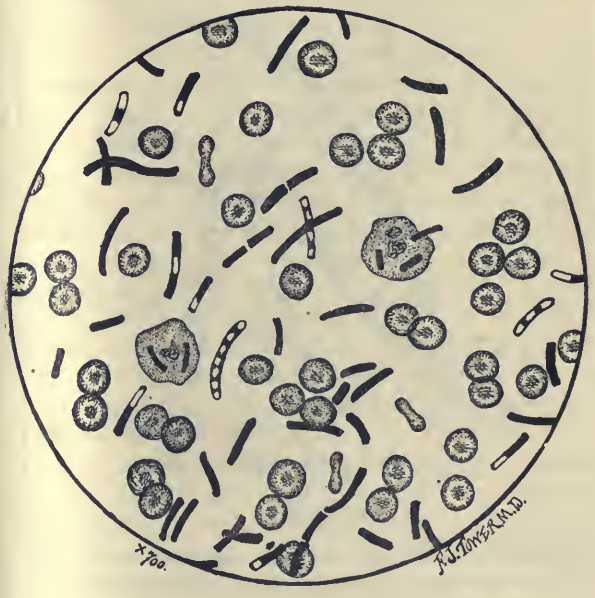
Varieties of Poisonous Milk.—1. Milk taken from a cow with garget, and allowed to stand for twenty-four hours, will on proper treatment and great care in manipulation, which is always necessary when treating for a ptomaïne, furnish an alkaloidal substance of which 0.01 gram injected subcutaneously in a rabbit will produce death in about sixteen hours. In Fig. 1 is seen the microscopical appearance of such milk, showing cocci, epithelial cells, pus-corpuscles and the milk-globules.

2. When adulterated with water into which the excrements of a typhoid fever case have found a way, the milk will give the Ehrlich diazo-reaction, which depends upon the formation of an anilin-red from the amine products of the bacillus typhosus. The destruction by disinfectants of the organisms in the feces does not necessarily render them innocuous, for the poisonous albuminoids still remain, and, administered with the milk in which they are found, produce a typhoid condition in animals.

3. Milk from a cow suffering with anthrax, taken in the quantity of 0.3 gram, and injected at the base of the tail of a mouse, will in two days kill the animal, and the blood will be found to teem with the bacillus anthracis. Fig. 2 shows a fresh cover-glass preparation of blood from a mouse killed by anthrax; the white corpuscles, of which two are seen, are entered by the bacilli.

4. The milk of an animal affected with any condition of debility or febrile disorder is viscid and will coagulate almost immediately on removal; it will be found to contain ammonium carbonate in very appreciable quantities, also several organisms, and appears under the microscope to resemble colostrum, which it is not, for a very small quantity of the milk added to fresh milk will produce a like condition. The reaction is very alkaline; the milk has a peculiar soapy taste, and the milk-globules are irregular in shape, the emulsion being poor.

Fig. 2.

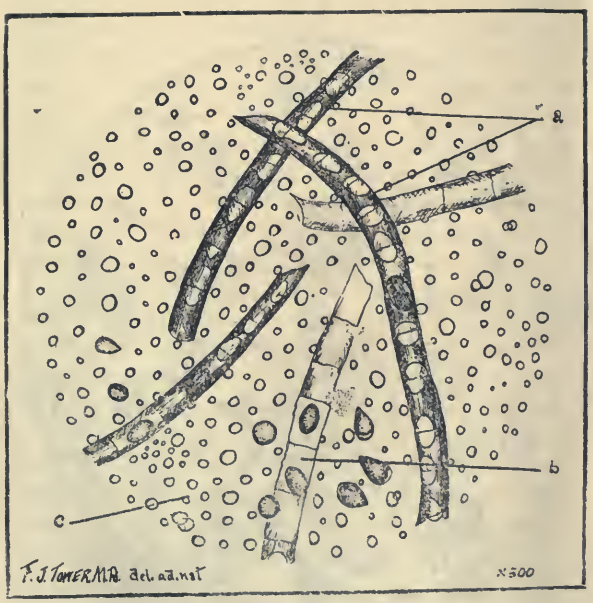


5. In milk which has stood in a damp place for twelve hours tyrotoxicon is found to such an extent

that many cases of poisoning are at present on record, and many more, in which the cause of death was only suspected, might have been traced to the presence of tyrotoxicon in food containing the milk. The cases of ice-cream and cheese-poisoning are in most cases due to the same agent. The frequent and even pardonable inability of the chemist to find the exact cause often leaves us at sea for a cause for the sickness or death, as oftentimes physiological experiments, and not chemical analysis, will determine for us the presence of the alkaloid. This tyrotoxicon is the product of several varieties of bacteria, as I have been unable to procure any pure culture from milk containing it. In warm weather, especially after much rain, and when the heat causes a slight vapor to arise from the ground of damp places, milk in a very few hours becomes poisonous. At such a time of the year, when infantile diarrhea is very prevalent, there is no doubt but that the milk in most cases contains the tyrotoxicon.

6. Among the coloring material used by dairymen to give skimmed milk a creamy appearance is a substance which is very frequently adulterated with red-lead, and the annatto (so called) becomes a poisonous substance, and quite unfit for use. One case of this kind has been reported. Saffron is also

FIG. 3.



a. Confervæ. b. Same, sporing. c. Milk-globules.

used as a coloring matter for milk, butter and cheese, but as the oil of saffron is not miscible there is slight danger from the effects of the ingested saffron.

7. Milk from a swill-fed cow I find to contain one of the confervæ, a low order of vegetable life—in fact, an alga. The fats are deficient, the milk is thin in consistency, and of a faint bluish tint, very much like skimmed milk. In Fig. 3 is shown a specimen of milk such as I describe.

8. In many milks there is found the oïdium lactis, which is a penicillium, and seems to exert a very detrimental influence upon young bottle-fed children. Whether it is the actual presence of the oïdium or the inferior quality of the milk that causes the disturbance, I have not demonstrated.

Colored Milk.—1. Blue milk has a very disagreeable taste, and when drunk will produce very severe gastritis and diarrhea. The bacillus cyaneus is the cause of the blue color. There are two varieties of blue milk—that which is blue when milked and that which becomes blue upon standing. The former is very slightly poisonous, while the latter is very much so. Both contain the bacillus, but the grade of toxicity is determined by the non-development of one and the maturity of the other.

2. Yellow milk. Beside coloring matter introduced by the dairyman to make the milk appear richer, there is found a bacterium xanthinum, and also a vibrio xanthogenus, which are found in a pure culture on glycerin-agar and on nutrient gelatin to produce a yellow film; the bacterium is aërobic, so that the lower portions of the milk are apt to be free from the growing organisms, though it will contain the products and may even be more deleterious in its effects than the upper stratum. The eating of rheum palmatum or some of the orchids will give milk a yellow color. I have found a penicillium the spores of which are yellow growing on milk left for a few days exposed in dry places to the atmosphere, giving an appearance of grated lemon-peel upon the surface of the milk.

3. Red milk usually comes from feeding the animal madder or galium (called also bedstraw). The spirillum rubrum will grow on milk, though there are no cases describing such a condition. At rare times blood finds its way into milk, and gives it a reddish hue.

4. Brown milk. Among many experiments made during the past year I find that on exposing milk to the air of certain localities a fungus will occasionally be captured, the products of which are brown, which extending into the surrounding milk give it a rusty-brown color. The spore-growth of this one of the fungi presents no difference from that of the oïdium lactis. It thrives better when a small per cent. of cane sugar has been added.

5. Green milk is very rare. It may possibly arise, under some circumstances, in ulcer of the udder, from the presence of the same organism which causes green pus, though I have not seen such a condition. Green milk as it does actually occur is due to two causes, one a physical cause and the other organismal. From the first: a very large amount of fat is found, so that the emulsion is poor, and the fat in

masses throughout the milk gives it a greenish tinge. From the other: when the causes of blue and yellow milk are both active in the same milk, this appears green in color; the result is a mixed culture divisible into the two distinct varieties.

Odors, etc., of Milk.—The natural odor of milk is due to a minute proportion of H_2S, which rapidly leaves it, and we fail to get the faint animal smell. Owing to the presence of the albuminoid substances, *i. e.*, casein, sodium albuminate, etc., there is great liability to fermentation and to absorption of odors from its surroundings. When a quantity of milk is left exposed to any noxious gas, it becomes contaminated within a very short space of time.

The normal amphioteric reaction of milk well suits it as a medium for the growth of low forms of vegetable life. Take the torula, for instance—though cane sugar is necessary for its growth. In milk to which saccharose has been added, the yeast-plant finds a feeding-ground, and breaks up each molecule of grape sugar, into which probably the cane sugar has first been changed by a simple hydration—

$$C_{12}H_{22}O_{11} + H_2O = 2C_6H_{12}O_6$$
$$C_6H_{12}O_6 = 2C_2H_5HO + 2CO_2$$

the carbonic dioxide rising in bubbles and the alcohol remaining in solution in the milk. Upon this property of yeast is founded the manner of koumyss-manufacture.

If the clostridium butyricus finds an entrance into milk it changes the lactic to butyric acid, and the milk then has the faint pineapple odor of that acid. This may occur when milk is even sealed up from the air, provided the clostridium gains an entrance to the milk before sealing, for the organism is an anaërobic bacterium, and does not need oxygen for its growth.

When the cow suffers from any disease of the liver that prevents proper elimination of the bile-acids and salts, the milk will be exceedingly bitter. There is no difference between the taste of such milk and that which comes from the cow after the ingestion of leaves of the chestnut tree. When even a small quantity of the plant symplocarpus fœtidus is eaten, the milk has an odor quite equal to mephitus itself; not so bad, but still sufficient for those who dislike onions, is the odor when any of the allia are eaten. Turnips fed to cows impart their taste to the lacteal fluid.

A few words upon the vitality of the commoner growths in milk will not be out of place in this sketch. When the alcohol in milk undergoing yeast-fermentation reaches about 6 per cent. the growth ceases—is, in fact, destroyed by its own production. This is true in all cases, but in some it takes a much longer time for the growth to exhaust itself, as it may be slow or the organism a particularly resistant one. Organisms, if left to themselves, die or cease to grow from one of two reasons: one, when they exhaust the material in the pabulum favorable to their growth and propagation; and, secondly, when they produce a substance poisonous to not only many higher grades of life, but to themselves, as, when the torulæ produce alcohol, or the tubercle bacilli an alkaloidal substance. The vitality of the tubercle bacillus is far greater than that of any other microörganism commonly found in milk, some of which containing the bacilli may be boiled for four minutes, and if an inoculation be then made upon sterilized blood-serum, the growth, though somewhat tardy, will take place. The gastric juice does not destroy them. For a fluid medium a spit-culture is one of the best to make. Milk should always be boiled for thirty minutes, bottled, and then allowed to cool, and there will be no danger in using it. The spores of the tubercle bacillus may even be demonstrated by successive cultures though not seen in the specimen, for they do not stain in milk that contains them. Milk that has been treated with carbolic acid for fifteen hours will make successful cultures; not until from eighteen to twenty hours will the bacilli be destroyed. As a comparison of vitality the cultures of staphylococcus aureus are checked by a 1 to 30,000 iodine solution, while moist heat (100° C.), the best of all sterilizers, fails to destroy the tubercle bacillus in several minutes.

Now to descend upon a more practical footing, where our remarks will apply to everyday protection. Always suppose that every milk is dangerous to health as it is freshly received; boil for thirty minutes, ascertain that it contains no fungoid growths, has a specific gravity of about 1.033, contains 3 per cent. or more of fats, and approximately 4 per cent. each of lactose and albuminoids (casein, etc.).

RARE COMPLICATIONS OF TYPHOID FEVER.

By EDWIN E. GRAHAM, M.D.,
CHIEF CLINICAL ASSISTANT OF MEDICINE IN JEFFERSON MEDICAL COLLEGE; PHYSICIAN TO FRANKLIN REFORMATORY HOME.

The publication of an exhaustive article on "Rare Complications of Typhoid Fever," by Professor H. A. Hare and Mr. Arthur J. Patek, in The Medical News of June 20, 1891, in which they report two cases of typhoid fever that were ushered in by mania, induces me to report the following case that occurred in the practice of my brother, Dr. James Graham. In this instance I am of the opinion that the typhoid fever ushered in the mania, the tendency to insanity having previously existed.

Dr. Hare and Mr. Patek clearly show that, in a disease as common as typhoid fever, mania coming

on early is an exceedingly rare complication. Might it not be that in some of the cases cited the typhoid fever was the complication, for they were mostly hospital cases, and in hospital practice the patient is apt to be a stranger, ignorant of his hereditary tendencies, or, as appears to be common to all classes, conceals insanity in his family as he would crime.

I was called June 12, 1891, to see for the first time John T., aged twenty-two years. He was lying upon a settee on the first floor, and his mother, an exceedingly nervous woman, was bathing his head. She informed me that her son imagined himself "under a spell," put upon him by the young lady to whom he was engaged to be married. He was of temperate habits, had been in good health, and at work as an employé in a store until two days previously. When upon returning home after spending the evening with some friends, but unattended with any excitement, "he had acted queerly," would not answer questions, but said that "the spell was upon him." He immediately informed me that some girl had cast "a spell upon him," but upon being questioned he remained quiet, with his eyes intently fixed on the ceiling, and did not answer or appear to hear me. His skin felt cool, and his pulse was but slightly increased in frequency. The mother reluctantly admitted that his father had been insane, and had been confined in an asylum, but knew of no other member of her own or of her husband's family who had shown any evidence of insanity. The patient was her only child.

The case appeared to be evidently one of insanity, and I advised that he be closely watched for a short time, and if no signs of improvement were shown to send him to an asylum. I was again called the following day, and, although awake and evidently conscious, he paid no attention to my questions. His mother reported that he had been excitable through the night, and that he was constipated. I ordered fluid extract of cascara sagrada. Two days later I was again summoned to see him, as he had escaped in the night while his mother was temporarily absent, and was found the next day in the station-house, where he had been locked up by the police on a suspicion of robbery, as when arrested he had a clock and some articles of female attire in his arms. Upon attempting to undress him when he arrived home his struggles were such that it required four men to control him. I did not see him until four days later—a week after my first visit. His mother, who was now quite frightened and exhausted, earnestly requested that he be transferred to an asylum. She reported that he had on several occasions been extremely violent, that four men had with difficulty been able to control him, and it had been necessary to tie him in the bed. He had also entered a neighbor's dwelling, where he heard some singing, with the intention of "clearing out the house," and was only restrained by the persuasion of another neighbor, whom he called "the Virgin." My visit had the same negative results. Accordingly the necessary papers testifying to his insanity were filled out by myself and another physician—one of large experience. Four days later I was called upon for a death certificate, but suspecting that he had committed suicide I referred the family to the coroner, and the coroner's physician, on post-mortem examination, found that he died from typhoid fever.

It was unfortunate that I had not taken his temperature, or made any notes as to his physical condition. But his temperature had seemed normal, and the case appeared to be evidently one of uncomplicated insanity. It was also difficult to get any accurate information.

The following case presents another complication that may arise during the course of enteric fever, *i. e.*, hemorrhage:

Gracie M., eight years old, died January 21, 1891, of typhoid fever, on the twenty-fourth day, apparently from exhaustion. Two sisters were taken down with the disease about the same time. Gracie had a slight initial epistaxis, and from the ninth to the thirteenth day slight, almost constant, oozing of blood from the nose, and also from the mouth, eyes, ears, vagina and anus, although these hemorrhages were less in amount, and less constant. There was no heart or kidney complication, and no history of hemophilia in the family. The bleeding did not seem to influence the course of the disease. The other child, three years older, had a milder attack and recovered. Previous to this illness Gracie had always been a strong, healthy child.

In looking over the literature of the subject I can find no case in which the hemorrhage was of such a universal character as in the case here reported. W. W. Powell[1] reports a case of severe hemoptysis in enteric fever ending in recovery, and not followed by any signs of disease of the lungs, either tuberculous or otherwise. William Madden,[2] in an elaborate discussion on the complications and sequelæ of typhoid fever, devotes only a few lines to hemorrhages from other portions of the body than the bowel, and says: "Hemorrhage in children is not so frequent as in adults, because of the superficial character of the intestinal ulcerations in the very young." Parrot relates the case of a child three years old that died from a sudden intestinal hemorrhage. He says: "Epistaxis is as rare in children as it is frequent in adults; occasionally it is profuse." Uterine hemorrhage is not uncommon. According to Beach:[3] "Phlebitis, arteritis, endocarditis, pericarditis, thrombosis and infarctions with their results, have been observed as occurring in connection with typhoid fever." Some of these conditions may be either complications or sequelæ, and may arise from the action of the specific poison on the endothelium, the condition of the blood or lymph, the state of the circulation, or from external pressure.

CASES OF GASTRIC ULCER CURED BY A DIET OF ICE-CREAM.

Clinic of Prof. J. M. Da Costa.

Reported by E. P. HERSHEY, M.D.,
of Denver, Col.

Case I.—In September, 1888, A. E. L., thirty-five years of age, unmarried, presented herself at the clinic. Three months previously the patient had applied for the treatment of what she considered aggravated dyspepsia. The symptoms then were localized pain in the epigastric region, more intense on pressure. The corsets had to be put aside, and later on the parts became so sensitive that the front of the dress could not be fastened. At first, food was rejected about from twenty to thirty minutes after it had been taken into the stomach; but later on, it was expelled at once. Blood appeared in the vomited matter—indeed on one occasion there was distinct hematemesis. Some weeks previously to her visit to the clinic, the patient had eaten a small quantity of ice-cream, and to the surprise of all, it was retained by the stomach. After this she constantly expressed a desire to have an unlimited quantity of this agreeable nourishment, but owing to the fears of the attending physician as to its possibly injurious effect, she was allowed but a little.

At the time when she applied at the clinic she complained of continuous pain extending from the epigastric region in front, to a point between the first lumbar and the last dorsal vertebra; the slightest pressure over either of these regions was unbearable. During the first three months of her illness, she had lost twenty-five pounds in weight. Every article suggested as a means of diet was met by the answer that it had already been tried. It was advised that the patient be given iced milk with thirty drops of the aromatic spirits of ammonia to the glassful; should this fail, rectal alimentation to be resorted to. Ten days later it was reported that the patient rejected the medicated milk, and that all artificially digested foods given per rectum were spasmodically expelled; so this means of nourishment had to be discontinued. At the suggestion of Prof. Da Costa, the patient was then allowed ice-cream *ad libitum*. No attempt at medication was made, as every drug, whether given in capsule or liquid, was vomited as soon as it reached the stomach. The occasional severe paroxysms of pain were relieved by hypodermatic injections of morphia.

After the patient was allowed her choice of diet, all severe symptoms gradually began to disappear. From two to three quarts of ice-cream were at times eaten during the twenty-four hours, the smallest quantity taken on any day having been one quart. At the end of two months, the patient had gained twenty-four pounds in weight; all severe symptoms had disappeared, and solid nourishment was gradually added to the diet, until the patient made a complete recovery.

Case II.—One year later, another patient, M. H., a laborer, presented himself at the clinic with the same history as the case reported, except in severity, the gastric irritability being very great. He had some weeks before discovered that the only food that he could retain was ice-cream. This article he was urged to continue, which he did for about a month, when the improvement was so great that he was put on a carefully selected diet of solid food. He also made a complete recovery. In this instance, however, medicine was tolerated, and he was given one-quarter grain doses of the nitrate of silver three times a day.

To these cases appearing at the clinic, the following, which happened in the practice of the reporter, may be added:

Case III.—In August, of last year, a young lady came under observation with symptoms of severe pain in the epigastrium, extending as low down as the umbilicus, and throughout the left hypochondrium. There was a history of constant distress in the stomach for one year, and food was rejected as soon as it entered the stomach. Hematemesis was of frequent occurrence, and the taking of food always occasioned distressing pains. For three weeks previously to the time the case was first seen the patient had attempted to take no food other than milk and lime-water, and even this was frequently vomited. She was confined to her bed; there was decided tenderness upon slight pressure throughout the region of pain; the knees were drawn up. The temperature was 103°, the pulse 130, and weak. The ulcer had perforated the walls of the stomach, and localized peritonitis had followed. The stomach was at once put to rest; rectal alimentation was resorted to, including principally peptonized milk and beef peptonoids. Hot turpentine stupes were applied to the affected area, and opium was administered by the bowel until slight narcosis was produced. In four days all signs of peritonitis had disappeared. Upon the fifth day an attempt was made to give nourishment by the mouth. The patient was given peptonized milk, but this occasioned severe pain and vomiting and had to be discontinued. Acting then upon the experience gained from the cases reported, the patient was given a small quantity of ice-cream, pure and freshly made; this she retained, and on this diet she was kept for nearly two months, gaining rapidly in strength. The particular advantage of the diet was that it neither nauseated nor distressed her. During the third month, solid food was gradually added, until a plain substantial diet could be indulged in without distress. Following this condition, there were marked symptoms of gastric catarrh, which were greatly lessened by means of lavage.

It is most likely that the ice-cream in these cases acted partly in virtue of the cold, which, as a local anesthetic, benumbs the stomach, permitting the act of digestion to go on without pain, and the nourishment to be appropriated. In using ice-cream as a diet in cases of gastric ulcer, too great care cannot be taken in seeing that the article is perfectly fresh, and contains no corn-starch or other ingredients to thicken it. That which is over twenty-four hours old should not be used. Ice-cream may

not answer in all cases, but it will be found a most excellent article of food to resort to when other foods cannot be retained. It is a conceded fact that many cases of gastric ulcer get well of themselves, provided the stomach be kept at rest. If, then, an article of diet be given which will allow of the desired rest, and at the same time nourish the patient, we have the best means of bringing about a speedy recovery. By the presence of some food in the stomach we prevent the continued corrosive action of the gastric juice upon the affected surface, a fact that certainly should be taken into consideration when the plan of rectal alimentation is entertained.

The only objection that could be taken to this form of diet is in the risk of giving impure ice-cream. There is undoubtedly danger in the hot summer months. All such risk, however, may be obviated by allowing only that to be eaten which has been made at home.

A FATAL CASE OF PURPURA HÆMORRHAGICA.

BY D. J. MILTON MILLER, M.D.,
PHYSICIAN TO THE EPISCOPAL HOSPITAL, PHILADELPHIA.

THE extreme rarity of rapidly fatal forms of purpura among adults, and the unusual character of the following case, are sufficient explanation for placing it upon record:

M. H., a healthy male, of splendid physique, twenty-one years old, living amid good hygienic surroundings, and of good family history, was admitted to the Episcopal Hospital on April 3, 1889. He had always enjoyed good health until his present illness, excepting an attack of typhoid fever nine years, and of gonorrhea four months, before admission. The illness on account of which he sought admission began March 29th, after exposure to cold and wet (to which he ascribed his illness), with sore throat, general malaise and aching of the bones, followed in two days by swelling in one finger, and, on April 1st, by pain and swelling of the ankle- and knee-joints; at the same time purpuric spots were noticed on the feet and legs. The symptoms progressed until his admission, when he presented the following appearance: Both ankles, the left knee, both wrists, the left elbow, and the right shoulder were swollen, painful and edematous, some more so than others; on the anterior aspect of both legs, on the forehead and about the alæ nasi were numerous purpuric spots, varying in size from a split pea to the nail of one's little finger. Similar spots, though larger, were noticed on the buttocks and left hip. These spots were dark-purplish in color, the larger ones slightly elevated above, the smaller ones on a level with, the surrounding skin. The left tonsil was much swollen, dark-blue in color, and the seat of great pain; the tongue was moist and clear; the bowels were constipated; there was some nausea; the temperature was 99°; the pulse was 100. On the next day, April 4th, the hemorrhagic spots were much increased in size, especially those on the buttocks and hip-joint. This joint was swollen and edematous, painful on pressure, and presented on its outer surface a large extravasation of the size of a man's hand, while new spots and patches had appeared on the arms, abdomen and left eyelid, which was edematous and dark-blue in color. The enlargement and discoloration of the left tonsil had diminished, but a bluish patch was noticed on the uvula and posterior portion of the hard palate. The patient complained of much pain in the throat. His general condition continued good. The morning temperature was 99°, the pulse 92; the evening temperature 100.4°, the pulse 96. On the 5th the left eye was completely covered by the edematous and blackened lid; a similar process was beginning on the right. The right shoulder was twice its natural size, edematous, and covered by a large extravasation that extended up the neck almost to the ear, the area involved being of the size of *two hands*. On the right arm, midway between the shoulder and the elbow, was another smaller hemorrhagic patch, fully three inches in its greatest diameter. The other joints had diminished in size and were free from pain, while the purpuric areas about them and on the lower extremities and abdomen were undergoing the changes peculiar to subcutaneous extravasations of blood. The morning temperature was 99.6°, the pulse 96; the evening temperature 100°, the pulse 102. By noon, April 6th, the tongue was attacked and rapidly filled up the oral cavity, rendering swallowing almost impossible; its surface was livid, almost black, a large hemorrhagic patch, accompanied by swelling and edema, appeared just below the lower lip, and extended over the chin to the hyoid bone. The front of the neck was much swollen, the swelling adding to the difficulty in swallowing already caused by the condition of the tongue. The other extravasations and swellings were rapidly subsiding. The patches on the right shoulder and arm, however, had become depressed below the surface, and of a deep-black color. An enema brought away a copious tarry stool. The patient was weak and anemic-looking. The morning temperature was 100.6°, the pulse 108; the the evening temperature 101°, the pulse 106. On April 7th the swelling of the tongue had subsided sufficiently to permit of some swallowing. The neck had also diminished in size. New spots were seen on the chest and back. The joint and other swellings had completely subsided, leaving nothing but the fading extravasations. The urine, previously clear, was now dark and smoky; it was, unfortunately, not examined. Slight cough was present, with blood-stained sputa. Numerous subcrepitant râles were heard over the bases of both lungs. Morning temperature was 101.2°, the pulse 108; the evening temperature 101.6°, the pulse 108. On the morning of April 8th, the tenth day of the disease and the eighth of the eruption, the patient was very weak. He expectorated abundant frothy, bloody sputa; the breathing was accelerated to 36 per minute; there was percussion dulness over the left base, where bronchial breathing and subcrepitant

râles were heard; elsewhere, throughout both lungs, there were large bubbling râles. The urine was darker, and contained a few clots. The extravasations on the right shoulder and arm were still depressed below the surface, *and presented the dry and shrivelled appearance of a part about to become gangrenous*—an indication that gangrene would, without doubt, have supervened had death been deferred a little longer. The morning temperature and pulse were 101.8° and 120 respectively. The dyspnea and the signs of pulmonary congestion and edema increased until death occurred at 6 P.M. Just before the end the temperature registered 103.2°, pulse 140. An autopsy was not permitted.

As to the treatment there is little to be said. At first, owing to the prominence of the joint symptoms, sodium salicylate was administered. On April 4th, when the true nature of the disease became apparent, the salicylate was discontinued, and half a drachm of fluid extract of ergot and twenty minims of the tincture of the chloride of iron, every three hours, were substituted. When symptoms of adynamia set in whiskey was added. Morphia, subcutaneously, was also given for the very intense joint pains. Upon the onset of the pulmonary symptoms the chest was frequently dry-cupped. The diet consisted of milk and meat-broths. But it is probable that, in a disease of so malignant a character, treatment of any sort would have been futile, and a report of the treatment is only added to complete the clinical history.

What was the nature of this almost fulminant attack? In the present obscurity and uncertainty surrounding the pathology and etiology of purpura, it is useless to speculate concerning the cause of the striking symptoms just narrated. Recent investigations point to a mycotic origin—either a direct action of microörganisms or the development of a poison by their growth. The impression made upon the writer as he saw this robust man sink under the external and internal hemorrhages, was the strong resemblance of the attack to the hemorrhagic form of the acute infectious diseases. So far there has been little that is convincing in the work of the advocates of the infectious nature of purpura. The researches of Martin de Gimard,[1] however, are more conclusive. This investigator has found micrococci in the blood of purpuric patients during life, and in the hemorrhagic patches and viscera after death. Injections of fresh blood taken from living purpuric patients into the bodies of rabbits failed to cause hemorrhages, but pure cultures in bouillon and agar-gelatin preparations injected into the cellular tissue, the peritoneum, and the veins of the ear of rabbits and of guinea-pigs gave rise to ecchymoses of the thigh and to hemorrhagic infiltrations in the peritoneum, in the capsule of the kidney, and in the small intestines. He ascribes the purpuric lesions to a mechanical obstruction of the vessels and to inflammation of their walls from the presence of colonies of micrococci, rupture occurring spontaneously, or as a result of movements on the part of the patient. The Medical News of May 23, 1891, contains an abstract of a paper by Letzerich, in which the disease is also etiologically ascribed to a microörganism, but the author does not appear, like Gimard, to have produced hemorrhages in animals. Whether or not purpura is really of microbic origin future investigation only will determine, but to the writer it seems the most likely explanation of the remarkable case reported in this paper.

CLINICAL MEMORANDA.

TREATMENT OF SPINA BIFIDA.

By E. P. HURD, M.D.,
of Newburyport, Mass.

On reading an article published in The Medical News of May 16, 1891, by Dr. Ira K. Gardner, on "Excision of Spina Bifida," I was impressed by the fatal neglect of the operator to tie the neck of the sac before closing up the wound with sutures. Had that precaution been taken, I believe that the life of the little patient might have been saved. I speak from experience, having had a similar case in 1889, where, but for the interference of my friend, Dr. G. W. Jones, of Cambridgeport, I should have operated in the same manner as Dr. Gardner and his partner. Dr. Jones insisted on the necessity, before excision of the sac, of putting a firm chromicized catgut ligature around the neck, without which there would certainly be persistent and ultimately fatal escape of the cerebro-spinal fluid, which no amount of sutures of the integument, adhesive strips, and pressure could prevent. The operation was done as Dr. Jones suggested and the child is to-day in perfect health.

This case was reported by me in the *Therapeutic Gazette* for October, 1889, in an article with the heading "Operative Treatment of Spina Bifida." This article has received the commendation of distinguished surgeons, among whom I may mention Dr. Robert Abbe, of New York, who writes me: "Your operation, which is essentially Mayo Robson's, is the only safe one."

I will quote from this article that portion describing the operation as performed by Dr. G. W. Jones and myself:

"Wednesday, September 11. Ether was administered and the operation was performed under thorough antiseptic precautions. Once during the operation it was necessary to rally the failing heart by a hypodermatic injection of ether. An incision was made over the tumor, freely exposing the inside of the sac; the cavity was sponged out with a sublimate solution (1:2000). The glistening sac, with its arborescent nerve-filaments and median-core, was dissected or torn from its subjacent tissues till we had the entire membrane in our hands down to the foramen of entrance into the vertebral canal. Behind the neck of the sac (and by this term I mean the constricted portion before mentioned where the sac passed up into the spinal canal) was a large pulsating artery, which was carefully avoided. A stout catgut ligature

(that had previously been well chromicized to make it more enduring) was passed around the neck of the sac and twice firmly tied and the entire sac was then excised; iodoform was freely dusted over the raw surfaces, and a continuous (buried) fine catgut suture was taken, attaching the deep layer of the skin in front to the fascia, which had constituted the posterior boundary of the sac; this running *blind* stitch was entered from above and below until it finally ended in the edges of the cutaneous flaps, which were also brought together by a buried catgut suture (blind stitched); iodoform was applied once more and the line of incision finally closed in with flexible collodion. A compress and bandage completed the operation."

It will be seen that the above was strictly a hernia operation, performed according to Marcy's methods, as described in his recent treatise on *The Radical Cure of Hernia*. The sac with its contents originally belonged to the spinal canal, and had become a hernia by protrusion through a weak place in the last lumbar arch. The foramen of exit corresponded to the abdominal ring, which gives passage to intestinal hernia.

The ligation of the sac by chromicized catgut is according to Marcy's plan of dealing with the sac of abdominal hernia, and the stitching of the deep and superficial parts together by a running catgut thread and the final closure of the cutaneous incision with catgut and collodion are also like the abdominal operation.

CANCER OF THE BREAST CURED BY OPERATION.

BY WILLIAM M. LEWIS, M.D.,
OF GREENSBURG, KY.

IN the autumn of 1885 Mrs. S. B., fifty-one years of age, was examined for a "lump in her breast." Her health had always been good and she was the mother of eight healthy children, all grown. Her family history was somewhat alarming, as her father died of cancer of the stomach, and an aunt died of mammary scirrhus. The patient had noticed the growth about six months before, when it was the size of a walnut. She sought medical aid on account of the rapidity of the growth. It was found to be as large as a double fist, occupying the outer segment of the gland. The nipple was retracted and the axillary glands were enlarged and slightly tender; the tumor was freely movable, but attached to the skin beneath and to the outside of the nipple, and over this portion of the gland enlarged tortuous veins were plainly visible.

The diagnosis of carcinoma was made and soon after confirmed by Dr. David W. Yandell, of Louisville, Ky. Early removal was advised, and on November 12, 1885, with the assistance of Drs. Hazlewood, Buchanan and E. J. Graham, the entire diseased gland was removed. The incisions were well away from the mass, in healthy skin and tissue, and all the axillary glands were carefully removed. A drainage hole was made at the most dependent part, and the wound brought partly together with silk sutures. Moderate pressure was applied. Healing was by very profuse suppuration. The space from which the gland was removed granulated from the very bottom. Recovery was uninterrupted, and the lady's health has continued good all the time.

Now, nearly six years from the date of the operation, a very careful examination fails to elicit a single symptom of return of the neoplasm in or near the cicatrix, or elsewhere.

This case is reported for its value in a statistical point of view, and it proves that, under favorable circumstances, cancer of the breast is curable by excision. For the benefit of those who may doubt the diagnosis I desire to add that on section the tumor exuded a milky juice, and under the microscope the characteristic stroma and cells of the scirrhus variety of carcinoma were plainly seen.

A VERY IRREGULAR FOREIGN BODY IN THE ALIMENTARY TRACT SAFELY VOIDED UNDER THE "POTATO" TREATMENT.

BY J. SOLIS-COHEN, M.D.,
HONORARY PROFESSOR OF LARYNGOLOGY IN THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

A PATIENT was recently brought to me some two hours after having swallowed the irregularly shaped dental clasp depicted full size in the figure.

Exploration of the esophagus showed that tube to be unobstructed. The patient was ordered to feed exclusively upon buttered mashed and roasted potatoes, and to examine his stools carefully for the foreign body. Within forty-eight hours the patient left the object at my office door. It had been voided thoroughly coated with potato, to free it from which several washings had been required.

NOTE.—Had this very irregular body been found impacted in the esophagus, the same treatment would have been pursued in preference to the infliction of injury upon the esophagus in efforts at forcible extraction.

MEDICAL PROGRESS.

The Detection of Arsenic in Wall-paper.—A piece of the suspected paper is placed in strong aqua ammoniac. If arsenic be present a bluish color is developed. The presence of copper would give a similar reaction. If, however, a crystal of nitrate of silver be moistened with the fluid, the presence of arsenic is revealed by the development of a yellow color.—*National Druggist*, May 15, 1891.

Stain for the Medullary Sheaths of Nerves.—WEIGERT (*Münchener medicin. Wochenschr.*, June 16, 1891) has recently modified his method of staining the medullary sheaths of the nerves in such a way as to obviate the chromate of copper precipitate that is so injurious to the knife, and so that a differentiation by the method of Pal, with the danger of entirely decolorizing fine fibres, is not necessary. The hardened tissue is placed in equal parts of a cold, saturated and filtered solution of acetate of copper and a 10 per cent. solution of Rochelle salts, and kept for twenty-four hours in a thermo-

stat, then for twenty-four hours more in the solution of copper. The sections may now be stained without the necessity of differentiation. The staining fluid should be strongly alkaline—seven c.cm. of carbonate of lithium solution, instead of one c.cm. The mixture of the alcoholic solution of hematoxylon and the solution of carbonate of lithium must always be freshly prepared. After the sections have been stained for several hours in the thermostat the fibres appear blue; after a longer period the fibres appear black; the background is pale-rose. If the stain should be too deep, decolorization can be done as in the earlier method. In series-sections a blue tint imparted to the celloidin can be removed by a dilute solution of acetic acid. Anilin-oil-xylol (2:1) is recommended for clearing up.

When to Discontinue Mechanical Treatment in Hip-joint Disease.—At a meeting of the Section on Orthopedic Surgery of the New York Academy of Medicine, Dr. Newton M. Shaffer called attention to the difficulty which often existed in deciding when to discontinue mechanical treatment in hip-joint disease. The following conditions contra-indicated the removal of the apparatus: If manual concussion produces pain or flinching; if there is considerable deformity without ankylosis; if there is a true joint-limp, or if there are abscesses or sinuses connected with the joint; or if there is a true reflex muscular spasm, limiting movement slightly in all directions; if there is almost perfect flexion, with the other movements considerably or markedly limited; if flexion, abduction and adduction are excellent, with rotation and extension limited; and, finally, if all the movements are almost normal, except rotation inward during flexion (the limitations being due to the neuromuscular protection).

The Pathology of Diabetes Mellitus.—At the Tenth Congress for Internal Medicine, at Wiesbaden, Sandmeyer (*Deutsche medicin. Wochenschr.*, June 18, 1891) reported a fatal case of diabetes in a boy nine years old. The disease was first recognized at seven years of age. In the terminal coma, diacetic and oxybutyric acids were found in the urine. The urine contained but a trace of albumin, but many casts. A history of syphilis and an hereditary predisposition to diabetes were excluded. The autopsy was made seven hours after death. The pancreas was carefully examined, but no changes were found. The floor of the fourth ventricle was normal. Microscopically, the kidney presented evidences of glycogenic degeneration and characteristic fatty degeneration of its epithelium. The heart was involved in fatty degeneration.

Sterility in the Adipose.—Kisch (*Wiener Medizin Presse*, No. 21, 1891) has observed, both in man and in animals, that the adipose are especially prone to be sterile. This he ascribes to physical difficulties in the way of a perfect execution of the sexual act, to deficiency in number and virility of spermatozoids in the seminal fluid on the part of the male, to menstrual derangements on the part of the female and to diminished sexual desire on the part of both male and female. The prognosis is not unfavorable, if a rational therapeusis be instituted, directed to a reduction of the excessive deposit of fat, and to a removal of local pathological conditions in the genito-urinary tract.

Senile Chorea.—A woman, seventy years old, was admitted into King's College Hospital, London, under the care of Dr. Ferrier, with typical choreic movements of the right side of the body, face, arm and leg. She passed a sleepless night, and on the following day became maniacal. Under treatment with chloral, bromide, quinine and arsenic, recovery ultimately took place. The patient had no history of acute rheumatism, nor was there a family history of either rheumatism or chorea. The patient, herself, had eleven months previously had an attack of left-sided chorea that came on gradually and lasted two months.—*Lancet*, June 20, 1891.

Acute Hypertrophy of the Mammary Glands.—Crofford (*American Journal of Obstetrics*, June, 1891) reports the case of a girl, fifteen years old, in whom the breasts attained such proportions that, other means failing, amputation was performed. When removed, the right breast weighed thirteen pounds, the left eleven and a half. The tumors appeared to have been nourished by the superficial rather than by the deep vessels. Microscopically, the condition was found to have been an acute diffuse hypertrophy or fibro-adenoma.

Classification of Mental Disease.—Dornblüth (*Münchener med. Wochenschr.*, June 2, 1891) makes the following classification of the primary forms of mental disease: (1) Melancholia; (2) mania; (3) acute insanity (*verwirrtheit*); (4) acute dementia; (5) paranoia; (6) periodical insanity; (7) neurasthenic insanity; (8) hysterical insanity; (9) hypochondriacal insanity; (10) epileptic insanity; (11) acute delirium; (12) progressive paralysis (dementia paralytica); (13) cerebral syphilis.

The Refuse of Cities.—According to an abstract in *The Sanitary News*, July 4, 1891, the town of Chelsea, in England, since two years, disposes of its refuse by a method of sifting, grinding and incineration, by which the utilizable portion of the materials collected is separated from the useless. Special devices overcome the nuisances that would otherwise arise from the dissemination of bad odors and from the smoke generated. The products obtained are used as fuel, for making brick and paper pulp, and for fertilizing purposes.

Fracture of the Clavicle from the Recoil of a Rifle.—Simpson (*Edinburgh Medical Journal*, June, 1891) reports the case of a man, thirty years old, in whom, after engaging in rifle practice, a transverse fracture of the right clavicle was found. Instead of holding the butt of the rifle close to his shoulder, he rested the upper end of the butt on the most prominent portion of the clavicle, so that in firing the whole force of the recoil came upon the clavicle.

Nitroglycerin for Asphyxia.—In a case of asphyxia from the inhalation of illuminating gas, Hoffmann (*Allgem. med. Ztg.*) succeeded in relieving the symptoms by the subcutaneous administration of nitroglycerin in doses of a hundredth of a grain. The injection was made in the precordial region, and was followed by marvellously prompt results.—*National Druggist.*

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, AUGUST 8, 1891.

THE BRITISH MEDICAL ASSOCIATION.

IT is with pleasure that THE NEWS presents to its readers to-day a partial report of the proceedings of the fifty-ninth annual meeting of the British Medical Association, held at Bournemouth, July 28th, 29th, 30th, and 31st. The magnitude of the meeting and the importance of its work are indicated by the large number of sections that participated, together with the enormous number of papers presented by a long array of names distinguished in every department of medicine. Emanating from a body having a membership of nearly fourteen thousand, these papers deserve the careful consideration of progressive men and women of the medical profession in all parts of the world.

That the American medical profession should have in its hands a report of the addresses made in the various sections, a little later than a week after their utterance, is a matter for sincere congratulation and is an evidence of the strong bond that unites the medical profession of the two greatest nations of the world, having in common more than a common language.

One cannot avoid being struck by the conservative tendency displayed in most of the principal papers, which stands out in contrast to the radical sentiment that pervades the medical thought of the day.

FATHER MOLLINGER.

THE interest in FATHER MOLLINGER, of Troy Hill, Pittsburg, concerning whom allusion was made in THE NEWS of June 27th, seems to have both abated and changed in character.

Concerning the reverend Father's personality, etc., we are permitted to quote the following from a private letter written by one of Pittsburg's best physicians:

" . . . in point of fact, FATHER MOLLINGER is like the regulation prophet in having more honor outside than inside his own bailiwick. I have a limited acquaintance with him. The man has an imposing presence, and a head that would make a study for an artist. A man of large and powerful frame, and the voice of Boanerges. Withal he is highly educated, ranking a fair knowledge of medicine among his accomplishments. In addition he has an innate love of the beautiful, and spends large sums in purchasing 'rich and rare' materials and objects and precious relics with which to decorate the chapel he has built, and which is perhaps unique in this country.

"FATHER MOLLINGER is a shrewd man, and I believe prescribes for almost all cases. The impression I formed of him was that he was not inclined to quackery, but that as a religious teacher he was bound to believe (with sincerity, I thought) that 'the prayer of faith will save the sick.'

"When you add to the influences I have alluded to, the fact that his advice was, ostensibly at least, gratuitous, it is not much wonder that his *clientèle* increased to considerable dimensions. But, after all, it was printer's ink that 'did the business.' As St. Anthony's Day (his patron saint) approached the number of pilgrims to 'Mount Troy' gradually swelled, chiefly I think owing to the persistent work of sensation-hunting reporters. When the great day passed there was a sudden collapse.

"As I have said, I think that several years ago FATHER MOLLINGER'S actions were unexceptionable from his point of view. As to his course more recently, I am inclined to think that (if one may compare small things with great) he has been going through a psychological experience something like that of Savonarola. He has been forced by the adulation—I might say, the adoration—of his devotees to do things which would seem to predicate the possession of miraculous power. For example, he would place his hands on the eyes of the incurably blind, or on the limbs of the hopelessly para-

lyzed, and go through some form of invocation, the unfortunate sufferer in the meantime momently expecting an exhibition of Divine power in his behalf. Of course, no miracles were performed, and of course, therefore, many who were devout believers are equally devout skeptics to-day."

Peculiarly interesting facts in reference to Father Mollinger are, that he was a regularly graduated and practising physician (in Germany) before becoming a priest, and that, together with the laying-on of hands and the invocation, he now gives medicines—of what kind does not appear—and that the patients send back for "renewals" from their distant homes.

The *Pittsburg Commercial Gazette* has been getting reports of the alleged cures, and, according to its correspondents and summaries, Father Mollinger's cases of cure are very difficult to find. Three cases were especially famous, but the patients could not be found at their supposed homes. In Nashville, Tenn., of the fifty or one hundred patients, "each one can tell of someone else who was cured, but when the one designated is found it is discovered that he or she is far from well." Several deaths are reported as following soon after the visits to Mount Troy, due undoubtedly to the strain, exhaustion, and excitement of the journey and its circumstances.

The *Pittsburg Medical Review*, in an excellent editorial comment, says:

"It is to be hoped there were some real cures of imaginary diseases and some imaginary cures of real diseases, to offset the great sacrifice those poor people had made in coming so far. The great majority were of the very poorest classes. They had invested their money as in a lottery, each hoping to be one of the very few who would depart sound again. Many must have been made worse by travel, which is never comfortable to the poor or the sick, as well as the discomforts of their stay in Pittsburg. After their return home they will miss the comforts which might have been had for the money thrown away on an illusory hope."

The history of the whole affair is provocative of serious and pathetic reflections, but its interest and value for physicians must still remain that which has already been pointed out: the power of the imagination and the will over morbid processes and weakened functions, and the capability of a dominant faith and a commanding personality to develop in the patient such volitional control and reaction.

SOCIETY PROCEEDINGS.

BRITISH MEDICAL ASSOCIATION.

Fifty-ninth Annual Meeting, held at Bournemouth, July 28, 29, 30, and 31, 1891.

First Day—July 28.

The President, J. Roberts Thomson, M.D., F.R.C.P., delivered an "Address of Welcome." He discussed the climatological advantages of Bournemouth, but devoted himself especially to the subject of sanitary legislation.

Second Day—July 29.

T. Lauder Brunton, M.D., D.Sc. Edin., LL.D. Aber., F.R.C.P., F.R.S., delivered the "Address in Medicine," in which he took up the changes in the medical profession in the last twenty-five years.

He noted that a great increase had occurred in the knowledge of the nature, causation, and treatment of diseases, and a greater gain in the general adoption of the experimental method by which most of our recent knowledge has been acquired, and from which we may hope even greater advantages in the future. There is also a corresponding alteration in the teaching of medicine, in that instruction is practical instead of theoretical.

He referred to the profound influence that the doctrine of evolution had exerted upon medicine, as a subdivision of biology. As to the changes that had taken place in medical students he stated that there is no other class in which one can find so many gentlemanly, thoroughly well-educated and hard-working men. The struggle for professional existence has become a severe one. Its cause is to be found in the excessive number of men who have been entering the profession notwithstanding the barriers raised by the entrance examination; for this very barrier, by raising the quality of the men, has naturally raised the estimation in which the profession is held, and has, therefore, made it more attractive. But the excessive severity of the struggle, on the other hand, has a tendency again to lower the profession by rendering it so difficult for medical men to make a bare living that they are sometimes tempted to think more of their fees than of the welfare of their patients, and occasionally to resort to such means of making money as tend to bring discredit both on themselves and on the profession to which they belong.

Long ago the doctor's means of diagnosis consisted in inspecting the tongue, feeling the skin, counting the pulse, shaking the urine, and looking at the motions and the sputum. But now, in addition to a thorough training in auscultation and percussion, students have to learn the use of the laryngoscope, ophthalmoscope, and otoscope, and the application of electricity. They have to acquire a knowledge of the chemistry of the urine and its alterations in disease, and, what takes still more time, they have to learn the microscopical appearances, not only of the tissues and excretions in health, but their alterations in disease, and must be acquainted with the methods of staining so as to detect tubercle-bacilli and other disease germs.

Increased knowledge of diagnosis has led to an apparent change in the mortality of different diseases. Thus, the frequency of death from heart disease appears to be much greater and that from apoplexy much

smaller now than fifty years ago. In all probability this difference is not real, but only apparent, and is due to the more accurate diagnosis by which the presence of cardiac disease is now ascertained. The supposed increase in the frequency of carcinoma is probably in great measure due to a similar cause; for it is probable that many cases which were formerly classed as chronic diarrhea, dysentery, jaundice, or dropsy, depended upon malignant disease, while others probably depended upon unrecognized disease of the kidney, for until recently little attention was paid to the condition of the urine.

But real changes, as well as apparent ones, have occurred in diseases. Some have become more frequent and others are rarer. Thus, typhoid fever is almost certainly more common, because the increase of our sewage system has given greater facilities for its spread. Typhus fever, on the other hand, has become comparatively rare. Pyemia is another disease which, although not totally extinct, is very greatly lessened in virulence.

The departments in which the greatest advances have been made within the last five-and-twenty years are those of fevers and diseases of the nervous system. A new era in the study of the latter was foreshadowed by the experiments of Fritsch and Hitzig on the brain of the dog, but it can only be said to have fairly begun with Ferrier's localization in the brain of monkeys of the cortical centers, both motor and sensory, for the brain of the dog was too unlike that of man for experiments upon it to be of much practical use in the diagnosis of human ailments, while the likeness in the brain of the monkey to that of man at once allowed conclusions drawn from the experiments upon the former to be transferred to the latter. Yet if we try to describe in one word the department in which medicine has made the greatest progress within the last quarter of a century, that word must be "fevers;" for during this time we have learned to recognize fever by the use of the thermometer in a way we never did before; we have learned the dependence of the febrile process in the great majority of cases upon the presence of microbes in the organism, and we have become acquainted with an immense number of chemical substances that have the power both to destroy the microbes and to regulate the febrile process.

Though previously used, it is only within the last five-and-twenty years that the use of the thermometer has become at all general. The constant employment of the instrument shows when the temperature of a patient is rising so high as to be dangerous, and affords an opportunity for the use of antithermic measures, such as cradling, cold sponging, cold affusion, cold baths, or by the administration of antipyretic remedies.

The thermometer has not only enabled us to detect the onset and to watch the progress of fever, but in conjunction with microscopical research, physiological experiment and chemical analysis it has enabled us to gain a fuller knowledge of the nature of the febrile process itself. We know that during it the organism is consuming rapidly, like a candle burning at both ends. We have learned also, to a great extent, the necessity for the elimination of the waste products, or ashes, as we may term them, which the excessive combustion produces, and thus we know why the surgeon is so anxious regarding the result of an operation when the kidneys of his patient are inadequate. For if any febrile attack following the operation should lead to increased demands upon these secreting powers, they might fail to meet it, and the retained excreta would poison the patient.

The rapid increase in our knowledge has been due not merely to the constant use of old methods, but to the introduction of new ones. The greatly increased powers of the microscope and the better methods of illumination have been of the greatest service, but their utility would be very much less than it is had it not been for the general introduction of the microtome and the invention of new methods of staining. The facility with which sections are made by it has made microscopical research much less tedious, and has enabled trained histologists to do more work in a given time, and medical students to acquire knowledge more rapidly. But without the method of staining introduced by Weigert and Ehrlich, we should, even with the best microscopes, be unable to recognize most of the microbes that are so important in the causation of disease.

From the cupidity of the Spaniards, which led them to cut down the cinchona trees of the Andes in order to fill their pockets with the gold they received in exchange for the precious bark, while their stupidity prevented them from planting new trees to replace those which they felled, quinine became so dear that attempts were made to produce it artificially. These were unsuccessful, but out of them came the discovery of the anilin dyes, so useful in histologic and bacteriologic study, and the other antipyretics, salicylic acid, acetanilide, antipyrin, phenacetin, etc.

From a study of the factors responsible for the variability in crystalline form of tartaric acid, Pasteur was led to look to life and to living beings as the source of asymmetry. He tried to produce this asymmetry in salts of tartaric acid by fermentation, and found that during the process an organism developed that eats up the dextro-tartaric acid, and leaves the lavo-tartaric acid behind. This led him to investigate such minute organisms, and, by simplifying the soil in which they grew, and separating the organisms one from another, he learned the conditions of their growth, and showed that most processes of fermentation were due to the presence of living organisms.

Fermentation is dependent upon both chemical and biological activity, respectively. Thus diastase is not a living organism, while yeast is essentially vital. Living organisms may, however, be active by the development of chemical ferments, which may be effective (in lesser degree) in the absence of the organisms.

Pasteur next established the dependence of the silkworm disease and of anthrax upon the presence of specific microbes which could be transmitted and communicate the disease, and by destroying the infected eggs of the silkworm he eradicated the disease and restored the silk-industry to France.

He also found that the germ of anthrax could be cultivated outside the living body and grown in flasks under varying conditions, some of which were favorable and others unfavorable to its growth. High temperature enfeebled the virus, so that it no longer killed an animal with the same certainty, and by inoculating first with a weak virus and then with one successively stronger and stronger, he found that animals could be completely protected either from inoculation by the strongest virus

or by infection from other animals suffering from the actual disease.

Another extraordinary fact which he made out was that the virus, thus weakened so that it will not kill a guinea-pig a year old and still less a sheep or ox, may again be rendered most potent by inoculating a feeble animal, such as a guinea-pig a day or two old, and, from this, older and stronger guinea-pigs, the strength of the disease-germs increasing with every inoculation, until finally sheep and cows may be killed by it. We can thus see how an epidemic of disease beginning sporadically and attacking weak individuals may gradually acquire such strength as to carry off the strongest.

The next step in progress was Koch's utilization of transparent gelatin as a culture medium. It thus became possible, from day to day, to study the growth of the germs and to make pure cultures. In this way it became possible to study the life-history of the organism, the influence of soil, temperature, moisture, and other influences upon its growth, and the effect of one organism upon another, when both are grown together. Thus it was found that certain germs were not compatible with one another, while others rendered the soil favorable for the development of still others. Then there is also a conflict between germs and cells that is apt to be influenced by external conditions. In this may be included the phenomenon of phagocytosis.

This process of phagocytosis is now regarded by many as only a small part of the struggle between an organism and a microbe, but it is impossible to see one part of a microbe half-digested by the cell in which it is imbedded, while the outside half remains unaltered, without believing that the process is one of great importance. At the same time, it seems that the process of phagocytosis, where the microbe and the cells meet in close conflict, bears about the same relationship to the total struggle that a bayonet-charge bears to a modern battle. The main part of the fight is really carried on at some distance by deadly weapons, by bullets in the case of the soldier, and by ferments, poisonous albumoses, and alkaloids on the part of the cells and the microbes.

In the last few years increasing attention has been paid to chemical investigation of the ferments and poisons produced by microbes.

It is now possible to separate the albumoses and poisons from the microbes which produce them, either by filtration or by destroying the microbes by graduated heat; for, as a rule, they are destroyed by a lower temperature than the albumose or poisons which they form.

As the albumoses produced by microbes are nearly allied, chemically and physiologically, to those formed in the alimentary canal of the higher animals by digestive ferments, it is natural to suppose that microbes, like the higher animals, split up proteids, starches, and sugars by enzymes, which they secrete, and which in both cases may be obtained apart from the living organisms which produce them; that, in fact, we should be able to isolate from microbes bodies which correspond to pepsin or trypsin, just as we can isolate these from the stomach or pancreas of an animal. In some, although not in all cases, this attempt has succeeded.[1]

[1] *Vide* Brunton and Macfadyen, Croonian Lectures on Chemical Structure and Physiological Action, British Medical Journal, June 15, 1889, p. 1336.

The albumoses produced by microbes resemble those formed during normal digestion in being poisonous when injected directly into the circulation, although they may not be so greatly absorbed from the intestinal canal. One of the most remarkable discoveries in regard to albuminous bodies is the fact that some of them which are perfectly innocuous, and, indeed, probably advantageous to the organism in their own place, become most deadly poisons when they get out of it.

It is possible that one form of albumose may neutralize the action of another, thus rendering both innocuous, while either alone may be a deadly poison.

Perhaps a similar process of splitting up and recombination may explain the formation and disappearance of the enzymes, such as pepsin and trypsin, by which digestion is carried on. The pancreas of a fasting animal will not digest albuminous bodies like fibrin, while the pancreas of an animal killed during full digestion will do so rapidly. Yet the fasting pancreas contains the zymogen, or mother-substance, which yields the digestive ferment, and, as Kühne has shown, by treating it first with acid and then with alkali, it becomes active. Lépine has lately shown that while the pancreas is pouring into the digestive canal a ferment that will form sugar, it is at the same time pouring into the circulation another ferment that will destroy sugar.

Immunity is probably a complex condition, not dependent upon any single factor. If a microbe has gained an entrance into an organism, and produces a proteid or an albumose poisonous to the organism which it enters, it may grow, thrive, and destroy that organism, while the injection of some other proteid that would neutralize the poison might save the animal while the microbe would perish.

Hankin has found that while a mouse inoculated with anthrax will die within twenty-four hours, a rat resists the poison altogether; but if the mouse, after being inoculated with the disease, has a few drops of rat's serum injected into it, instead of dying, as it otherwise certainly would, it survives just like the rat; from the spleen of the rat Hankin has isolated a proteid that has a protective action similar to that of the serum.

Injections of goats' blood and of the serum of dogs' and of goats' blood have been applied to the treatment of tuberculosis.

It is possible that the good derived from blisters is dependent not only upon an influence exerted upon the circulation, but also upon a sort of endermatic administration of proteid matters derived, no doubt from the blood, but altered in their passage from the vessels to the surface of the skin, so as to have an effect upon the body entirely different than if they had remained in their ordinary place.

It is possible, too, that the good effects of bleeding may be due to a similar cause. Experiments upon animals have shown that withdrawal of blood from the veins causes absorption of proteid matters from the tissues, and these may have an action of their own upon the blood and tissues generally with which they are thus brought into contact. Indeed it is possible that free purgation may act in the same way.

Paré rendered surgery a great service when he prescribed the application of ointments to wounds; but Lister rendered a greater when he recognized that the

danger of operations was due to the entrance of germs and, by preventing this, he has completely revolutionized surgical practice; nay, more, he has, to a great extent, revolutionized medicine, for the diseases of the internal organs that were formerly entirely under the physician's care are now becoming amenable to surgical treatment, and diseases of the stomach, intestine, liver, kidney, and lungs, and even of the brain and spinal cord, are now successfully treated by surgery when medicines are powerless to help.

Not only in surgery, but also in infectious disease, has the recognition of disease germs as a source of danger to the organism led to their destruction outside the body and insured safety from their attack.

So long as people were ignorant of the causes of epidemic diseases, they were utterly unable to combat them; but once an epidemic is known to depend upon the presence of a certain organism, precautions can be taken for destroying the organism outside the body by means of disinfectants, or by inoculation lessening the susceptibility of the organism to its ravages inside the body, or combating its effects by means of antipyretics.

In comparing the drugs at our disposal now with those we possessed twenty-five years ago, we are at once struck by two facts, namely, that we not only have a very much larger number of powerful remedies than before, but that we also know better how to use the old ones. Both of these gains we owe to experimental pharmacology, to the testing of drugs upon the lower animals.

Every now and again a loud outcry is raised against vivisection, partly from ignorance and partly from prejudice. Many—probably most of those opposed to experiments on animals—are good, honest, kind-hearted people, who mean well, but either forget that man has rights against animals as well as animals against man, or are misled by the false statements of the other class. These—namely, those who, blinded by prejudice, regard human life and human suffering as of small importance compared with those of animals, who deny that a man is better than many sparrows, and who, to the question that was put of old, "How much, then, is a man better than a sheep?" would return the reply, "He is no better at all"—such people bring unfounded charges of cruelty against those who are striving, to the best of their ability, to lessen the pains of disease both in man and also in animals.

To experimental investigation in animals we owe, in addition to other valuable information, in great measure, our power to lower temperature, for to it is due not only the introduction of new antipyretics such as salicylate of soda, antipyrin, antifebrin, and phenacetin, but the extension of the use of quinine from a particular kind of fever—malaria—to other febrile conditions.

Perhaps the most promising thing about pharmacology is that we are now just beginning to gain such a knowledge of the relationship between chemical structure and physiological action that we can, to a certain extent, predict the action of a drug from its chemical structure, and are able to produce new chemical compounds having a general action such as we desire—for example, anesthetics, soporifics, antipyretics, and analgesics.

But the excessively rapid development of medicine and medical science requires that those who are entering the profession should not only be taught the things that we know now, but should be so trained as to enable them to keep more or less abreast of medical progress. This can only be done by giving them a thorough grounding in chemistry, physiology, general pathology, and pharmacology; and this training must be essentially of a practical nature, not only in the way of demonstrations, but of actual work on the part of the student himself.

The Section of Surgery.

John Ward Cousins, M.B. Lond., F.R.C.S., delivered an address on "Recent Advances in the Treatment of Tuberculous Diseases of the Joints." After considering the historical aspect of tuberculosis of the joints, he briefly discussed the old pathology of tubercle and the relation of the scrofulous diathesis to tuberculosis. The modern pathology of the disease was then taken up and the subject of hereditary transmission considered. It was held that, as during the early stages of joint-disease the morbid action is often localized, arrest is at least possible. There can be no reason why a joint or a bone should not recover, and the tuberculous infiltration subside and ultimately shrivel into a fibrous scar just like a similar deposit in the apex of a lung.

Expectant treatment can be carried out under favorable circumstances, combining rest and protection of the limb with fresh air and exercise. By the use of suitable apparatus, injury can be avoided, while the necessary rest is secured.

Tuberculin has yielded unsatisfactory results.

In some cases, early operative interference has done good.

Whenever the indications for surgical interference are clear, early operation must be attended with many advantages. The risk of delay is always in proportion to the progressive and obstinate character of the disease, and timely aid will often prevent its extension, and at the same time deliver the patient from the danger of deep infection and the development of secondary tuberculous centers. The only hope of cure must depend upon the complete removal of the diseased tissue, and the facility with which this can be accomplished rests entirely upon the extent of the local mischief. The preservation, too, of useful mobility in the joint may be anticipated when the morbid process is well localized, so that the manipulation involves only a limited excision of the synovial membrane and a partial division of the fibrous capsule.

For the successful performance of a partial arthrectomy there must be clear evidence of a localized deposit. In some cases, children have exhibited very little pain or lameness, but the joint has been in some part swollen, with the capsule thickened and the bones enlarged, but without any indication of softening or suppuration. By a well-directed operation, near the neck of the femur or the head of the tibia, search has been made for a spot of tuberculous infiltration, with the result that a carious cavity has been found and small sequestra successfully removed.

Another recommendation for early arthrectomy is the little danger that attends the operation. With ordinary surgical precautions the risk may be fairly considered trifling, even when a portion of bone has to be resected. After a full incision in the most convenient position for exploration and carefully defining the disease, the infil-

trated tissue must be excised with the scissors or cutting spoon, and the cavity thoroughly flushed with hot water. To insure rapid union, the surface should then be dried and the wound closed with deep and superficial sutures. The limb must be kept at rest until the healing process is complete.

The articular cartilages are seldom the seat of primary disease, for as a general rule the morbid process has its origin either in the synovial structure or the articular extremity of the bone. When the osseous tissue is the seat of a tuberculous infiltration, the evidence of its existence is often wanting until softening occurs in it and inflammatory reaction takes place. As soon as these infective changes reach the synovial membrane they extend to all the structures of the joint. Sometimes they make their way through the superficial cancelli to the outer layer of the bone, and then superficial caries and slow suppuration are the result. At another time the morbid process advances in the direction of the articular cartilage, softening and erosion of this structure follow, and then inflammatory changes which, unless checked by surgical treatment, issue in chronic abscess, caries of bone, imperfect arrest of the disease, and finally ankylosis. Now in all these forms of advancing tuberculous disease, surgery offers the only scientific method of treatment, and we can safely repeat our incisions, scoopings, scrapings, and cleanings until the disorder is eradicated and a useful joint preserved. But instead of a slow disorganization, the tuberculous center may be suddenly discharged into the capsule, diffusing the infective material over the whole synovial surface, and kindling suppurative inflammation with great rapidity

In the performance of complete arthrectomy in more advanced cases in which the morbid process is too extensive for any partial operation, a free division of the ligaments and capsule is necessary for the exploration of all the recesses of the articulation, and the excision of deep infiltrations of the synovial and osseous structures, so that the preservation of only a limited mobility must be anticipated. The whole of the pulpy granulation-tissue must be dissected off, and the ligaments and cartilages carefully scraped. It is absolutely necessary to remove every particle of the diseased synovial membrane, and all tuberculous foci in the bones must also be cleanly cut out with the gouge. Care must be taken to prevent any remnants of the infective tissue being left behind on the raw surfaces, and the accidental re-inoculation of the disease through the medium of the fresh incisions. The method of flushing with hot water the seat of operation is the best way of carrying out these important precautions. The operation of arthrectomy of the hip can be readily performed by the anterior and vertical incision and division of the neck of the femur with the saw, and then the excision of the infiltrated tissues. After a simple protective treatment for a few weeks, and the application of a Thomas splint during convalescence, the results are often very satisfactory.

In performing complete arthrectomy of the knee-joint, the old horseshoe incision and an oblique division of the ligamentum patellæ constitute a better method than any other for obtaining free access to the interior of the cavity. The practice of lifting up the tuberosity of the tibia, instead of division of the tendon, may be found very useful in some cases. It is important to carefully clean the lateral and crucial ligaments, and to avoid damaging the cartilages and articulating surfaces. Sometimes carious bone outside the capsule of the joint can be removed with the gouge. It must always be our object to secure the complete extirpation of the diseased structures, and to preserve as far as possible the mobility of the articulation. Fortunately, the limb is not shortened, and the development of the bones is scarcely impaired. The articulating surfaces are in a great measure preserved, and the operation, when compared with resection of the joint, is attended with less risk of life.

Complete resection at once is to be preferred in all cases with old sinuses and the carious remnants of old infiltrations. The joint is freely opened, and as thin a layer of bone as possible is removed from all the articulating surfaces. The gouge is used for cleaning out any infiltrations, and then the patella is divided vertically with the saw. After cleaning every recess in the capsule, the bones are jammed together as tightly as possible, the periosteum is carefully sutured, and the wound closed, except at the extreme ends of the incision.

Conservative surgery in the advanced stages of the disease is not to be advocated, not from the dread of deepening the general and local infection from re-inoculation through the seat of operation, but rather from the feebleness of the vital power, which has been slowly undermined by prolonged suffering and suppuration. The intensity of the disease has been quickened by a chronic septic condition of the system, and it is the danger of its sudden aggravation, even with every possible precaution, which adds to the risk of surgical interference. The microörganisms of septicemia, or their poisonous products, exert a marked influence over the course of tuberculosis, for their presence reduces the resisting power of the system, and helps on the local and constitutional spread of the disease.

But it is not only septic infection in its various forms that we have to combat, but every other kind of acute disorder of the blood. Children especially are liable to be attacked with any of the infectious fevers; and these are all attended with peculiar risks. Measles, from its disturbing influence over nutrition, is prominent among the group, for its power of rekindling tuberculous inflammation.

Occasionally, however, experience has seemed to point in the opposite direction, and an accidental blood-storm has exercised a remarkable effect on the course of the malady.

Now, notwithstanding the risk of late operations, exceptions occasionally occur in practice when interference appears to be the better course. There are certainly cases of chronic tuberculous joint-disease marked by secondary centers and general infection, and even aggravated by a chronic septic condition of the system, in which the vitality of the tissues and the residue of constitutional vigor appear sufficient to warrant an effort in the direction of conservative surgery.

The Section of Obstetrics

was opened with an address by William J. Smyly, M.D. He maintained that gynecology and obstetrics are so intimately related that it is at times difficult to distinguish the line of separation. He cited a number of cases from practice illustrative of his view.

He would not deny to any man the right to limit his practice as he might see fit; but he maintained that, in teaching, gynecology must not be separated from midwifery; this isolation places such difficulties in the way of students, that practical midwifery is not efficiently taught, and the study of gynecology is more or less optional. Clinical teaching can be efficiently carried out only in the wards of a hospital, where too a limited material can be utilized in teaching a number of pupils.

Another important matter is accurate clinical observation, and this can only be carried out in hospitals. It was from observing the comparative mortality in two lying-in hospitals that the cause of puerperal fever was discovered and its prophylaxis pointed out. Puerperal fever is a preventible disease.

In conclusion he gave an account of a septic outbreak that occurred in the Rotunda Hospital, and of the measures taken to eradicate the disease. A patient was permitted to be examined abdominally by any number of students, but vaginally by three only and one pupil midwife. Previously to examination, the external genitals were carefully washed with soap and water, irrigated with plain water, and finally bathed with corrosive sublimate solution, 1 in 500. The examiners' hands were thoroughly cleansed with soap and water and a good nail-brush, the soap removed by carbolic lotion, then the hands washed in sublimate solution. A patient in whom premature labor was induced died of acute septicemia. Subsequently a number of cases presented considerable elevation of temperature. In consequence, vaginal examinations were temporarily abstained from. The temperature was still abnormally high in some instances. Analysis showed that, to avoid infection by the nurse, each patient washed herself. This was changed, and the dressing was done by the nurse with antiseptic lotions. Matters now improved. No unusual elevation of temperature and no further death occurred.

The Section of Psychology

was opened with an address by P. Maury Deas, M.B. London. He devoted himself to a consideration of lunacy-legislation in England, pointing out its defects and inconveniences, and indicating the lines along which reforms may be instituted.

The Section of Pathology

was opened with an address "On the Uses and Prospects of Pathology," by W. Howship Dickinson, M.D.

In times not very remote, little was known of pathology but rough morbid anatomy, and very little of that. Large morbid anatomy has advanced so much, especially during the last hundred years, that it may be believed that there are few changes obvious to the naked eye which have escaped notice. Rough morbid anatomy is the groundwork of medicine, and must ever be essential to the physician as presenting results in a compendious form.

Of the more substantial organs, we probably know something which, though rough, cannot be altogether wrong. Within the last half-century the minute morbid anatomy of the nervous system has been begun, and some lines of light, however dim and narrow, projected into places dark since the creation. Diseases once thought to be functional or without organic change have been provided, some, like essential paralysis, chorea, and diabetes mellitus, with something of morbid anatomy, however incomplete; while others, like tetanus and the paralysis of Landry, have been suspected, if not convicted, of being connected with poisons which, though less visible, are not less material.

The subject of embolism was briefly referred to, and that of suppuration taken up.

The loss of leucocytes, under the name of pus-corpuscles, explains the relation of blood and pus—hitherto a mystery; and the lardaceous deposit as a consequence gives a morbid interest in what is left.

In the past, many diseases have been attributed to either too much oxygen or too little, which was considered with too little regard to the vital action of the organism. The chemical school saw in inflammation only excess of oxidation or combustion, which may truly exist, and of which the increase of temperature may be a result; but it took too little account of what may be antecedent to this in tissue and vessel. In diabetes it saw little more than a deficiency of oxidation, which indeed there may be, but which must be secondary to changes in organic structure which as yet we have seen but imperfectly.

With regard to gout and uric acid as products of suboxidation, the chemists have reached results seeming to embrace the truth less incompletely, though even now there is probably something to learn of organic lesion or disturbance outside the domain of pure chemistry. We know something of hepatic disturbance in connection with uric acid. What more will be added, and to what organs and tissues it will relate, is work for the future.

Hemoglobinuria is closely allied to the symmetrical gangrene of Raynaud, and is associated with localized lividity of the skin. It is held that this lividity is due to the cutting off of the arterial current and the oxygen which belongs to it by vascular spasm, and the destruction of corpuscles is due to the carbonic acid in the parts from which the oxygen is then shut off. If this view is correct, we have a result of suboxidation which deserves a prominent place in chemical pathology.

A disease that presents itself as of chemical origin is scurvy. The conditions that give rise to sea-scurvy are generally known. It is not probably as widely recognized that scorbutic affections are common on shore—among infants brought up by hand. It is to be attributed to the substitution for fresh milk of various artificial preparations. Not that these preparations are in themselves injurious, but they are insufficient.

Milk in its fresh state, and of good quality, whether from biped or quadruped, is antiscorbutic. What fresh milk contains that is so essential and so difficult to preserve, we do not know.

So many disorders have been shown to have foreign organisms associated with them, that we may be sure that before long many more will be in the same position. But if we find a microörganism for each disease, the question may still remain, What is the relationship between the two?

Outside the microörganisms is a pathological system which, though we recognize its existence and its importance, we understand but imperfectly. If the present rate of progress is maintained, we must be on the eve of discoveries in the physiology of disease which can scarcely fail to be of transcendent importance.

The study of the bacillus has given us antiseptic surgery; the study of its products may lead to we know not what in medicine, whether preventive or curative. Old truths grow and new ones gather around them. Jenner's vaccination may prove but the prelude to many similar modes of prevention. Immunity from anthrax and from hydrophobia can be brought about by the introduction of a harmless dose of a poison that in large quantity or a more active form is deadly. Why should not tuberculosis be prevented in a similar manner?

The influence of pathology, that is, of the habitual consideration of the nature and results of disease, has hitherto been to confer that most extensive of all knowledge—a knowledge of what we cannot do. A study of the results of disease and of its natural laws is a continual warning against the superficial fussiness of the shallow practitioner, who claps on here a poultice and there a blister, and somewhere else rubs in an embrocation assiduously, with a greater faith in the penetrating effects of such applications than knowledge of the profound nature of disease. Pathology teaches humility.

Such is the present position; but who can say what is before us? Pathological discoveries which revolutionize our knowledge of the nature of disease are not likely long to remain without practical results in the cure or prevention of it. In the conflict between man and the bacterium, between the highest of animals and the lowest of vegetables, it must be allowed that so far the vegetable has the best of it; but though the more vulnerable the animal is the more inventive, and it may happen in the future as it has in the past that science will prevail against numbers. Bacteriology is in its infancy, but it is gigantic, at least in possibility. To isolate the organic germs of tubercle, leprosy and other diseases which have similar pathological associations may be but the first step toward results which may prove to be of importance to humanity beyond all politics, beyond all conquest, beyond all the appliances which minister to ease, comfort and luxury.

Reference was made to what may be called the geography of pathology, the effects of climatic and other local influences in promoting and preventing morbid processes. Of local influences, though we know comparatively little, yet we know enough to suggest that of the means under our command of modifying chronic disease, change of place is the most important. To know that there is little stone in Ireland and much in Norfolk, little in the western counties, much in the eastern; that while in England it is most frequent in the colder parts, it is so prevalent in India that lithotomy has long been a native accomplishment; to discern the laws which underlie these facts, as we can partially do, cannot fail to throw light on the origin of the disease and help in its preventing.

The frequency and severity of diabetes in some parts of India and Ceylon cannot but suggest the influence of an opposite climate in its amelioration. If scorbutic affections are invited by cold, presumably by way of tissue waste and oxidations, what will be the result of the same agency upon the uric acid diathesis, gout and the disorders in which oxidation is wanting? It might be better to shudder in the frigid zone than to suffer arthritic tyranny in the temperate.

The infrequency of the granular kidney as originating in subtropical districts has already had its influence in the treatment of the disease. Let us know what diseases are promoted and what are prohibited by the *genus loci*; let us take the great forces of external Nature into our confidence and we shall be able to control disease by greater agencies than the druggist can supply.

The Section of Ophthalmology

was opened with an address by N. C. Macnamara, F.R.C.S.

The treatment of immature cataracts was first taken up. Immature cataracts are usually not operated on from a fear that a portion of the cortex of the lens will be left in the anterior chamber of the eye, and will probably excite inflammation of the iris, with its consequences. Inflammation of the iris, however, does not necessarily result from the presence of aseptic cortical matter in the anterior chamber after the operation of extraction. In every such proceeding, the eye should be kept absolutely free of septic matter, and by far the larger portion of the lens, even in immature cataracts, being removed, that which remains cannot well exercise injurious pressure upon the angle of the anterior chamber. The operation of extraction is successful in proportion to the completeness with which the lens and the capsule are removed.

If the conclusion is reached that there is no special reason why an immature cataract should not be extracted, the great advantage to be derived from such a proceeding, in cases of advancing cataracts in both eyes, is self-evident.

It is a mistake to condemn a patient suffering from cataracts in both eyes to wait for an operation until the cataract in one eye has become matured. The results following the extraction of immature cataracts are on the whole more favorable than those of fully formed cataracts, because in the former the lens escapes from the eye with less damage to surrounding structures than it does when a large, hard cataract has to be extracted, provided that a sufficiently large opening is made in the cornea to allow the lens to pass through it with ease, that an iridectomy is performed, and this best at the time of extraction. After rupturing the capsule of the lens, gentle and continued pressure with the curette must be made upon the lower portion of the cornea, the curette following up the lens as it passes outward through the section made in the cornea.

Among the upper classes, especially in those over sixty-five years of age, it is safer, having first applied a solution of cocaine to the eye, to get a thoroughly competent person to administer an anesthetic to the patient before operating. If an anesthetic is administered the eyelids should, after the operation, be smeared with an ointment of vaselin and iodoform, and a carefully adjusted pad of antiseptic wool applied over the eye with a linen bandage, to keep some pressure on the eye for twelve hours, or until all inclination to sickness has passed away, when a light cotton pad and elastic bandage should be substituted for the first dressings. Unless symptoms arise indicating the use of atropine, eserine, or cocaine, these drugs are never used after the operation for extraction. The patient can sit up on the third day after the operation, but the greater the care taken, for at least a fortnight, the better will be the result.

Based upon the conception of glaucoma as dependent upon either some mechanical obstruction to the escape

of fluid through the lymphatic system of the eye, or to an excessive secretion of lymph within the globe of the eye, a relation was traced between hypermetropia, hypertrophy of the ciliary muscle, with an augmented supply of blood, serous effusion, and pathological changes in the lymphatic apparatus of the eye.

Exceptionally glaucoma develops in patients with flat corneæ and shallow anterior chambers. Not only does the angle of the anterior chamber differ in form from that of the normal eye, but the hypermetropia is apt to lead to pathological changes in the tissues constituting the ciliary body, and so to impaired circulation of lymph in the eye, and to faulty innervation of the iris; the pupil, therefore, acts imperfectly, and remains somewhat dilated. Given these conditions, if from any exhausting cause the contractile fibers of the iris are still further relaxed, and the pupil becomes widely dilated, the iris shrinks upon its attachments, and so tends further to obstruct the already embarrassed lymphatic circulation through the ciliary body. In these circumstances an attack of acute glaucoma may occur at any moment, and be as quickly relieved by the application of eserine to the eye, which, as the pupil contracts, draws the iris from the angle of the anterior chamber, and so frees the spaces of Fontana and the passage of lymph from the eye.

The glaucomatous symptoms may be prevented by making the patient *constantly* wear proper glasses, and applying eserine to the eye once or twice a week if the pupil is inclined to remain dilated or the patient has a tendency to increased intraocular tension. The object is to give the ciliary muscle rest, and to keep the pupil contracted.

Four cases of double optic neuritis, developed in the course of influenza, were reported.

In one the appearances were those of intense papillitis, with numerous hemorrhages into the retina, and consecutive atrophy, with blindness. The other three were instances of uncomplicated papillitis with great impairment of vision; the discs in all three gradually cleared, and the patients regained perfect vision.

The Section for Diseases of Children

was opened with an address by JAMES GOODHART, M.D., F.R.C.P.

He objected to the word pediatrics, insisting that the members of the Section were not specialists. He deplored the relegation of a study of constitution and predisposition to a place secondary to microbic influence. He characterized as the specialism of specialism the tendency that sends a woman to a gynecologist for one condition; to an obstetrician for another; to a medical man for a third; that takes her to one specialist for her baby, and to another for an older child.

The child is father to the man. The diseases of children are as the early eruption upon the skin is to the mature affection, and they must be studied, not only as they are seen, but in the light of what they will become; they are an embryonic stage; but they *are* the mature disease modified only by the physiological conditions and activities existing at the time. Disease as it manifests itself at one time and at another does but complete the picture of the one disease, and some are children in some respects to old age, while others, though being yet young, have known no childhood.

Though not recognized as one of the diseases of childhood, gout does occasionally appear in that period, and is not to be discriminated from acute rheumatism; it attacks the larger joints; is attended with free sweating; it certainly attacks the heart, and is also relieved by the salicylates. It may be said, of course, that this is all acute rheumatism. So be it. But if so, we must say that, under some circumstances or at one period of its life, gout is acute rheumatism—a very important fact in the history of the two diseases, if it be true.

It was brought out that excessive excretion of uric acid in the urine was in children, as well as in adults, dependent not only upon a diet rich in meat but also upon a diet largely farinaceous. Renal colic is far commoner in children than is usually supposed, but it passes for stomach-ache pure and simple, and goes unrecognized.

Some children habitually pass a urine of abnormal concentration, in which albumin may occasionally appear; it seems worth consideration whether such a condition may not foreshadow a risk of the supervention of granular kidney.

The shape of the head in children, suggests the future of the man, and tells of the functions of the brain itself. Observation has demonstrated that the frontal lobes of the brain may suffer serious injury with disproportionately insignificant sequelæ in children, as well as in adults. It appears that, a head with an ill-developed and small frontal segment is indicative of the existence of a brain. that will, if sought for, give evidence of some want of balance or control. Such a brain is likely to take on the epileptic habit; it is a brain that slight provocatives stir to frenzy; it is likely to be cunning; it is likely, as time goes on, to exhibit one or the other of the common vices of nervous action—to be intensely self-conscious, or painful; to be impulsively incoherent in its action; to be mad; or worse, criminal. It seems as if the whole order of being is enwrapped in the frontal lobes.

In such children the nervous capital is small; they consequently need to have chosen for them the best investments.

Some children display a special tendency to boils; while erysipelas in childhood presents a contrast with its occurrence later in life, being, in the one, uncommon, prone to be migratory, of indefinite duration and almost invariably fatal; in the other, frequent and transitory. Epistaxis is peculiar to childhood; so is a curious condition of the pupil that is sometimes widely dilated and temporarily insensitive to even the strongest light, but the light removed, the iris immediately acts.

Intussusception is an ailment allied to this in the sense that it is a disorder of an involuntary muscle which may not be the mere accident it is often supposed to be.

Again, what does that common condition, the frequent passage of pale feces mean? Clothed in the garb of the veriest commonplace it is a most important matter, for there are few greater sources of anxiety. A symptom of this kind may mean anything—a disproportionate quantity of milk food, for instance—and unquestionably, in some cases, such as cholera infantum, it is due to suppression of bile.

The interest of these cases lies in what they foretell for the man and woman of the future, for such children, unless wisely treated, develop into the dyspeptic, the morbidly sensitive, the depressed, the neuralgic, the physic-swallower, the patent medicine machine, in short,

the ignoble army of the self-martyred, who think they are liverish and are not; who can tell every detail of the daily variation of their uncomely functions, but of weightier matters, such as the happiness they get out of life, the happiness they impart to life, their objective relations to the world in which they were born to take a part, they have nothing to say or to think.

There is, however, another disease that is considerably illuminated by attempting to trace it back from adult age to childhood—spasmodic asthma. Asthma is never seen as such in babies. If it does not occur as *asthma* it has a representative in an exceedingly common ailment. From babyhood upwards, but less commonly as the child grows older, to be about seven or eight years old—about the age when spasmodic asthma begins to appear, although it cannot be said to be common even at so early an age as that—certain children and certain families are prone to sudden attacks of what is apparently acute pulmonary catarrh. Some of these cases are supposed to be due to chill. The child is therefore watched with the most vigilant care; it is packed in many additional layers of clothing; it is swathed in shawls and neck apparel; it is closely shielded from every breath of air. For a bath a lick and a promise suffice, but the child still catches cold with ever-increasing readiness. It may be thought that the pulmonary disturbance is all due to the *stomach*, and there is less difficulty in establishing a more reasonable probability of an origin of this kind. The child is dieted with the most scrupulous care, and yet the attacks recur. They may be a little milder or less frequent, but the improvement is slight. It is certain that this class of cases is not in the main due either to chills or to indigestion, although, no doubt, these children have unusually sensitive stomachs, and good wholesome food sometimes makes a disturbance in them that would have no effect in those of more healthy parentage.

These cases are of the nature of paroxysmal neuroses, and they are the asthma of babyhood, and they are not to be treated, any more than asthma is, by shielding the sensitive periphery from all stimuli, because now and then such and such things seem to excite an attack—assuming that the healthy infant is exposed only to normal influences. Asthma was never cured by coddling, nor are these attacks. They may be much relieved by a wholesome routine, and by remedies directed to reducing the irritability of the nervous centers.

In addition to the connection between rheumatism and gout, in childhood, it is possible that the so-called essential paralysis of childhood also bears some relation to rheumatism.

Mitral stenosis is said to be congenital and acquired; but a specimen of mitral stenosis in an infant has not been seen; mitral stenosis does not occur in babies. The origin of mitral stenosis is to be sought in the mitral incompetence that is the common, the only form of mitral disease in early infant life. Mitral stenosis does not occur as a malformation, and it cannot occur as the result of inflammatory processes, for the few months of intra-uterine life are not long enough to allow of its production under those conditions of the circulation in the teeth of which it is produced.

Those who devote themselves to the study of the diseases of children will make themselves most useful to mankind, and make their study more interesting and instructive to themselves if they come to their work not as specialists, who are men of single eye, but as those who are accustomed to look all round a case before going special; for, if we except the particular cunning of the hand in the manipulative treatment and management of disease, there is no organ with which, at any rate, physicians are concerned that is not constitutional. There is no part, for instance, more constitutional than the eye, none more so than the nose, none more so than the larynx, none more so than the big toe. It is not enough to know that there is a bacillus tuberculosis, and that its presence works certain destructive processes in our tissues. We want also to know why it affects some people, some families, and not others; and it is conceivable at any rate that the cure or prevention of the ill-effects may, after all, come by understanding or unravelling the meaning of individual proclivity, and not by destroying or starving the invading germ; and this is never more true or more obvious than in children. In the diseases of children there is nothing that gives the smallest countenance to specialism—they are rather to be considered as the grammar of disease.

Third Day—July 30th.

John Chiene, M.D., F.R.C.S. Edin., F.R.S., delivered

the address in surgery.

For his subject he took John Hilton, and for his principle, *rest as a therapeutic agent in the cure of surgical ailments.*

Rest has been divided into mechanical and physiological, but this division is a purely arbitrary one. It has, however, a mental and a bodily aspect—a psychical and a physical side.

We all know it is not work but worry—mental unrest—which kills; a person will bear much physical discomfort in order that he may be relieved of the mental discomfort of his condition. In recommending any special treatment one should take into consideration the effect that the decision will have on the mind of the patient. We all know how frequently operations for carcinoma are unsatisfactory, but we hardly estimate the great mental depression that often follows refusal to attempt to give relief, more especially after the recurrence of the disease—after the primary operation has taken place. An attempt—even if unsuccessful—to remove a tumor will often give the patient a feeling of mental rest in the very thought that no stone has been left unturned in the endeavor to give relief. There is a class of cases that may be termed the "phobias"—syphilophobia, cancerophobia—in which the whole disease is psychic; in no condition is there more pleasure in giving relief, because the condition is a most unhappy one. There is one aspect of the mental side of disease which has not received the attention it deserves. When a patient is confined to bed, away from work, he often suffers as much from the worry of mental inactivity as from the physical disease for which he is under treatment. The prescription "don't worry" might with advantage be burnt; "do some work" should take its place.

This is an age of diagnostic incisions on the part of surgeons, and faith on the part of patients, that after the incision has been made, and the part thoroughly ex-

amined, the surgeon will have more light, and be best able to judge as to what should be done.

In diagnostic incisions we have a valuable aid in avoiding psychical unrest. These diagnostic incisions are the direct outcome of the minimized danger of such incisions. A new diagnostic power has been placed in our hands. The first step in the operation is the diagnosis, and the surgeon has no hesitation in taking this step. He requires from his patient a free hand; he takes less on faith and more on sight.

Dr. Chiene held that chloroform is the best anesthetic. Cocaine as a local anesthetic is of great value in adults. Care must be taken to use a pure solution, and to see that the injection is not made directly into a vein. The use of local anesthetics, such as cocaine, ether, or chloride of ethyl, may be overdone. The work of the surgeon may require to be done in too hurried a manner, not altogether satisfactory either to the patient or to the surgeon. Mental unrest, arising from a feeling of work imperfectly done, worries the surgeon; and in any operation requiring time chloroform is to be preferred to the local anesthetic.

Pain given to a patient, whether in the dressing of a wound or in the examination necessary to make a diagnosis, is a most fruitful source of unrest. Confidence is lost between patient and surgeon; this is more especially true in children. Healthy wounds are not painful; the healing of a wound is a physiological process closely allied to—in fact, it is—growth. Inflammation in wounds can be avoided, and, if avoided, then pain as a cause of unrest is unknown.

One of the most frequent causes of local unrest in wounds and the free serous oozing that accompanies it is the use of unnecessarily strong antiseptics. The use of weaker solutions is gradually replacing the use of the stronger. Asepticism is taking the place of antisepticism. The main danger of contamination is from what is introduced into a wound.

Another aspect of Hiltonism is the use of absorbable drains, so that dressing of the wound is not required in order to remove the drain. Pressure and careful apposition of the edges and surfaces, combined with the absence of any irritating antiseptics, have, to a great extent, done away with drainage of any sort. The safer plan is to provide drainage for twenty-four hours, during the time when reactionary hemorrhage is likely to happen. If India-rubber tubing is used it can be arranged so that it can be removed without disturbance or exposure of the wound. Free evaporation through the dressing is all-important. In psoas abscess free drainage, and its accompaniment, rest, is best attained by a posterior opening at the lowest point of the abscess cavity (the patient recumbent), in the angle between the outer edge of the erector spinæ and the crest of the ilium. So also in retro-pharyngeal abscess; an opening posteriorly to the sterno-mastoid muscle acts in the same way. In both of these forms of abscess the aseptic management of the case is more easily carried out than when the opening is anterior.

Leaden splints should be used to steady limbs after amputation and excision. The splint should be so shaped that it can be unfolded without moving the limb. After excision of the mamma the arm should be anchored by the side with a leaden splint. Pressure should be applied firmly; the distal portion of the limb should be left exposed, so that, if it swells the bandage must be loosened. Pressure is properly applied to any part if it fulfils two conditions, painlessness and non-interference with the blood-current through the part.

Horsehair stitches are valuable, combining rigidity and elasticity—rigidity acting as a splint steadying the edges, elasticity enabling them when cut to be removed without pain. When the stitches are cut, the knot should be grasped and traction made toward the side on which the loop has been cut.

A plaster applied over a boil in its early stages acts as a splint, steadies the part and relieves the pain. The boil is frequently aborted by this simple means.

The value of extension in the treatment of fractures of the lower extremity is universally acknowledged; we have only to take care that it is not overdone. In fractures, injuries, and diseases of the spine, in sacro-iliac disease, and in fractures of the pelvis, the use of double extension is also of undoubted value. Treves has demonstrated the value of rest in enlargement of the lymphatic glands in the neck.

In all cases in which complete rest of the trunk is called for, use a thick and firm mattress made in three pieces, the central portion of which can be withdrawn for the performance of the acts of defecation in both sexes, and the act of urination in the female. In the diagnosis of injuries in the region of the hip, observe the parallelism or want of parallelism between two tapes, one passing through the anterior superior spinous processes and the other through the tips of the great trochanters of the femur.

Dr. Milne Murray has offered an explanation of the action of hot water on the arrest of hemorrhage that well illustrates rest. In epistaxis prevent the air passing through the nasal cavity by tightly grasping the nose, and the epistaxis will frequently cease, the part being kept at rest.

In cranial surgery, we have in the curved incision, as suggested by Mr. Victor Horsley, a means of restoring a flap to cover and give support to the denuded brain-tissue or dura mater. In intracranial hemorrhage, intradural and extradural, we now feel justified in cutting down and arresting the hemorrhage by ligature, or by the hot douche. In apoplexy, an opening into the cranial and dural box is a justifiable surgical procedure, giving rest by relieving tension.

In spasmodic wryneck the patient is in constant unrest. Relief is given by excision of a portion of the spinal accessory nerve.

In rectal surgery gradual dilatation of the sphincter ani before operation gives rest after the operation, as it is followed by a temporary paresis. In colotomy the inguinal region is preferable to the lumbar, because mental worry is avoided by making an artificial anus in a situation which the patient himself has under command. In lumbar colotomy the cul-de-sac between the rectal stricture and the opening in the colon fills with feces and causes unrest. In inguinal colotomy, if the opening is intended to be a permanent one, the whole lumen of the sigmoid flexure should be brought out as a loop through the wound in the wall, and fixed there with long pins passed through the abdominal wall and mesocolon, and again through the abdominal wall, bringing the parietal peritoneum in contact with the visceral peritoneum. Stitches are a source of unrest;

simple apposition is all that is necessary to obtain firm union.

In the ligature of internal piles, the division of the mucous membrane at the anus with scissors before transfixion and ligature, and tying the ligature tightly, so as to completely strangulate the pile, are both means that diminish pain after the operation. The pile-mass dies without any inflammation; it dies of dry, painless gangrene. In cases in which the whole circumference of the gut is affected, excision is the most thorough and satisfactory mode of treatment.

There is no organ in which the value of rest is better illustrated than in the bladder. In disease its systole and diastole can be checked in different ways, and the cystitis caused by the unrest, as evidenced by frequency of micturition, is relieved. This can be done by fixing a gum elastic catheter in the bladder, taking care that the eye of the instrument is just within the cavity, and attaching to the catheter an India-rubber tube that passes into a vessel at the side of the bed. If the tube passes under water below the level of the bladder, and the instrument and tube are full of fluid, there will be, by the siphon-action of the arrangement, a head of water which, by its suction, will remove the water from the bladder as it passes from the ureters. A foot of fall is generally sufficient to keep the bladder empty. If the fall is greater, then the mucous membrane is apt to be sucked into the eye of the instrument, and a block takes place, the bladder filling with urine. When this happens pain will at once be felt by the patient; in fact, his sensations are the best guide to the height at which the vessel at the side of the bed should be placed. By this simple means we can give the bladder rest. In external division of stricture of the urethra the same means can be used to keep the wound absolutely dry and facilitate healing. We can also rest the bladder by perineal or by suprapubic cystotomy. In either case the bladder collapses and the viscus gets rest. In intractable cases of cystitis in the female the suprapubic operation deserves further trial. The unrest after lithotrity is due to fragments of stone left in the bladder after crushing; it is important to crush and entirely remove all the fragments at one operation.

In hemorrhage from the bladder or prostate a suprapubic opening arrests the hemorrhage, the cause of which is the contraction of the bladder, which at once ceases when the bladder is opened. The hemorrhage during the operation may be checked by the use of the hot douche.

In vesical hemorrhage, the mere washing out of the bladder with hot boracic lotion often checks the bleeding; in fact, hemorrhage from any cavity is most easily and satisfactorily checked by the hot douche.

In tracheotomy, Hilton points out the value of rest to the inflamed larynx. One of the main objects of the surgeon is to prevent blood getting into the trachea, and to the lungs, where it is the most fertile source of unrest, setting up pneumonia, the common cause of death after tracheotomy, when death is not due to the disease for which the operation was performed.

In the treatment of cut throat, if we perform tracheotomy at once, and accurately unite the wounded surfaces, we attain more rapid healing, because the wound is not used as a funnel through which the air is admitted to the lungs. Movement of the parts is reduced to a minimum, the part in fact is kept in a state of rest encouraging and facilitating healing.

In the application of a bandage to varicose veins, let us see that it is applied before the patient gets out of bed, and taken off after he is in bed; so also in the application of a truss in hernia the same rule must be constantly followed. Allow the veins to fill, or the hernia to come down once in twelve hours, and the bandage or truss ceases to act as a curative, and only acts as a palliative agent. We allow, by the vein filling or the hernia coming down, a temporary unrest which does away with the good of the previous twelve hours' support of the retentive apparatus. It is well to note that continuous gentle elastic pressure will often act most efficiently, painlessly, and restfully in reducing an irreducible hernia, a prolapse of the rectum or a paraphimosis.

There is another side to this picture, or perhaps it may be the same picture looked at from a different standpoint. Much harm may be done by excessive attention to rest. Evil may result from too prolonged rest. Mechanical rest may, in one sense, be antagonistic to physiological rest. Mechanical rest, in many cases, must be interfered with in order to attain physiological rest. It is here that massage is so valuable.

In breaking down adhesions in old standing cases of fracture, sprain, or strain, one must act in a decided manner. Their presence is associated with limited movement, pain on movement, or pain on pressure, and the use of firmly applied rotatory massage, or the sudden stretching of the tissues that are matted together, often gives immediate and lasting relief.

In the case of nerve-stretching in sciatica, the cases that are benefited are, in my opinion, those that may be called trade sciaticas, due to some special position adopted in the special trade pressing on and irritating the sciatic nerve. The pain is relieved by breaking down the fibrous adhesions in the nerve-sheath and also among the nerve-fibrils. The operation is sometimes a source of physical unrest to the operating surgeon if he does not easily find the nerve; this unrest is avoided if, in operating, the patient lying on his face, the surgeon will stand on the opposite side of the limb to be operated upon. If he then makes an incision over the nerve at the lower border of the gluteus maximus large enough to enable him to introduce his forefinger, with which, using it as a hook, he draws the middle line of the patient, he will at once find the nerve lying externally to the muscles arising from the tuber ischii.

Fourth Day—July 31st.

Edward Seaton, M.D., F.R.C.P., delivered the "Address in Public Medicine." He devoted himself to a consideration of "The Evolution of Local Sanitary Administration."

NEWS ITEMS.

Conviction of a Medical Practitioner for Malpractice.—On Saturday, July 4th, Caleb Charles Whitefoord, M.R.C.S. Eng. and L.S.A.London, was convicted at the Central Criminal Court, London, on a charge of procuring abortion, and sentenced to five years' penal servitude. The evidence made it abundantly clear that his conviction was just.

—*Fortschritte der Medicin*, July 15, 1891.

A Five Years' Medical Course.—The Medical Council of the College of Physicians and Surgeons of Ontario recently passed the following resolution: "On and after July 1, 1892, every student must spend a period of five years in actual professional studies, except as hereinafter provided, and the prescribed period of studies shall include four winter sessions of six months each and one summer session of ten weeks; the fifth year shall be devoted to clinical work, six months of which may be spent with a registered practitioner in Ontario and six months at one or more public hospitals, dispensaries or laboratories—Canadian, British or foreign—attended after being registered as a medical student in the register of the College of Physicians and Surgeons of Ontario; but any change in the curriculum of studies fixed by the Council shall not come into effect until one year after such change is made."

Medico-Chirurgical College.—The following changes have been made in the faculty: Dr. G. E. Stubbs, Emeritus Professor of Clinical Surgery; Dr. W. S. Stewart, Emeritus Professor of Obstetrics and Clinical Diseases of Women; Dr. H. E. Goodman, Honorary Professor of Surgery, Clinical Surgery and Orthopedics; Dr. J. H. Anders, Professor of the Principles and Practice of Medicine, Clinical Medicine and Hygiene; Dr. E. E. Montgomery, Professor of Obstetrics and Gynecology; Dr. Ernest Laplace, Professor of Surgery, Pathology and Clinical Surgery; Dr. W. F. Waugh, Professor of Clinical Medicine.

American Dermatological Association.—In addition to the papers announced to be read at the meeting of the American Dermatological Association, the following will be presented:

The Hypodermatic Use of Hydrargyrum Formamidatum in Syphilis, by Dr. R. B. Morison.

Retarded Hereditary Syphilis, by Dr. R. B. Morison.

Epilation: its Range of Usefulness as a Dermatotherapeutic Measure, by Dr. J. Zeisler.

Hygienic Exhibition at Vienna.—An international exhibition of food supply and domestic hygiene will be held at Vienna from September 1 to December 1, 1891. The organizing committee includes the names of Professors Ludwig, Vogel, Max Gruber, F. von Gruber, Kratschmer and Rösler, besides Drs. Hamelkoos, of Amsterdam, Reichardt, of Jena, Monin, of Paris, and Bein, of Berlin.—*British Medical Journal*, July 18, 1891.

Women Physicians.—Madame Cocepcion Aleixandre has been appointed physician in the "Hospital de la Princessa." It is stated that she is the first woman in Spain to occupy an official position. A Mohammedan girl, Razie-Koutlairoft-Hassum, recently passed, with distinction, the medical examinations at Odessa.—*Int. klin. Rundsch.*, 28, 1891.

The Hygiene of Infants.—A prize of one thousand francs ($200) is offered by the French Academy of Medicine for the best essay on the Prophylaxis of Syphilis during Lactation. Theses in competition must be in the hands of the Academy before the 1st of March, 1892.

Hospital for Women in Bosnia.—It is announced that a hospital for female patients will shortly be erected in Bosnia, all the medical officers of which will be women.

Dr. George E. de Schweinitz has been elected to fill a third chair of Diseases of the Eye created by the trustees of the Polyclinic.

Italian Pharmacopœia.—The new Italian Pharmacopœia is now ready. It has been three years in preparation.

Dr. F. Fuhr has been elected professor extraordinary of surgery at the University of Greifswald.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 28 TO AUGUST 3, 1891.

MUNN, CURTIS E., *Surgeon.*—Is granted leave of absence for twenty days, to commence on or about August 5, 1891.

POWELL, JUNIUS L., *Assistant Surgeon.*—Granted leave of absence for two months, on surgeon's certificate of disability, with authority for his admission to the Army and Navy General Hospital, Hot Springs, Ark.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

ORIGINAL ARTICLES.

ON THE NATURE OF INFLAMMATION, AND ESPECIALLY THE PRODUCTIVE INFLAMMATIONS OF CONNECTIVE TISSUE.[1]

BY HERMANN M. BIGGS, M.D.,

LECTURER ON GENERAL PATHOLOGY AND PATHOLOGICAL ANATOMY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE, PATHOLOGIST TO THE NEW YORK CITY HEALTH DEPARTMENT, CHARITY HOSPITAL, THE ITALIAN HOSPITAL, ETC.

SEVERAL years ago I became convinced that the usual conception of inflammation, the nature, interpretation and sequence of the processes and their significance, was not only incomplete and far from satisfactory, but was based upon essentially false views. There is no better evidence of the incompleteness of our knowledge of this subject than the inability to define the process or describe it in any way that will give any idea of its nature, lesions, signs and symptoms, or terminations. It is often defined by attempting to describe the cardinal signs and symptoms, and we soon find that these signs and symptoms are not only not peculiar to or characteristic of inflammation, but are entirely absent in many of the forms of disease that are called inflammatory.

Cornil and Ranvier define inflammation as "a series of phenomena observed in the tissues or organs analogous to those produced artificially in the same parts by the action of a physical or chemical irritant." Nothing could be more unsatisfactory than this definition, as it simply defines the process by likening it to another of the same kind. Delafield and Prudden say of inflammation: "The conditions of our knowledge are not such as to admit of an exact definition of the term inflammation; nor is there an entire agreement concerning the number of morbid changes to which this term may be applied. We have to be contented with describing the conditions which are probably of an inflammatory character." It is unnecessary to quote other definitions of inflammation in support of the foregoing remarks.

For some time there has been a tendency among some pathologists to consider inflammation from an evolutional standpoint and to regard some aspects of it as conservative. It seems to me that inflammation in all its aspects is to be regarded as essentially conservative or reparative.

[1] Read before the N. Y. Clinical Society, April, 1891.

No attempt will be made to consider the subject exhaustively and in this paper I wish only to throw out a few suggestions, especially on one form of inflammation. I would add that these suggestions represent the aspects of the process that I have attempted to present in teaching this subject during the last three or four years, and I have been more and more impressed in practical experience with the essential truth of the conception, and have been greatly encouraged by the readiness with which students grasp it and put it to practical proof and use.

Since I arrived at the conclusion here enunciated in part, there has been a general tendency among many pathologists toward the acceptation of similar views.

My attention was directed to this subject some years ago by Dr. C. Pittfield Mitchell, to whose writings I feel deeply indebted, although his views differ widely from my own, and I shall introduce my remarks by an extract from his work on *Evolution and Dissolution and the Science of Medicine:* "Single living particles or their assemblages as tissues, organs and compound individuals, present us with a conservative system of forces."

I presume no one will question this proposition. Following this thought a little further it may be said that a disturbance in the equilibrium of these forces produced by external agencies constitutes disease. Now, a readjustment of the equilibrium between these forces, constituting a return as nearly as possible to the normal condition, is in many cases brought about by the processes of inflammation. These processes then become conservative, as are the forces from which they are developed.

I would therefore define inflammation as *the conservative reaction of the organism to noxious influences, brought about through changes in some portions of the vascular system and the connective tissues.* It is Nature's method either of repair or of protecting the organism from noxæ and limiting their action. Its clinical and anatomical features vary and depend upon the nature, mode of application, intensity and duration of action of the noxæ. These noxæ are derived directly or indirectly from without the organism.

The cells and tissues of a compound organism physiologically perform certain functions, and the inflammatory processes are but new functions assumed by certain of these cells and tissues, these

new functions being developed as the result of a morbid condition or a disturbed equilibrium. *Inflammation has always to do primarily with the vascular system and connective tissues.* One of the functions of the vascular system is to supply substances for the nutrition of old tissues and the building up of new tissues. Another function, I believe, is the protection of the organism from the effect of noxious influences acting upon it, these noxæ being derived from without. This latter function is accomplished through the various processes of what we call inflammation. *Inflammation then is only the reaction of the vascular system and its associated tissues (connective tissues) to various noxious influences.* This reaction is essentially conservative, and represents in a general way the most complete protection of the organism or its parts possible under the conditions. The phenomena of inflammation in themselves form only the visible manifestations of the reaction. These manifestations vary in their macroscopical and microscopical appearances according, first, to the nature of the noxæ and their influence on the organism; and, second, according to the ratio existing between the resisting power of the organism and the noxæ. As an illustration of the first proposition we may cite changes occurring in an acute suppurative inflammation as compared with those occurring in a tuberculous inflammation. The differences are quite constant, and depend upon the difference in the nature of the noxæ and their influences on the organism. An illustration of the second proposition may be found in different tuberculous inflammations; in one form, for example, the resistance of the organism to the noxæ is great and the formation of fibrous connective tissue predominates in the process, and in another the resistance of the organism is slight and little connective tissue is produced—the process extends rapidly and suppuration occurs.

It will at once be seen that if this conception of the process is a true one, before we can obtain any correct appreciation of inflammation we must entirely revise our views of the nature of the process, and our instinctive interpretation of the term inflammation. We now regard the inflammatory processes as being in themselves the morbid processes and not as being merely the outward manifestations of Nature's methods of protection or repair. It would be far easier to form a true conception of the nature of the process if we could change its name and call it, for example, *conservation* in place of inflammation. Then the name itself would suggest a preservative rather than a destructive process. It may be easily seen how indistinct and ill-defined the conception of the older pathologists was by the kinds of processes utterly different in nature that they classed together as inflammatory.

I do not propose to take up the consideration of all the forms of inflammation, as this would require far too much time. As to the acute forms, I shall in passing only say a word regarding acute suppurative inflammation. Several of the recent writers, and notably Bland Sutton, have called attention to the essentially conservative nature of suppuration, and this may be demonstrated experimentally with much exactness. One phase of this has been brought out by the researches of Metschnikoff on phagocytosis. The evidence regarding the conservative nature of this phase of inflammation is exceedingly strong.

I shall limit further my remarks to one form of inflammation, viz., the productive inflammation of the connective tissues. It is simply impossible from the old standpoint to explain rationally or intelligently the various conditions under which the productive inflammations of connective tissue occur. There is one reason assigned for their production in one organ in one disease and quite a different one for their appearance in another organ in another disease. It is impossible to harmonize the various theories with the facts or with each other, and yet, the anatomical changes are practically the same wherever the process is found. The conditions under which the affection appears in different situations are also nearly the same, and it would seem as if there must be some ground upon which all should meet. How little these processes were associated together in the minds of the earlier workers is clearly shown by the nomenclature. A student of medicine would little think that the small granular kidney of chronic renal disease, the liver in cirrhosis, the lung in fibroid induration, the heart in interstitial myocarditis, the stomach in gastric cirrhosis, and the brain and spinal cord, in the various forms of sclerosis, all exhibit practically the same anatomical changes in structure.

It is a well-known fact that knowledge becomes simplified as it advances, and it is found possible to group large collections of observations under few heads. That there is some principle that will satisfy all the conditions under which there is a new production of connective tissue, it seems to me, cannot be questioned. The problem presented is to find what this principle is. Another consideration has force in this relation, and that is, that there are strong reasons to regard not inflammation alone but every general pathological process as essentially conservative, and to regard the anatomical lesions of disease as representing, as a whole, the best results, so far as the organism is concerned, that Nature can produce under the existing conditions. The structural changes found in disease should therefore not in themselves be considered as representing morbid processes, but as only representing the injury that

the organism has sustained in its contest with noxious influences. They should be considered as in a general way representing the most favorable reaction between the organism and the external forces acting upon it. It seems probable that the reason we have such processes as inflammation reproduced in practically the same form in various organs and tissues in different species of animals, and in man, is because, in the process of evolution, these reactions to certain external forces conserved to the greatest possible extent the organism acted upon, and were preserved and transmitted to the offspring by a process of natural selection.

The conception of the productive inflammation of connective tissue that I put forward represents the process as being always secondary and as essentially conservative or reparative, and it rationally explains a very large proportion of all the conditions under which productive inflammations occur. Those conditions which apparently cannot be explained now in accordance with this conception will, I believe, admit of explanation when we know a little more of the nature of the process.

We will rapidly take up some of the conditions under which there are new formations of connective tissue, and apply to them the test of this conception.

The first condition under which we have a formation of connective tissue is in the repair of losses of tissue substance or of wounds. When the tissue lost is considerable in amount, unless it is one of the connective tissues, the organism does not reproduce it in kind—or, in other words, when any considerable amount of parenchyma is destroyed it is not reproduced, but its place is taken by fibrous connective tissue. The formation of this tissue is essentially the same under all conditions. There is, of course, no question about the conservative nature of the formation of scar-tissue in the repair of wounds, and it evidently conforms to the definition, "the conservative reaction of the organism to noxæ."

When a foreign body of any kind is introduced into the organism, or when some portion of tissue loses its vitality and so comes to act as a foreign body, there occurs around it a so-called reactive inflammation, associated with the formation of connective tissue. If the foreign body is composed of inorganic matter, as, for example, a bullet, it simply becomes encapsulated, shut off from the rest of the organism and thus rendered harmless. If, on the other hand, the foreign body is organic matter, as a portion of dead tissue for example, not only does it become encapsulated, but it undergoes completely, or in part, what is improperly called organization, *i. e.*, a replacement by fibrous tissue. Capillary loops are pushed into the mass from the vessels in the surrounding newly formed connective tissue. These carry with them round embryonic cells and extend deeper and deeper into the mass. Gradually the mass becomes completely vascularized and as this process goes on the mass is disintegrated and the products of disintegration are carried off. The embryonic cells undergo the usual developmental changes and a scar-tissue is finally formed. Then, depending upon the completness of the process, we find at the point either a simple cicatrix or a cicatrix with the encapsulated and partially disintegrated remains of the original mass. The process that occurs in and around an infarction, a blood-clot situated in the tissues, or a thrombus, is essentially this process. The formation of cysts in the brain after cerebral hemorrhages is, of course, of the same nature—the occurrence of a cyst in the place of a cicatrix being due to the air-tight space in which the brain is situated. The process in each of these cases is evidently conservative; it is Nature's method of separating the dead tissues from the living and of removing the remains of the dead tissues.

The organization of fibrinous exudations is another illustration of the same process—when, for example, on the opposed surfaces of the pleura a fibrinous exudation is deposited; if these surfaces are in contact they are at first agglutinated together; then, as the exudation is dead tissue and acts as a foreign body, there is set up the same kind of a process as occurs around other organic foreign bodies, and it results in the vascularization, disintegration and absorption of the exudation and the formation of adhesions between the surfaces of the serous membranes. The formation of connective tissue here is evidently in response to the same conservative tendencies as in the previous instances.

In the interstitial inflammation in the various viscera the formation of connective tissue is not *primary* but always *secondary*, and is produced in accordance with the same conservative or reparative tendencies that we have seen exhibited in the production of connective tissue under other conditions. The primary change in these processes is in the parenchyma of the organ and is degenerative in character. Nature endeavors to replace the tissue destroyed, but under most conditions does not reproduce the parenchymatous cells, and, in the effort at repair, produces in their place connective tissue. As bearing upon the sequences of the processes in this connection, I may quote from *Evolution and Dissolution*, etc., by C. Pittfield Mitchell, a corollary of Spencer's views of evolution and dissolution:

"Incident forces being equally distributed among the elements of an organic system, the dissolution of functions and structures follows the opposite order of their evolution; the higher and accessory

are less stable than the lower and fundamental; in other words, the more widely cells are separated from the simple fundamental types the more unstable they are. As cells become more highly differentiated and specialized, by just so much do they become susceptible to all forms of noxious influences, or the resistance is inversely proportional to the degree of their specialization and differentiation. This is a principle that needs no elaboration."

Thus we find from an embryological and evolutional standpoint ample confirmation of this conception as to the sequence of the processes. We will now follow it out more in detail in some of the different organs. There can be no doubt that most, if not all, chronic interstitial inflammations are hematogenous in character; they are produced by some noxious influence reaching the organs through the blood. It is thus perfectly illogical to assume that the stable and fundamental connective tissue of an organ first reacts to the depressant, while the highly functionated and differentiated cells of the parenchyma are unaffected. The connective tissues are fundamental, are least differentiated and specialized, and they form the supporting structures of the body.

The connective tissues that are affected in the chronic interstitial inflammations are practically the same throughout the body, and under most conditions certainly are acted upon alike by any noxious influence that reaches them through the blood-current. On the other hand, the parenchymatous tissues are specialized and thus more unstable and less resistant, and they are also subjected in different degree to any noxious influence depending upon the nature of their own function. The kidneys, for example, would be exposed to injury in a much greater degree than would be the case with the liver if there was an excess of the normal urinary excretions in the urine or the presence of some abnormal constituent that is excreted by the kidneys, for the cells of the kidney would then be tried in the performance of their function.

The connective tissue of the liver and kidney, however, might primarily be exposed in nearly or quite the same degree. If we consider for a moment the explanation of the occurrence of cirrhosis hepatis as resulting from alcohol, we see this again well shown. The alcohol passing into the stomach is taken up by the gastric derivatives of the portal vein. It passes with the portal blood to the liver, and coming in contact with the connective tissue of the liver gives rise to proliferation. This is the usually accepted explanation. Let us see how rational it is. There are in the liver, as in other parenchymatous organs, the two forms of tissue—the simple, fundamental and stable connective tissue, and the very highly differentiated and specialized liver-cells. These two kinds of tissue are susceptible to noxious influences in a degree proportionate to their specialization. Yet we are asked to believe that the liver-cells are affected for the most part secondarily, notwithstanding the fact, first, that it is largely a part of their function to dispose of the alcohol, and second, that they are very highly specialized; further, we must believe that the stable connective tissue of the organ has less resistance to the noxious influences than have the liver-cells; and hence, proliferation of the interstitial tissue occurs in response to the irritation. This we are asked to believe, notwithstanding the fact that the connective tissue is for the most part supplied with blood from the hepatic artery, which contains no more alcohol than blood in any other vessel of the body, and notwithstanding the fact that the portal blood containing the injurious alcohol is distributed directly to the liver-lobule and not to the connective tissue. It seems to me that reason and logic have not come into play in this explanation. The new growth of connective tissue here is to be explained in accordance with the theory already enunciated, viz., that the alcohol causes a degeneration of the liver-cells in the periphery of the lobules diffusely throughout the organ, and as the organism does not reproduce them in the attempt at repair, a new connective tissue is produced. It appears to me that there can be no question about the sequence of the processes, although I am aware that some pathologists have regarded it as impossible on anatomical grounds to explain the lesions in this way. The conservative function of the newly formed connective tissue, I admit, cannot now be explained, either in the liver or in some of the other parenchymatous organs, but I doubt very much whether it is as injurious as it is believed to be, and it is formed in accordance with a general method of repair. Nature does not deal with special cases, but with general principles.

We take another illustration. If a considerable portion of muscular tissue is destroyed subcutaneously and aseptically, the muscle is only in part, if at all, reproduced, and its place is taken by newly formed connective tissue. Now, if in place of this a few fibers of the heart-muscle at numerous points in the walls atrophy, degenerate and disappear, as the result of a partial or complete obliteration of some of the smaller branches of the coronary arteries, these muscular fibers are not reproduced, but their place is taken by newly formed connective tissues, and this process of new formation constitutes diffuse interstitial myocarditis. In a large proportion of instances of interstitial myocarditis, the first change is in the coronary arteries. Disease of these leads to obstruction of their lumen, and ischemia of the part supplied; the ischemia results in degeneration. Now, if this degenerative

process went on to any extent, without an associated reparative process, the muscular walls would be destroyed to such an extent that rupture would inevitably occur. But Nature endeavors to repair the injury, and produces fibrous tissue in place of the destroyed muscle, and thus for a long period, and perhaps until the natural end of life, protects the organism from the results that would otherwise have followed—degeneration of the parenchyma. In this instance there can be no question about the sequence of events: the change in the parenchyma is first, and there can be no doubt about the reparative and conservative nature of the process, as it makes possible the continuance of function.

In interstitial nephritis the same sequence of changes occurs. The changes in the kidney are due to the presence of some noxæ in the blood. These noxæ may be the products of over-eating and drinking or of some other poisons that in their excretion act upon the epithelium of the convoluted tubes; and produce a degeneration of them. Following this change there is a secondary new-formation of connective tissues reparative in nature. Most pathologists now admit that in renal cirrhosis the process begins in the secreting portion of the organ, the tubules of the cortex, and that the connective-tissue formation is secondary.

In interstitial pneumonitis or fibroid induration of the lungs, the same explanation holds good. Interstitial pneumonitis, when not associated with tuberculosis, is the result of the inhalation of large numbers of minute particles, such as coal-dust, etc. As we have seen, whenever foreign bodies are introduced into the tissues the organism attempts to render them innoxious either by absorption or encapsulation. In accordance with this tendency there results from the presence of very large numbers of minute foreign particles a diffuse interstitial new-formation.

In the vascular system again, the conservative secondary new-formation of connective tissue is well shown. When there is disease of the arteries producing a degeneration of the middle coats, a new-formation of connective tissue takes the place of the destroyed parenchymatous elements in the muscle and the elastic fibers, as is the case in the heart. In the arteries too, as in the heart, in many cases the cause of the primary degeneration is a disease of the vessels—in this case of the vasa vasorum. The conservative nature of this formation is manifest. When the middle coat is destroyed and the formation does not occur, dilatation and aneurismal formations frequently follow. Another characteristic example of this conservative new-formation occurs in the production of connective tissue in aneurismal sacs. It is not uncommon to find in large aneurisms that the whole of the sac-wall is composed of newly formed connective tissue.

The fibrous new-formations occurring around the infectious new-growths are striking examples of this process. We have learned that in a large proportion of cases of tuberculosis the disease becomes self-limited and restricted to narrow boundaries. This is brought about by the new-formation of connective tissue around individual tubercles or tuberculous masses. The amount of formation of this depends apparently upon the individual resistance to the tuberculous poison. When it is great the tubercle or tuberculous inflammatory products (formed in accordance with the same principle), including the tubercle bacilli, are surrounded by a new fibrous connective-tissue formation, and are thus shut off from the rest of the organism. The frequent localization of tuberculous processes is always the result of such a formation.

I shall refer, finally, very briefly to the sclerosis that occurs in the systemic diseases of the spinal cord. That the new connective-tissue formation in these instances is secondary is now, I think, generally admitted. It is quite impossible to explain the occurrence of a posterior sclerosis, for example, on any other ground than that of a primary degeneration in tracts of nerve fibers which have a certain function. There could be no possible explanation for the occurrence of a new-growth of connective tissue confined to a narrow tract running longitudinally through the cord, when the connective tissue in all parts of the cord is essentially the same. Here, as in the other cases cited, the degeneration is first and the connective-tissue new-formation is secondary, and represents the organism's effort at repair.

With this very imperfect presentation of my conception of the nature of inflammation, and especially the productive inflammations, I will conclude with only a repetition of the view already enunciated, viz., that inflammation pertains alone to the vascular system or the connective tissues, and in all its forms is essentially a conservative process, representing the reaction of the organism to noxæ. It is Nature's method of repair or of destroying or of rendering inert noxious influences. The productive inflammations of connective tissue elucidate in a most characteristic way the truth of this conception, and are to be regarded as being always secondary and as reparative or conservative. The so-called interstitial inflammations should, then, be considered as primarily and essentially degenerations.

Dr. Felix Skutsch, docent in gynecology, has been elected Professor extraordinary at the University of Jena.

RECENT ADVANCES IN THE TREATMENT OF SYPHILIS.

BY CHARLES SZADEK, M.D.,
OF KIEFF, RUSSIA.

IN a lengthy review of the present aspect of the treatment of syphilis, Prof. Kaposi,[1] of Vienna, states that the primary sore, whether hard or soft, is best treated with mercurial plaster. He does not favor excision. Anti-syphilitic treatment should only be instituted when the roseola appears; immediate treatment only delays the constitutional symptoms and has frequently been found to be followed by cerebral symptoms. Kaposi regards inunction as an unscientific, but most efficacious, method of treatment. He recommends subcutaneous injections of soluble preparations of mercury as more scientific and exact. He is decidedly opposed to the hypodermatic introduction of insoluble compounds of mercury, chiefly because they are but slowly absorbed; and if symptoms of mercurialism appear, the mercury stored in the tissues cannot be at once removed in order to arrest the stomatitis or other complications. Iodine and sulphur baths are recommended as protective against relapses after primary relief of the symptoms; hydropathic measures generally are valuable in after-treatment. On the whole, syphilis is characterized as being "eminently curable," though individual predisposition to tuberculosis and other diseases naturally affects the prognosis.

In a valuable paper, read before the neurological section of the Tenth International Medical Congress, at Berlin, Julius Althaus,[2] of London, laid down the following rules in the treatment of syphilis of the nervous system. He considered the prophylactic treatment of nerve-syphilis highly important, as the maladies of this group are among the gravest with which we have in practice to contend, they having no tendency to spontaneous improvement or cure, but a strong tendency to deterioration and death; and, even if judiciously treated, being extremely liable to sudden and severe relapses. He divided prophylactic treatment under two heads, and recommended the excision of the primary sore whenever practicable, in order to destroy the virus in its incipiency or at least to greatly attenuate it, and a mercurial treatment for about three months after the appearance of secondary symptoms. According to his experience, mercury, given efficiently at this stage, acts as a true germicide, leaving the patient's constitution uninjured, as if he had never had the disease. If no such treatment has been followed, there is in any case the possibility, and when there exists a neurotic tendency even a great probability, of the nervous system eventually becoming affected, more especially when such exciting causes as anxiety, grief and excitement, fatigue and privations, exposure to wet and cold, injuries to the head, alcoholic and sexual excesses, and hard intellectual work come into play. Althaus found that a neurotic tendency existed in more than half of his cases, and recommends, after the mercurial course is finished, bracing up by every means in one's power the nervous system in patients that have had syphilis, so as to enable them to resist the inroads of the disease on that system. For the curative treatment of nerve-syphilis he considers the periodical and long-continued hypodermatic injection of small doses of a non-irritant, insoluble preparation of mercury the most important remedy. He passed in review the several modes of employing the metal which have hitherto been in use, and recommends what he terms "carbolized mercurial cream," a preparation that consists of metallic mercury rubbed up with lanolin and afterward mixed with a certain proportion of carbolized oil. He claims for this preparation the following advantages: perfect homogeneity of the mass; great stability; painlessness of injection; absence of swelling and abscesses; great efficiency in truly specific lesions; and absence of the risk of stomatitis and dysentery, if a certain dose be not exceeded. Dr. Althaus discussed the therapeutic value of iodide of potassium, general tonics, the constant galvanic current, and the application of cold and other agents in the treatment of nerve-syphilis. He considers the galvanic current a most important remedy for ordinary secondary lesions and for relieving certain distressing symptoms. He concluded his paper with the hope that the prognosis of these affections in general will eventually become more favorable as the principle of treatment is better understood and more energetically carried out at the beginning.

In selecting a mercurial preparation, in the internal treatment of syphilis, the choice naturally should fall upon such a one as acts with sufficient energy to cause a prompt involution of the manifestations, without unduly irritating the gastro-intestinal tract or affecting the economy in general.[1] Petrini believes that tannate of mercury answers these requirements in a high degree. He employed this preparation in a series of 200 cases of syphilis, and obtained very favorable results. It seemed possible to give it for any length of time without disturbance of the general health. Petrini has found that the drug is mainly eliminated in the saliva, and only to a small extent in the urine. In cases in which three grains were given daily for a protracted period, and in

[1] Wiener medizinische Presse, 1890, 23, 24, 25, 26, 27, 28, 29; Provincial Medical Journal, 1890, 108.

[2] Julius Althaus: Treatment of Syphilis of the Nervous System. London, 1890, p. 35.

[1] Wiener medizinische Presse, 1890, 1, pp. 14–16.

which the urine contained 0.00034 per cent. of mercury, not the slightest affection of the mouth was observed. A pill, containing two-thirds of a grain of tannate of mercury made up with extract of gentian, is ordered once a day with a meal; after ten days or a fortnight the dose is doubled. The patient is treated in this way for twenty-five or thirty days, until the symptoms of the disease have passed off.

Büchler[1] recommends the internal administration of the salicylate of mercury in the treatment of syphilis; having used this drug in thirty-two cases, all of which presented the earlier phases of the disease, he is well satisfied with the results obtained. The ordinary dose prescribed was one-third of a grain, in pill or tablet form, three times a day; this caused not only a rapid involution of the cutaneous manifestations, but also in a like degree that of those of the mucous membranes. Only in three cases was the course of treatment attended by symptoms of mercurialism (in the first case a slight stomatitis was observed after twenty pills had been taken, and in two cases diarrhea supervened after thirty-six and fifty pills, respectively, had been taken). According to Büchler, salicylate of mercury bears the closest analogy to the protiodide of mercury, over which, however, it apparently possesses the advantage of being better tolerated by the gastro-intestinal tract; on enlargement of the spleen the salicylate exerted a most favorable action; on the other hand, it appears to be slower than the protiodide in reducing enlargements of the lymphatic glands. In five cases in which, with the onset of secondary symptoms, percussion showed an increased area of splenic dulness, a perceptible diminution in size was noted after a course of treatment with salicylate of mercury was instituted.

Personally I have used the salicylate of mercury in a series of cases of secondary syphilis, and with most favorable results. I gave it internally in the form of pills, and it was well borne and did not interfere with digestion; in some cases the treatment was continued for six or eight weeks without producing colic or other disagreeable symptoms. The daily amount of the salicylate of mercury that I have prescribed internally for adults has usually varied from one-half to two grains; this was frequently continued two or three months without increase or interruption, or any evidence of tolerance. The ordinary dose of from one-fourth to one-half grain is repeated two or three times daily. The therapeutic effect in all cases was perfectly satisfactory. The eruption began to fade in the course of from eight to twelve days, and the cure was completed in, on an average, from thirty to forty days.

In France a new method of treatment of syphilis has been recommended by Quinquaud:[1] 1000 grams (32 ounces) of calomel are rubbed up with 300 grams (9⅓ ounces) of castor-oil, and mixed with 3000 grams (96 ounces) of diachylon plaster. This mass is spread upon linen so as to yield 14 strips each 3 meters (9 feet) long by 0.20 (7¾ inches) wide; a square of 2½ inches contains about 18 grains of calomel. The skin having been washed with soap, the plaster is applied in the region of the spleen every eight or ten days. Mercury can be detected in the urine on about the fourth day of the application. The method is clean and efficient. Quinquaud has seen papulo-tubercular syphilides resolve in from eight to fifteen days.

The next notable step in advance in the therapeutics of syphilis was in the employment of hypodermatic or intra-muscular injections of mercurial preparations. The subject of the hypodermatic treatment of syphilis with various soluble and insoluble salts of mercury has lately attracted considerable attention among modern syphilographers. The relative advantages and disadvantages of this method of treatment, as well as the employment of new preparations of mercury, has been a theme of liveliest discussion before learned societies; a number of contributions have recently been made upon this subject. The hypodermatic or intra-muscular administration of insoluble preparations of mercury, already a favorite method with some physicians of the old world, has quite lately also received the attention of eminent American specialists.

Moncorvo,[2] of Rio de Janeiro, has employed the hypodermatic administration of the following substances in the treatment of hereditary syphilis: Calomel, yellow oxide of mercury, gray oil, and the salicylate of mercury. The vehicle used for these agents was liquid vaselin. Calomel, the oxide and the salicylate were administered in doses of from 3 to 5 centigrams (½ to ¾ grain); gray oil was used in the proportion of from ½ to 1 cubic centimeter (♏vijss–xv). The last was better tolerated than all the others, the injection being attended and followed by no pain. Moncorvo says that the results did not quite equal his anticipations; that is to say, although beneficial, the hypodermatic injections, although administered at very short intervals (from four to ten days), did not seem to bring about a complete cure as rapidly as one would be inclined to expect. No toxic symptoms, however, were observed. Moncorvo concludes that in a general way

[2] Satellite, February, 1890, pp. 110, 111.

this method is less active than that of friction with unguentum hydrargyri.

Herman Klotz,[1] of New York, in a most interesting and valuable paper, related the results of a series of therapeutic experiments made by him with different insoluble mercurial preparations; calomel, the yellow oxide, and the salicylate of mercury were all tried, but the yellow oxide, in the strength of 1 to 30, suspended in water, olive oil, or vaselin, was mostly used. Two hundred and four intra-muscular injections, distributed in thirty-eight series (which were separated by intervals of several weeks or months), had been given twenty different patients. An average of ten injections was given each patient. The greatest number of injections made on any one patient was twenty-four; the smallest, three. As a rule the treatment was well borne; the pain was usually of but moderate intensity. In two cases abscesses were noted, both following an injection of calomel suspended in water; none followed when calomel was suspended in oil. Occasionally slight induration was noted at the seat of the injection. Salivation was absent in almost all cases; the gums suffered much less than during internal treatment or during a course of inunctions. Only in one case did a severe stomatitis develop. Diarrhea, as a result of the injections, was observed but once; in two cases the symptoms of pulmonary embolism were observed, but without any dangerous consequences.

The therapeutic effects of the treatment were in general very satisfactory: the early muscular and papular syphilides disappeared rapidly after two or three injections, and, as a rule, had left no trace when the last injection of the series was made; the tubercular syphilide was at first most favorably influenced by the yellow oxide, but the effect was not lasting; after early recurrence the iodide proved more useful, though it would not prevent the formation of a gummatous periostitis several months later. The affections of the mucous membrane of the oral cavity and the throat were not less favorably influenced by the treatment than those of the skin; even the deeper ulcerations healed rapidly. But in two instances new ulcerations on the posterior wall of the fauces were seen to develop during the period of injection, so that iodine had to be substituted. In the two cases of tertiary syphilis the effect of calomel injections was most satisfactory. Klotz says that there is, however, a great difference in the effects of the different salts, calomel undoubtedly taking first rank and exerting a much more powerful action than the yellow oxide and the salicylate of mercury. It seems that the effects depend, to a certain degree, on the quantity of metallic mercury contained in the salt, a larger number of injections being required as the salt contains a smaller percentage of mercury. In accordance with the observations of Jadasohn and Zeising, Klotz found that while seldom more than four injections of calomel were necessary, six to eight of the yellow oxide and of the salicylate were required to obtain the same results. Klotz concludes that the treatment of syphilis with injections of insoluble mercurial salts is most valuable.

On the continent of Europe the various hypodermatic methods of treating syphilis are at present the order of the day. The number of mercurial salts employed for this purpose continues to multiply, some observers giving preference to the soluble, others to the insoluble, preparations. Those which appear to be receiving most attention just now are hydrargyrum salicylicum, thymolo-aceticum, and benzoicum. The salicylate has recently been reported favorably upon by Gold, Lindeborn, and Lezius.

Gold, of Odessa,[1] claims to have treated 302 cases of syphilis by subcutaneous injections of different insoluble mercurial salts, and to have made 1609 injections without producing a single abscess; infiltrations occurred in four cases. He believes that the salicylate of mercury is altogether the best insoluble preparation of mercury for hypodermatic administration in syphilis.

Lindeborn,[2] of Frankfort-on-the-Main, has employed the salicylate of mercury in the treatment of syphilis in the following solution: Hydrargyri salicylatis, one part; paraffini liquidi, ten parts. The injections were made every five days. The therapeutic results obtained were most satisfactory.

Lezius,[3] of Dorpat, has recently published a paper upon the treatment of syphilis by injections of salicylate of mercury, in which he claims to have obtained favorable results with this preparation. He has employed this remedy in twenty-four cases of secondary and in only one of tertiary syphilis. The formula that he employs consists of one part of the salicylate of mercury and ten parts of liquid vaselin. The injections are usually made every seven days in the gluteal region. Twenty-five patients had received one hundred and twenty-six injections. He found that usually after two or three injections had been made, exanthematous eruptions commenced to disappear, while after the fourth or fifth injection the broad condylomata were well cured. Recent syphilitic manifestations required usually only from three to six injections. In a case of cerebral syphilis

he claims to have obtained a remarkable curative result, the symptoms rapidly disappearing after four injections of the drug. Finally, Lezius claims that the injections have never been followed by any local inflammatory action, no abscess or toxic symptoms, while stomatitis occurred but rarely, and was in no case severe.

Personally, I have employed intra-muscular injections of salicylate of mercury in a long series of cases of secondary and tertiary syphilis, and always with most satisfactory results. The solution used was as follows:

℞.—Hydrarg. salicylatis . . gr. xvj–xxiv.
Mucilag. gummi arabici . gr. viij.
Aquæ destillatæ . . . f℥vss.
M. ft. suspension.

Of this, one Pravaz syringeful (♏xv) was injected at a time; this was repeated at intervals of three days. I selected the gluteal region as the site for injections. The time during which the cases were treated varied from three weeks to two months. The therapeutic value of the salicylate of mercury was especially remarkable in syphilitic affections of the skin and of the mucous membranes; syphilitic eruptions and slight relapsing forms yielded to the treatment in from two to four weeks. The local reaction was slight—even less than after the use of calomel and of the yellow oxide of mercury. In no case did an abscess form, either at the point of injection or in its vicinity. Infiltrations were rare, and the more pronounced symptoms of mercurialism did not develop.

The thymolate of mercury was in 1889 recommended by Jadasohn, Zeising and Welander for hypodermatic medication. Cehak,[1] of Vienna, has used this drug in a series of cases of secondary syphilis, and is satisfied with the results obtained. He injected a five or ten per cent. emulsion of this preparation in liquid paraffin. The injections were usually made every two or four days; each patient received from six to twelve injections without noticing any local irritation. In no case did an abscess form.

The most recent advocate of the thymolate of mercury is Dr. Löwenthal;[2] he has recently published a valuable article on the intra-muscular injection of this drug in the treatment of syphilis. This paper is based upon his experience with its use in sixty patients, to whom two hundred and ninety-three injections were given, with the following results: Twelve of the patients remained under treatment; the others appeared to have derived unquestionable benefit from the treatment. The injections were made once a week for two or three months. Löwenthal used a ten per cent. suspension of the thymolate with glycerin. Improvement in the syphilitic symptoms became apparent after a few injections. No abscesses were produced in the course of the injections. The pain produced by the injections was mitigated by the addition of cocaine. Salivation was observed only in persons with carious teeth or similar complications. In one patient nausea and rigors were produced by the injections. Löwenthal thinks thymolate of mercury worthy of a place among the means of treating syphilis.

I have also with advantage used the thymolo-acetate of mercury in several cases of syphilis The formula of the aqueous suspension to be injected is as follows:

℞.—Hydrarg. thymolo-acet. . 1.5 parts.
Mucilag. gummi arab. . . 0.5 "
Aquæ destillatæ . . . 20 "
M. ft. suspension.

The injections of a seven per cent. suspension of the drug were made at intervals of three or four days. From six to ten injections suffice in most cases of recent and non-inveterate syphilis. I have especially observed the therapeutic value of the treatment in the early stages of the disease. Syphilitic roseola and the papular affections of the mucous membranes yielded after from four to six injections, or in from twelve to twenty days; the relapsing syphilides, after from two to four injections; the papular cutaneous forms and the ulcerative affections of the mucous membranes after from six to eight injections, or in from fourteen to twenty-five days; the pustular and tubercular affections of the skin required a larger number of injections. This method of treatment occasioned little pain; in no case did an abscess or considerable infiltration develop. During the last two years I have not encountered as a result of the toxic action of mercury disturbance of the digestive organs, of respiration (embolism) and circulation, or any general disorder of importance.

The hypodermatic administration of the new soluble mercurial salt—benzoate of mercury—has recently been employed by the following French physicians: Balzer and Thiroloix,[1] and Cochery.[2] Balzer and Thiroloix have in fourteen cases of syphilis (all in women) employed a watery solution of the benzoate of mercury with sodium chloride and a little cocaine (hydrarg. benzoat., 0.3; sodii chloridi, 0.1; cocainæ hydrochloratis, 0.15; aquæ destillatæ, 4); they made into the back daily injections of the contents of a Pravaz syringe (0.01).

[1] Allgemeine Wiener medicinische Zeitung, 1890, 7, 8, 10, 11.
[2] Deutsche medicin. Wochenschrift, 1890, 25. British Journal of Dermatology, October, 1890.

[2] Constant Cochery: Traitement de la Syphilis par les Injections sous-cutanées de Benzoate du Mercure. Thése, Paris, 1890.

From fifteen to forty injections were given, according to the severity of the case. Of the whole series treated in this way, eight were completely cured; four were decidedly improved; in one case the result was unsatisfactory, although thirty-one injections were administered. The local reaction (pain and infiltration) was slight, and an abscess formed in no case.

The succinimide of mercury recommended two years ago by Vollert, of Strassburg, for hypodermatic use, has recently been employed by Selenieff[1] in a series of thirty-three cases. He employed this drug subcutaneously in a one per cent. solution, and found the therapeutic effects not very marked; he recommends the treatment in mild syphilis, especially in women and children.

Hüfler,[2] of Erlangen, warmly recommends in the treatment of syphilis a new mercurial preparation—the hydrochloric gluten-peptone sublimate, which contains about twenty-five per cent. of mercury. He has treated seventy patients with this preparation, in all upward of thirteen hundred injections having been administered. The solution was so diluted that each syringeful contained two-thirds of a grain, corresponding to one-sixth of a grain of corrosive sublimate. Each of the patients received about twenty injections. From the results obtained, the author regards the preparation as prompt and reliable in action. He did not observe any irritation or the formation of an abscess at the point of injection.

Boer,[3] of Berlin, advises the use of the oxycyanide of mercury in syphilis. He employed this drug hypodermatically in thirty cases of syphilis in a one and a quarter per cent. water solution, making a daily injection of the contents of a Pravaz syringe into the gluteal region or in the back. The duration of the treatment varied from nine to forty days.

Hartman[4] has administered the black oxide of mercury in sixty-eight cases of syphilis. The drug was injected in the form of a 10 per cent. emulsion. Syphilitic symptoms disappeared after five or six injections. In ten cases abscesses followed; in three, stomatitis; pain was always very moderate.

Lindstroem,[5] of Kieff, has employed subcutaneous injections of so-called "gray oil" (introduced into the therapy of syphilis by Lang, of Vienna) in fifty-three cases of syphilis. The dose corresponded to 0.15 (2¼ grains!) of metallic mercury for each injection. His opinion is not favorable to the therapeutic value of the remedy; he says that gray oil acts on syphilitic lesions with comparative slowness during the treatment; fresh eruptions may appear; the injections are frequently most painful and give rise to infiltrations; stomatitis occurred in 48 per cent. of cases; embolism was observed in two cases; relapses seemed to be more frequent than in cases treated with other mercurial compounds.

The following inconveniences and dangerous accidents following subcutaneous injection of some of the mercurial preparations have been recently reported. Maudey[1] in one case observed necrosis of both maxillary bones as an effect of protracted injection of gray oil. Runeberg[2] has reported a case of death after injections of calomel; dysentery was observed by Cramer[3] as a consequence of the injection of calomel; Touton[4] relates a case, in which, after three injections of salicylate of mercury, an abortive herpetic eruption appeared in groups of firm papules in the course of the left posterior femoral cutaneous nerve and accompanied with pain in the left gluteal region; Petersen[5] reports a case in which an extensive erythematous and macular eruption followed half an hour after a calomel injection; the eruption faded in the course of a few days. A second injection, a week later, was followed by a similar, but much less severe eruption. A third injection failed to produce the exanthem. In the same patient a series of injections with the yellow oxide was also followed by a similar train of cutaneous symptoms.

Augagner,[6] of Lyon, has related a singular case, illustrating the inconveniences of the hypodermatic administration of the gray oil of Lang. In the case of a syphilitic patient who was treated with injections of gray oil, the disease followed its regular course and the patient was dismissed as cured. He subsequently, however, displayed a liability to the frequent occurrence of ulcerous stomatitis. Some time later he received a blow on the thigh, at the place where the injections were made; he was taken with so severe an attack of stomatitis that he had to go to the hospital for treatment. There he was found by Augagner to have two tumors, from one of which metallic mercury could be drawn by simple puncture and expression; the other tumor had to be removed and was found also to contain mercury.

The conclusion may be formulated that injections of insoluble salts of mercury at the present time con-

stitute one of the most favorite and valuable methods of mercurial treatment in the practice of a number of specialists of the Old World. Comparative experiments with the various remedies recently introduced for the subcutaneous treatment of syphilis have resulted in demonstrating the superiority of the salicylate and the thymolate of mercury, as convenient curative agents.

Of non-mercurial remedies for the treatment of syphilis, a substitute for iodoform, iodol, is one of the most recent additions to syphilo-therapy. This drug was recommended four years ago by Pick, of Prague, who claims good results from its external and internal administration in tertiary syphilis. I have recently published a paper on the external and internal use of iodol in the treatment of syphilis,[1] in which I record the result of the internal administration of iodol in twenty-two cases of syphilis (five cases of secondary and seventeen cases of tertiary syphilitic manifestations). Iodol was given continuously for two or three months, in doses of from eight to sixteen grains (0.5 to 1.0 grams), two or three times a day. The value of iodol consists in its harmlessness, tastelessness and odorlessness, and in the large proportion of iodine it contains; the intestinal tract is not disturbed by its employment. The therapeutic results were most satisfactory, excepting in two cases of inveterate syphilitic hemiplegia. Externally I found iodol most efficacious in several cases of tertiary syphilitic ulcerations. Cerna[2] has also used this drug in many cases of syphilis, with excellent results. He gives iodol in doses of three grains, three times a day, gradually increasing the dose to as high as twenty grains a day, without producing symptoms of iodism.

Another new anti-syphilitic remedy, cascara amarga, has been recently recommended by Haines,[3] for the internal treatment of syphilis. He believes that this remedy is almost specific, especially in the ulcerations of tertiary syphilis, and states that he has treated seven cases of tardy syphilis with very good results. The last case was one of sloughing of the palate and back of the pharynx; the patient had exhausted the orthodox treatment, and Haines recommended the fluid extract of cascara amarga with iodide. The results of the treatment were brilliant. In secondary syphilis he has seen no good follow the exhibition of the remedy. Its field in syphilis appears to be in the treatment of the tertiary manifestations when marked cachexia exists —cases in which mercury could not be given, and in which the depressing effect of the iodides would be dreaded.

SUPRA-VAGINAL EXTRA-PERITONEAL HYSTERECTOMY, INCLUDING THE PORRO OPERATION.[1]

By JOSEPH PRICE, M.D.,
of Philadelphia.

The question of the justifiability of any operation must be determined by the ultimate results of that operation, together with the risks attending it. To these must be added a comparative estimate of the success of the other methods of treatment, with their results, dangers, and mortalities. The subject is far too wide to be considered in a single paper, which, under the conditions imposed, must necessarily be short, and hence one side of the question must be principally treated, and the arguments and facts elicited stand as data to settle many moot points in the general controversy without entering directly thereinto.

The position assumed against hysterectomy to-day by many who consider themselves authorities in the matter, and hence lead the van in the opposition to operative interference by this method, is one principally of misinterpretation of facts or of sentimental pleading. On the one hand they assume that surgeons deal indiscriminately with all fibroid tumors by a resort to the knife; and, on the other, that any surgical interference is mutilation. On this latter term especial emphasis is laid. Now let it be understood at the outset that only a small number of fibroid tumors require absolute removal. Let it be understood further that many of these tumors, though at first troublesome, disappear more or less rapidly, and cease to cause annoyance. Let it be understood again that by the term fibroid I do not include all hypertrophies, engorgements, or enlargements in which the sound is said to enter two and three-fourths inches, subinvolutions, defective involutions, and the like. By fibroid tumors I mean such growths as when seen and handled leave no doubt that they were foreign bodies as much as the splinter under the nail or the necrotic bone under the periosteum; that they have been a source of misery to the patient, and might have continued a source of revenue to the physician; that without exception the women so suffering, from the complexity of their complaints, referred to bladder, bowels, and circulation, as a result of adhesions and of tubal and ovarian disease, were willing and urgent to be relieved, and in many instances hailed operation as affording at least a chance for life that without operation was not worth having. It is further to be considered that in a considerable number of the cases under consideration in this paper, the operation of hysterectomy was not entertained at the outset, but was performed

[1] Read before the Section of Gynecology and Obstetrics of the American Medical Association, Washington, D. C., May 7, 1891.

as a last resort, because other and less radical measures were not feasible. By less radical measures I mean removal of the appendages; and when I say that this operation was not possible, I wish to draw attention to the fact that in saying that no abdominal operation but hysterectomy is difficult, Mr. Keith underestimates and misstates the situation. I have repeatedly performed hysterectomy when removal of the appendages was impossible. So has Mr. Keith, and his statements in regard to this are just as incomprehensible as they are in some other matters relative to his pretended abandonment of the operation of hysterectomy.

As to the second objection, that of mutilation, little need be said. Describing one tumor removed by him, Mr. Keith says: "No line of demarcation could be made out between the peritoneum and the tumor-wall; adhesion was everywhere most intimate." The omentum occupied the interval between the tumor and the wall, being adherent to both; as all the tissues were edematous, this only increased the difficulty. The transverse colon was firmly attached all along the upper margin; in separating this it was deprived of its omentum and of part of its mesentery. The omentum was so lacerated that most of it was cut away. On examining it after removal from the body it was impossible, even by careful dissection, to separate the adherent peritoneum. As to the result, he says: "The wound healed by first intention. Her health continues excellent, though she is a hard drinker." This tumor weighed thirty-five pounds. With the disturbed relations of the pelvic and abdominal viscera, as a result of adhesions, pressure, and edema, with pain and hemorrhage, we are, I suppose, to consider that this woman had not been mutilated by her tumor, and that only the surgeon's knife in removing the tumor instituted the work of mutilation. This argument in its fallacy can only equal the resolve of the opponents of ovariotomy not to mutilate and endanger the lives of women suffering with ovarian tumors. The sufferers might die, but they should not be "mutilated." Cow-horns might pierce the abdomen, and the patient recover, but the surgeon's knife, never!

Another point here to be insisted upon is that the size of the tumor sometimes—nay, often—has comparatively little to do with the urgency of the conditions necessitating operation. Many of my specimens show this unquestionably. A moderately large, symmetrical tumor may cause little trouble, because, in its growth, it has risen uniformly in the pelvis, and its presence is not more irritating than the fetal head. Given, however, a pelvis-bound fibroid, interfering with all the pelvic organs, together with the pelvic circulation, the situation becomes the most urgent possible. The urgency is still further increased if the tumor be not regular, but nodular, containing cysts or excrescences of various degrees of hardness and size. These are the tumors that are anomalous, and the boundaries of which can as little be determined without actual exploration as the jungles of Central Africa. They defy exact definition, and the surgeon can promise nothing as to their removal until they are seen and felt. In such cases the removal of the appendages is often impossible and often more dangerous than the removal of the entire uterus with its appendages.

The question now arises: What can hysterectomy promise and what can it accomplish? The decision arrived at long ago by Mr. Keith, that unless the mortality at that time could be reduced the operation should be abandoned, was correct. When with his prophetic eye he looked into the future and saw that the operation would never assume a position similar to that of ovariotomy, he was wrong. In the first place his ideas were based upon the unfair limitations he forced upon the operation. He says: "No one was operated upon in good health or condition." This is the key to the whole situation. It was not the operation that was so much to be dreaded as was the condition of the patients. If we operate on the death-bed we must have post-mortem results.

The advantage gained by early operation in hysterectomy is no less real than it is in all other abdominal disease requiring surgical interference. After his wonderful experience, as surgeons all know, Mr. Keith decided the operation justifiable if the mortality could be reduced to 5 per cent. in the bad cases. This can and has been done in the series I submit to the Section: 53 supra-vaginal extra-peritoneal hysterectomies, with 3 deaths; 43 consecutive operations without a death.

The combined mortality of all operators, however, is no criterion by which to judge the operation. The results of those operators who have worked out the details of procedure, with a view only of adding to its safety, with no idea of engrafting upon the procedure something that is more dangerous, as it is more cumbersome, must receive due consideration. The waste of time in carrying out some of the details of certain so-called original methods alone condems them. In all abdominal surgery expedition is essential to success, and nowhere is it more so than in the removal of the uterus.

The idea that in order to receive and merit universal acceptance, an operation must follow and conform to a general cosmetic idea is as ridiculous as it is fatal, and has given rise to a score of so-called original ideas that are only curiosities and often freaks. Upon this argument the condemnation of

the clamp or *serre-nœud* is thoroughly justifiable. With the results by all odds in its favor there is no excuse for experimenting with human life by trying to find something ideal to take its place. If these experiments are to be continued, let some other way be found than by experimenting on patients. The truth becomes more and more evident that intra-peritoneal operations can be performed with safety only in the very smallest number of cases, and even in these not without grave danger, owing to the peculiar nature of the stump. This I have elsewhere discussed. It is only necessary here to repeat that the stump is contractile, often cartilaginous and tough and unyielding. Its bloodvessels are rather to be considered sinuses; consequently when an attempt is made to ligate each bleeding point, the number of points at which a ligature must be left is often enormous, and of itself sufficient to cause pathological changes in the stump. The constriction of the stump, then, is, from its nature, the best mode of treating it. The Kœberlé *serre-nœud* affords the best means of applying such constriction. The method of regulating this constriction will be again referred to.

Coming now to the technique of the operation, it is first to be said that it is one of absolute, careful, painstaking watchfulness. Routine is possible only in the simplest conditions, and each additional complication must be treated and overcome as it arises. It is fatal to the success of the operation to go on in the face of difficulty after difficulty, unless each one is cleared up to leave clear ground for that which follows. The incision—median—is to be regulated according to the size or the depth of the tumor. A mass deeply fixed in the pelvis may require a very large working-space. All bleeding vessels are to be controlled as they are encountered. The mass is then to be studied, and its adhesions located as its removal is attempted. These adhesions are to be regarded as stages of the operation, each one being dealt with and overcome before another is approached. One is not to be abandoned and left bleeding while another is sought and freed. Such work will result in confusion, and prolongs the operation if it does not defeat the result. If bowel, omentum, bladder, abdominal wall, transverse colon or other part of the intestine be adherent, each is to be freed and carefully examined before it is abandoned; all damage is to be repaired at once. While such manipulation is being conducted, all viscera necessarily exposed are to be kept warm, and to be frequently douched with hot water. The bladder is to be most carefully looked after. Complications that endanger this organ, the ureters, or the kidneys are those that most frequently result disastrously in all abdominal operations.

Whether or not the bladder should be injected, in order, when all boundaries are lost, to have at least one landmark, is a question not always easily decided. Sometimes the bladder is so crowded in the pelvis that its injection would accomplish very little; in others, there would be a distinct advantage in distending the organ. The best rule, it seems to me, is to act in each case according to the conditions presented, and not to lose sight of the possible benefit that might accrue from distending the viscus. Having freed the adhesions, the mass, if not already raised while the adhesions were being freed, is to be lifted out of the pelvis. This may sometimes be done without other instrument than the hand; at other times, the broad-bladed corkscrew is necessary. In the case of vascular or myomatous tumors, the capsule of the tumor is to be regarded as sacred ground, bearing the admonition, "Keep off." To wound the capsule is to seriously complicate the operation.

Having so far seen that the operation is one involving a knowledge of the most varied intestinal surgery, and that from the nature of the adhesions one must be prepared to perform any or all of the common abdominal operations, we must briefly retrace our steps and consider the removal of the appendages as a distinct part of this operation. In certain cases the operation is begun with the intention of removing only the appendages, but by reason of the diseased condition of these, and the consequent adhesions and relations, the ablation of the entire uterus is alone feasible, and is forced upon the operator as a last resort. In such instances, the extent of adhesions is apt to be greater and their complications much more serious than was anticipated, even with a careful antecedent *reconnoissance* of the situation. It therefore again becomes apparent that in no case of anticipated removal of the appendages for fibroid tumors should the operator undertake the operation unless he is also prepared to perform hysterectomy. Possible successes have in this manner become disastrous failures.

In the final steps of the operation, to wit, in dealing with or in making the stump, the most skilful surgeon will often find himself hard pressed. In some instances the procedure is as easy as the easiest operation in surgery, under established routine; in others, and for these no absolute rule can be laid down, ingenuity is often taxed to the utmost to obtain and to utilize the tissues freed for the formation of a stump. If it is necessary to make a stump, the capsule of the tumor is to be incised, hemorrhage being controlled by an elastic ligature, the broad ligaments freed and retracted, the mass raised, and the peritoneal covering utilized in shutting off the pedicle from the peritoneal cavity. This all seems clear and concise, but to appreciate the method and its difficulties, a clinical and operative study is in-

dispensable. Herein lies the fallacy of determining the mortality of the operation by the results of all operators. The learner's mortality must always be great in the first series of cases, unless the conditions are extremely simple, or unless the work is done in association with a more experienced worker, who himself has wrought out a technique from the knowledge of the work to be accomplished.

In the application of the *serre-nœud* after the stump has been freed, or made, care must be taken that it is not placed so far down against the vaginal vault as to include the ureters, or to exert too much traction on the abdominal walls. Care being taken to include nothing but the stump, the *serre-nœud* is tightened by means of the screw, the pins are placed in position, and the tumor cut away. The *serre-nœud* is then again tightened to stop all oozing. The stump is then carefully trimmed; while the stump is firmly held in the lower angle of the abdominal wound, the parietal peritoneum is stitched to the peritoneum of the stump, and so excludes the *serre-nœud* from all communication with the abdominal cavity, the two peritoneal surfaces being stitched together below it. The remaining abdominal incision is now closed, drainage being provided for or not, according to the number and extent of the adhesions. The stump again receives attention, dry gauze being firmly packed around it and between it and the abdominal wall. After having been drawn by convenient stitches into as small a compass as possible, its cut surface is dressed with a dry powder, iodoform being the one generally used in my work. In Greig Smith's description of the operation, the final treatment of the stump is left without the exact consideration it deserves.

Finally, I would say that in all these operations the results are astonishing in their smoothness. In many cases there is absolutely no bad symptom, and, in the majority, the recovery is a matter of less concern than in many pelvic cases. In only one case have I had the misfortune to implicate the ureter, and in this I have learned a lesson that hereafter shall stand me in good stead. The details of the case, with its ultimate results, will be the subject of a further communication. The cases, once recovered, are permanently well, with no danger of recurrence. A consideration of my cases shows that the mortality has been reduced below that of the supposed more conservative treatment. The wonder to me is that Mr. Keith, after detailing operation after operation, in which a similar success was recorded, can now so far forget his wonderful record and wish that he could undo his work in order to experiment with palliative and tentative measures. Surgery is an art; its progress must depend on the labors of original workers. The man who stops half-way in the midst of crowning success must leave his art where he found it, and, retreating, abandon his position, unprotected.

A REPORT OF FIVE CASES OF CHRONIC MERCURIAL POISONING.

BY LEWIS H. ADLER, JR., M.D.,
INSTRUCTOR IN RECTAL DISEASES, PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE.

THE following cases of mercurial paralysis are interesting examples of the toxic effects of mercury upon persons brought in contact with the metal or with the vapor, and are recorded as a contribution to the literature extant upon the subject of chronic mercurial poisoning.

It will be observed that in these cases the palsy first affected the upper extremities, and then by degrees the entire muscular system. In none of the cases were the muscles of mastication and deglutition involved—this condition occurring only in very advanced cases of the disease. In only one case was there a distinct line, blue in color, upon the margin of the gums. Ankle-clonus was not present in any of the cases. In four instances the knee-jerk was exaggerated. All the cases showed marked mercurial salivation, but in no case was there any history or evidence of the cathartic effect of the drug upon the bowels.

The treatment of these cases consisted in removing the patients from surroundings in which they would be exposed to the ingestion of more of the poison; warm baths were ordered; potassium iodide in gradually increasing doses was prescribed and a mild tonic, such as Basham's mixture, advised. The bowels were also carefully regulated.

CASE I.—P. M., a male, forty-five years old, married, employed in the manufacture of felt hats, presented himself for treatment in November, 1889, with the following history: He had always been a healthy man, and was the father of four robust children. For nine years he had worked in a hat factory, thus coming in more or less frequent contact with mercury, which is used in the business. For a year past he had not felt like himself and for the last six months he had steadily become worse. During this time, his teeth had loosened; his hands had become tremulous and unsteady—so much so, that he could not hold a newspaper still long enough to be able to read it with any satisfaction. Later on, his eyes began to twitch, and in attempting to read, black spots would appear and dance about before them. In walking, his gait was tremulous and unsteady. Upon being questioned, he stated that sexual power was dormant, and had been so for over a year; his weight had markedly decreased — as much as twenty-five pounds during the preceding six months; his appetite had been and still was very poor; the hair had fallen out from his face and head in considerable quantity. He also stated that he

was subject to attacks of vertigo. The bowels were regular and he was not subject to diarrhea. Ptyalism was marked; speech was thick and articulation slow; his memory was poor, and his breath fetid; the border of the gums, at the margin of the teeth, was marked by a distinct *blue line;* the extremities were in a state of constant tremor.

Case II.—John M., fourteen years old, employed in a hat manufactory, came under my observation January 9, 1890. His father stated that the lad was always healthy and full of life until the present illness, since which he had been "dead-like" in his actions. He had been employed in the hat factory for over a year, sweeping the floor and feeding the machines with fur. The history of his illness was, that four months previously he had begun to feel weak; his memory perceptibly failed, and temporary headache ensued; there were marked signs of ptyalism, as well as a bad taste in the mouth and a fetid breath. He was costive; the appetite was unimpaired. About a month later, his gait in walking became unsteady and his feet felt like lumps of lead. In attempting to pick up anything, he was obliged, for want of proper control over his movements, to make several ineffectual attempts. The appearance of the boy betokened a dull intellect. Upon extending the arms, and only then, did marked ataxic symptoms appear in the upper extremities. In walking, the legs dragged and knocked against each other. The tongue was quite tremulous upon protrusion. There was no apparent loss of power as shown by grasp of hand. The teeth were sound and perfect, the gums spongy, bleeding upon slight pressure. The breath was fetid and the salivary secretion profuse. When told to extend the arm with the index finger protruding, and to quickly touch the tip of nose, he obeyed only after an effort and in an uncertain manner, more frequently touching the face, forehead or bridge of nose. Given a pencil and told suddenly to drop it, he had great difficulty in releasing his hold of it. The patellar reflexes were greatly exaggerated, and the ankle clonus absent.

Case III.—M. A. B., thirty-five years old, married; also works in a hat factory. Previous to this employment he had been an hotel-keeper. As a child he was healthy. He had scarlet fever at the age of ten. He never drank to excess, but as a youth indulged freely in venery. At the age of nineteen he contracted syphilis, and was treated for this disease for nearly two years by a well-known genito-urinary surgeon of New York. He was married at the age of twenty-four, and has had five healthy children, his wife never having had a miscarriage. He has been employed in his present business for ten years. He formerly weighed 156 pounds, but since working in the hat factory he has gradually lost flesh from year to year. Soon after entering upon his duties he experienced frequent attacks of indigestion and spells of biliousness, from which affections, he tells me, most of the men in his department suffer. He also states that, whilst some men are affected with diarrhea, he, with the majority of the employés, is constipated. Another curious fact he related was that some of the workmen had no control over the passage of urine; especially was this the case among those employed for any length of time upon the mercurialized materials. The first serious attack of the patient's present trouble dates from August, 1889, at which time his weight was 106 pounds. In this seizure the fingers and hands became shaky, and this was soon followed by general tremors of the body and lower extremities. His appetite was not impaired. At night his sleep was disturbed by dreams of a horrible character and by involuntary muscular twitchings. In talking, his tongue felt thick and he had but little control over its movements. His speech was muffled and at times barely intelligible. Sensation was not impaired. In walking down stairs he experienced considerable difficulty and had a constant fear of falling. He could ascend a flight of stairs all right. In seven weeks he returned to work, but was obliged to quit in a little over a month's time. At the suggestion of a physician, he went to the seashore and indulged in sand-baths. He improved and returned to work, at which he continued until November, 1889. At this time most of his trouble was due to his ataxic gait, though he was still affected by the general tremors. In this attack, his eyesight annoyed him considerably. In reading, letters appeared blurred and would run together. His memory failed. The appetite remained unimpaired—if anything, exaggerated and capricious, although he suffered from indigestion. The bowels were costive, but were regulated by taking a cup of hot water every morning. The gums became quite sore and the teeth loose. In December, 1889, he came under my observation, at which time his condition was as follows: He was fairly well-proportioned; there were general tremors of the body and a marked ataxic gait—the feet seeming to drag along the ground when patient attempted to walk; the strength in the hands was about normal. The breath was fetid, the teeth loose, the gums spongy; upon protrusion, the tongue was quite tremulous; the speech thick and guttural; there was no ankle clonus; the knee-jerk was exaggerated upon both sides, and upon being told to extend the index finger and forearm and to bring the tip of finger to the edge of nose, he was able to do so only after fumbling over face. The lungs and heart were normal.

Case IV.—Martin V., sixty-three years old, married, also occupied in the manufacture of hats, presented himself for treatment January 10, 1890. His previous history was to the effect that he had always been healthy. He was married at the age of thirty-two. He had always been a steady man, had never used liquor to excess, though, like most Germans, he indulged in his glass of beer. He chewed tobacco freely, but seldom smoked. He denies any indulgence in venery until after marriage. He came to this country in 1854, at the age of twenty-seven. In 1870—twenty years ago—he commenced work at his present occupation. For eleven years, or thereabouts, he worked at heating the irons with which the hats are burnished. During this time he felt well, with the exception of a constant cramp in the muscles of the calves of legs. He was then transferred to the fur department, where he helped

to mix the solution of quicksilver and acid used to preserve the fur, and also to pack the fur into five-pound parcels. Soon after entering upon the duties of his new occupation he became dyspeptic and he noticed that his salivary secretion was freer than usual. He also had a disagreeable, metallic taste in the mouth. At the expiration of two years he felt unsteady in his movements, and had slight twitchings of the muscles of the face and upper extremities. His gums also became swollen and sore. Later on, these feelings increased in intensity and were soon followed by tremors, first noticed in the arms, then in the legs, and finally, the ataxic movements became general. He was obliged to quit work, as he could not feed nor dress himself. Under treatment he improved, and returned to the factory. The attack on account of which he sought advice had begun one week previously. The legs became heavy and felt like lumps of lead; the hands and arms became tremulous, the appetite poor and he complained of a constant drowsy feeling. He has had no diarrhea and never has been otherwise than regular in respect to movements of the bowels. He was well-preserved for one of his years. His gait in walking is best described as ambling. The arms were ataxic and it was impossible for him to bring suddenly the tip of the index finger to the end of the nose. The knee-jerk was rather below the normal. No ankle-clonus was present. The teeth were in poor condition, loosened and very much darkened, although the patient affirmed that he had taken good care of them. There was no line upon the gums. The breath was fetid, and there were evidences of salivation. The tongue was tremulous upon protrusion, and he complained of considerable temporal headache.

CASE V.—John K., eighteen years old, employed in the same business as the other patients, came under my care in December, 1889. He did not seem to possess an over-bright mental faculty. Two and a half years previously, he started to work at manufacturing hats; he stated that at that time his physical health was good. Seven months previously he began to feel the effects of the work. His hands became unsteady and tremulous, and a month later his feet were similarly affected. The gums became sore and swollen, and salivation ensued, but the teeth did not become loosened. The memory was impaired. He was obliged to quit work two weeks before he came under my observation. The gait was markedly ataxic; upon standing or sitting, his movements were not unlike those seen in a bad case of major chorea. The tongue upon protrusion was quite tremulous, and mercurial fetor of breath was very noticeable. The gums were spongy, red and quite sensitive; the knee-jerk exaggerated, and the ankle-clonus absent.

1610 ARCH STREET.

"GENTLEMEN, I want you to *love* pathology, for pathology will teach you the morbid processes which govern the body as physiology does the normal, and you must be able to watch these morbid processes from beginning to end; if not, you cannot understand disease; if not, you will be like a sailor without a compass."—DR. H. G. SUTTON.

TYPHOID FEVER WITH LOW TEMPERATURE.[1]

With Remarks as to its Probable Cause.

BY H. L. JENCKES, M.D.,
OF HAZEL GREEN, WISCONSIN.

IN a lecture[2] at the Philadelphia Hospital, Dr. James C. Wilson divided *atypical typhoid fever* into the following classes: (1) mild typhoid; (2) abortive typhoid; (3) typhoid of childhood; (4) typhoid of the aged; (5) cases of febrile intestinal catarrh; and (6) cases of afebrile intestinal catarrh. It is to this last and rare form that I would direct attention.

A case of this kind occurred in a child about ten years of age.[3] When first seen he had been unwell for several days. He complained of headache, his bowels were constipated, and he was slightly feverish at night. During the first six days of treatment there was continuous fever, with a gradual rise of temperature until 103.5° was reached. His pulse was full, strong, and moderately rapid. Marked looseness of the bowels now set in, with some tenderness in the region of the ileo-cecal valve. On the seventh day of treatment, and about the tenth day of his illness, the temperature began to decline and soon dropped to 101°—a fall of 2.5°. As the patient had not been overwhelmed with quinine, or any of the antipyretics, it could hardly have been the result of treatment. During the next three days there was a still further decline of temperature until 98° was reached. Rose-colored spots appeared upon the abdomen, and there was marked tenderness in the region of the ileo-cecal valve. The tympanites was at times marked, and the discharges from the bowels, which remained loose, frequently contained blood. The duration of the illness was about four weeks, and during most of this time the patient's temperature was from 98° to 99° with all the other symptoms of typhoid fever well marked.

This case, with others that have been published, tends to prove that elevation of temperature is not absolutely invariable in cases of typhoid fever, although, excepting in mild cases, it is generally believed to be so. In looking over the literature of the subject at hand, I can find but few cases reported. Fräntzel[4] reports 11 cases of typhoid fever which attacked exhausted individuals, and in which there was low temperature or absence of fever, but in which there were general collapse, serious cerebral symptoms, and a tendency to gangrene of the extremities, which ran a strikingly acute course. Such cases indicate that high temperature is not

the only cause of death in typhoid fever, but that cerebral symptoms are of great importance, and that, even with low temperature, patients must be carefully watched to prevent them from the many evil consequences of even quiet delirium. In the article on typhoid fever in *Ziemssen's Cyclopedia*, Liebermeister[1] mentions cases in which the temperature was not high, but such cases are classed as mild. He attributes more significance to the character of the temperature than to any other symptom of the disease. Professor Flint[2] says: "More or less increase of the heat of the body is invariable. The rule that during the greater part of the disease the temperature is raised, is without exception; but under certain circumstances the heat may not exceed, and it may even fall below, the standard of health."

In a review of the *Transactions* of the Academy of Medicine in Ireland,[3] I find the following:

"Mr. J. V. Lentaigne's case of fatal peritonitis, following perforation of an ulcerated small intestine, is of very great value with reference to the diagnosis of enteric fever and the occurrence of afebrile cases of that disease. The patient from whose body the specimens were taken came from a notoriously unwholesome tenement, in which thirty-three persons lived in eight apartments. Seven deaths had recently occurred, and one man was then sick abed. Furthermore, the main sewer of the street had been for some weeks open. The man had been ill for about a fortnight and had been refused admission to three hospitals. When received into the Jarvis Street Hospital, although manifestly ill, his temperature was normal, and the difficulty in diagnosis appeared to be due to this fact. The autopsy discovered the lesions of enteric fever."

The writer of this review (James C. Wilson) has elsewhere insisted upon the fact, too little recognized, that enteric fever may run its course not only without the typical temperature of Wunderlich, but even with a subfebrile temperature; and in certain rare cases, the nature of which is established by the complexus of symptoms and the coexistence of house epidemics, actually without any rise of temperature at all. It is a quibble to say that such cases are not enteric fever. They are the specific enteric disease of which the usual fever is merely one of the prominent, but not therefore always essential, symptoms. Professor F. C. Shattuck expresses a similar opinion.[4] He says: "It seems to me that there is absolute proof that typhoid fever may exist and even prove fatal without the presence of fever." And Strube[5] has reported 14 cases of typhoid fever in which the temperature was normal or subnormal. These cases occurred among the German troups besieging Paris.

In attempting to account for such cases, it will be necessary to refer briefly to the etiology of typhoid fever. The typhoid bacilli seem to flourish chiefly—or perhaps only—when they find lodgment in the small intestine. The idea that the disease can originate by the inhalation of this pathogenic organism is extremely doubtful. Finding lodgment in the lymphoid follicles, the bacilli not only rapidly multiply, but produce ptomaïnes. Soon the bacilli are carried by the lympathics to the mesenteric glands; from these glands they seem to penetrate into the blood, and finally find lodgment in the spleen, liver and kidneys. The effect of the bacilli, and of the putrefactive process that their rapid multiplication soon produces upon the system, is to produce, first, a toxemia; secondly, a septicemia by causing abscesses in the glandular structures; they may produce a pyemia. It is possible that a toxemia can exist without elevation of temperature, since it is well known that the susceptibility to toxic agents differs greatly in different individuals. Although difficult to explain,[1] this undoubtedly plays an important part. It may perhaps be owing to a greater or less degree of vitality inherent in all cellular and tissue elements. To better illustrate this principle of susceptibility, one might say that yeast produces alcohol, and the absorption of a certain quantity of alcohol produces intoxication. Nevertheless, the absorption of this fixed quantity of alcohol will not produce intoxication in every individual. A case, reported by Professor Rossbach[2], has a corroborative bearing on this question. The patient, he states, was receiving naphthalin for the treatment of typhoid fever. During fifteen days the fever was entirely absent; but no sooner was the remedy suspended than the temperature rose. Professor Rossbach does not claim that naphthalin reduced the fever, but thought that by counteracting the putrefactive process in the intestine the source of the fever process was removed.

It seems therefore not improbable that a toxemia may exist in an individual whose system is so little disturbed by the toxic principle (the ptomaïne) that the usual symptom of fever does not occur. From this study of the subject the following may be deduced:

1. The typical temperature of Wunderlich does not occur in all cases of typhoid fever.

2. That even severe cases are occasionally seen

[1] "It may mean some slight difference in the chemical constituents of the body, the excess of some element that is noxious to the development of the bacteria in question, or the deficiency of some substance that is necessary for their vigorous growth." W. Watson Cheyne in the American Journal of the Medical Sciences for January, 1887.

[2] See the Therapeutic Gazette, January 15, 1885.

in which the temperature does not exceed the normal.

3. That it is unnecessary, and may even be hurtful, to direct the treatment solely to the reduction of the fever. (This refers to *antipyretic remedies*, and has *no* reference to the Brand system of cold baths, the beneficial results of which are confirmed by Ziemssen, Jürgensen, and by members of the Lyons school in France.)

4. If it be true that the introduction of the typhoid bacilli into the system and their rapid multiplication cause putrefaction, and if the absorption of this putrefaction-material produces the phenomena of typhoid fever, then of course it follows that the *early* administration of remedies that will keep the intestinal canal in as nearly an aseptic condition as possible seems imperatively indicated.

CLINICAL MEMORANDUM.

A NOTE ON FLUORESCIN-COLORING AND THE ACTUAL CAUTERY IN CORNEAL ULCERS.

By G. E. de SCHWEINITZ, M.D.,
OPHTHALMIC SURGEON TO THE PHILADELPHIA AND CHILDREN'S HOSPITALS.

As is well known since the publications of Straub, Thomalla, and Fromm-Groenouw, a concentrated, two per cent. alkaline solution of fluorescin colors green any portion of the cornea deprived of its epithelium, while the healthy epithelium remains unaffected. At first this discovery seemed devoid of practical value, but it soon acquired diagnostic worth in detecting minute abrasions of the corneal surface, particularly when these were of traumatic origin. Perhaps its most important use has recently been suggested by Nieden (*Centralblatt für praktische Augenheilkunde*, May, 1891), in connection with its value as an aid to the actual cautery in the treatment of ulcers of the cornea. This earnest advocate of the galvano-cautery in ocular therapeutics has more than once lamented the lack of exact means for determining how extensive should be the application of the glowing point of the instrument. In his last communication upon this subject he pointed out that he was rarely obliged to resort a second or third time to the use of the cautery, but in the very first instance succeeded in applying the heated needle to the entire area of ulceration, in spite of the fact that he was without a method of outlining with absolute certainty the entire area which required destruction. This means is now at hand in the form of fluorescin, because, by its use, the border between the sound and the diseased area can be demonstrated with exactness. More than this, the depth of the ulceration and any outlying areas of infiltration deprived of their covering of epithelium are indicated by the green coloration. In common with a number of observers, I have often made use of fluorescin for the purpose of staining deep and superficial ulcerations of the cornea, and of demonstrating the rate of progress in the healing of any corneal ulceration, and the presence of minute foreign bodies imbedded in the surface of this membrane. Quite recently, acting on the suggestion of Nieden, I have employed it in several cases of ulcer of the cornea, to which, afterward, the glowing point of a thermo-cautery was applied. Two cases will illustrate its value.

Case I. (Philadelphia Hospital.)—An adult with chronic trachoma: on the left side, in the stage of cicatrization; on the right side, in the stage of ulceration of the follicles, with pannus. This eye, owing to exposure, took on a violent form of keratitis with dense pannus in the upper portion of the cornea, while in the lower half there appeared an irregularly crescent-shaped ulcer with sloping margins and outlying spots of infiltration. The entire cornea exhibited the well-known whitish infiltration so common in this disease. The manipulation was as follows: An application of a few drops of a two per cent. solution of fluorescin (Gruebler's fluorescin 2 per cent.; carbonate of soda 3.5 per cent.) was made to the affected eye. The entire crescent-shaped ulcer was colored a deep green, and, still more interesting, three of the more saturated whitish areas of infiltration situated in the general haze of the cornea acquired a similar color. This at once became the guide for the proper application of the actual cautery. The ulcer itself and the three superficial spots were cauterized, or, in other words, all those spots which had been stained green were subjected to this treatment. It seems to me, in a case of this character, that the three smaller areas certainly would have been overlooked without the use of fluorescin, and their character of superficial ulceration undetected, owing to the obscuration produced by the general haze and development of vessels in the cornea.

Case II. (Children's Hospital.)—A child of about five years of age, with an ordinary phlyctenular keratitis, in the course of which a phlyctenular ulcer appeared below the centre of the cornea. In this stage the child was admitted to the wards, and the following manipulation performed: A few whiffs of ether were given to quiet the little patient, and the point of the cautery applied to the somewhat irregular ulcer and its slightly infiltrated margins. The eye was now washed out with boric acid lotion and a few drops of the fluorescin solution applied. It then became manifest that all ulcerated spots had been destroyed with the single exception of a small portion of the upper and inner margin, slightly distant from the main body of the ulcer, which at once assumed a deep-green, characteristic color. A second light application of the cautery to this spot destroyed the previously untouched area.

Nieden calls attention in his communication to the very points which are illustrated in these two cases selected at random. He dwells particularly upon the fact that in serpentic ulcer of the cornea, beyond the well-known half-moon-shaped area of propagation, one or two small, sharply marked spots of infiltration are commonly present, but, owing to the diffuse opacity of the border-zone of the ulcer, not readily detectable, unless they are colored green by the instillation of fluorescin. Every surgeon must have seen a phlyctenule start at the border of the cornea, break down into an ulcer, push its way toward the centre with an advance guard of infiltration and a rear guard of densely injected vessels, and with a strong tendency to perforate, or at all events to form a stubborn type of keratitis, which, on heal-

ing, leaves a disfiguring stripe of opacity. In such a case a drop or two of the fluorescin mixture will accurately outline the extent of the ulcerated infiltration and give exact information as to where the point of the cautery should be applied, but more than all, as to what extent the destruction of the tissues should be carried.

ORIGINAL LECTURE.

ACUTE ARTICULAR RHEUMATISM COMPLICATED WITH ACUTE ENDOCARDITIS—TYPHOID FEVER,

With Two Relapses and other Complications.

A Lecture delivered at the Philadelphia Hospital.

BY JAMES M. ANDERS, M.D.,
PROFESSOR OF CLINICAL MEDICINE, MEDICO-CHIRURGICAL COLLEGE; VISITING PHYSICIAN TO THE PHILADELPHIA AND EPISCOPAL HOSPITALS.

GENTLEMEN: The patient, an unmarried carpenter, twenty-eight years old, gives a maternal family history of rheumatism. He had scarlet fever and diphtheria in childhood. Seven years ago, he had an attack of articular rheumatism. He admits a history of syphilis. Toward the close of December, he noticed stiffness and soreness in his knee-joints, following exposure—working in the snow. In the course of a day or two his shoulder-joints became affected, and soon the wrist-joints were painful and swollen. In a few days there was some improvement, but subsequently the joint affections again grew worse. On the day of admission the patient was able to walk, though the wrist and shoulder of the left side were swollen and painful. The temperature was 102°. He was given salicylate of sodium, and defervescence soon followed, with improvement in the condition of the joints. A few days later the cardiac impulse was observed to be increased in extent and displaced in location.

The heart beat strongly but regularly, but there was no change in the condition of the pulse at the wrist at this time—an important fact to bear in mind in connection with the cardiac complications of acute articular rheumatism. A soft, blowing, systolic murmur, with slight prolongation of the first sound, was heard with greatest distinctness over the base of the heart and transmitted into the carotids. A day or two later there was detected at the apex of the heart, a soft, systolic murmur, heard most distinctly at the base, not transmitted to the left or to the angle of the scapula, but transmitted into the carotids. The physical signs indicated the existence of an acute exudative endocarditis, though there may have been an interstitial endocarditis. The cardiac percussion-dulness extends beyond the nipple line; the impulse also extends beyond the line of the nipple. The diagnosis of acute endocarditis cannot be positively made in the absence of a systolic murmur, though endocarditis may exist and pass through its various stages without the detection of a murmur. In such a case the alteration in the seat of the impulse, on inspection, and the variability of the seat and intensity of the impulse, on palpation, are evidences of the existence of the inflammation. If chronic interstitial endocarditis already exists, the diagnosis is difficult. When an acute endocarditis is engrafted on a chronic endocarditis, the area of cardiac percussion-dulness is augmented. In the first stage of pericarditis we hear a to-and-fro friction-sound close to the ear, not always synchronous with the action of the heart and not propagated beyond the precordia. In endocarditis the murmur seems more distant; it is heard most distinctly at the apex and with the heart-sounds. In pericarditis the murmur is heard most distinctly at the base. In the second stage of pericarditis, when effusion has taken place, the area of cardiac dulness is increased and of pyramidal shape, the base below, the apex above, and extends a little to the left of the nipple line; the friction-sound heard in the first stage is absent. In endocarditis the area of cardiac dulness is unaltered; in pericarditis the heart-sounds are heard distinctly at the base, though feeble, muffled, and distant at the apex; the impulse is more extensive than in health. Other complications may arise in the course of articular rheumatism. Bronchitis occurs in about 16 per cent. of cases; pneumonia and pleurisy may develop. Pleurisy with effusion is more apt to occur when pericarditis is the primary affection; pneumonia occurs with both pericarditis and endocarditis. General pulmonary congestion may manifest itself suddenly and terminate fatally; not infrequently, in the course of articular rheumatism, death takes place from catarrhal pneumonia. The polyarthritic affection may be mistaken as pyemic; the previous history will aid in clearing up the diagnosis. When pyemia exists, there is a history of injury or abscess or of infectious disease; there are repeated rigors, the temperature suddenly rising to 104° or 105° within an hour, declining by crisis, or with sweating during the remission. In rheumatism there are well-marked exacerbations of fever; the temperature may be high but is sustained, and defervescence is not sudden, while the sweating often continues as long as the fever. The visceral complications of pyemia are different from those of rheumatism; there may be endocarditis and pneumonia, but abscesses of internal organs are common. Pyemia is rather rapidly fatal; rheumatism is not. In pyemia the local affections are not so well marked. In rheumatism the joints have a glossy appearance and the tenderness is in the synovial membrane; in pyemia the tenderness and swellings are more apt to spread above and below the joints. In rheumatism the articular invasion is erratic; in pyemia it is not, though sometimes two or more joints are affected. The points of distinction between rheumatism and glanders need merely be alluded to: glanders usually occurs in those engaged in handling hides or wool; the joint affections occur only in the early stage; later, a typhoid state is developed, with blebs on the skin and subcutaneous abscesses.

The prognosis of articular rheumatism is favorable; the mortality is from 3 to 5 per cent., and is largely dependent upon the visceral complications; the heart complications are apt to lead to chronic incurable conditions.

In this case salicylate of sodium was given in doses of 20 grains every two hours, for twelve hours; during the next twelve hours alkaline treatment was pursued. Salicylate of sodium sometimes aggravates the heart complications; alcoholic stimulants should then be resorted to. If unpleasant symptoms persist, the salicylate should be

withdrawn and the alkaline treatment substituted. Alkalies prevent the visceral complications of acute rheumatism, salicylate of sodium does not. The alkalinity of the blood is maintained by the vegetable acids, so that these may be exhibited as soon as the temperature has fallen several degrees. Quinine may be given in does of 2 grains every four hours. Opium, in small doses (gr. $\frac{1}{10}$ of the aqueous extract), exerts a favorable influence in acute endocarditis and gives relief from pain; laudanum with an alkali applied locally as a lotion gives relief. Before the temperature has fallen to the normal, iron should be given in acute endocarditis to overcome the anemia. The following is a favorite prescription:

℞.—Ferri et ammon. citratis . . . ʒij.
Tinct. gentianæ comp. . . . ʒij.
Glycerini . . . . . ʒj.
Aquæ . . . . q. s. ad ʒiv.
Sig.—A teaspoonful, diluted, every three hours.

When there is reason to believe that the myocardium is affected in any degree in acute endocarditis, digitalis ought not to be given. The temperature of the room should be kept at between 68° and 72°.

The second case is that of a mulatto girl, twenty-three years old, admitted to the hospital with low delirium; when her mind cleared she stated that she had been ill six weeks previously. The left popliteal space was now swollen, evidently from venous thrombosis, a result of a sluggish circulation. Her tongue was furred, but red at the edges; the abdomen was tympanitic; there were pain and gurgling in the right iliac fossa and diarrhea. At the bases, posteriorly, the percussion-resonance was impaired, and the respiratory murmur was enfeebled; moist râles were heard over the same regions—a result of the feeble circulation. The pulse was small, thready, and hurried; the temperature 104°. She was given quinine, gr. ij., every four hours, by suppository; carbonate of ammonia, gr. v., every three hours, with alcoholic stimulants internally and poultices to the thorax; liquid diet. The abdominal symptoms and the general condition improved; it was thought the patient was passing through the third stage of typhoid fever, when intestinal hemorrhage took place, the temperature rapidly falling, the blood, however, not escaping until twenty-four hours later, when sixteen ounces of dark clotted blood were passed. When intestinal hemorrhage occurs in the course of typhoid fever the temperature falls at the time of bleeding, although the blood, as a rule, does not escape at once. Always suspect this complication when there is a sudden decline of temperature of 3° or 4° F. When intestinal hemorrhage occurs early in the course of typhoid fever it is due to congestion; the epistaxis results from the same cause. When intestinal hemorrhage takes place during the third week, it is due to the opening of a vessel by the ulcerative process in the bowel. After the temperature had fallen below normal, in another day it arose again; two days later another hemorrhage took place and was followed in the course of twelve hours by the evacution of thirty ounces of a dark-brown, watery fluid. The temperature remained depressed after the second hemorrhage and did not rise again; the patient passed into a state approaching collapse, with pinched countenance, feeble pulse and moist skin. When intestinal hemorrhage occurs in the third week of typhoid fever, a condition simulating perforation may develop, with pallor, weak pulse, moist skin, but without pain. When perforation occurs symptoms of peritonitis are developed, with swelling of the abdomen, great tenderness on palpation, rapid pulse and pain. The temperature of the patient had been subnormal for nearly a week, when she ate some candy and fruit, after which the symptoms of relapse appeared. It is generally stated that relapses in typhoid fever do not result from errors of diet, but from a predisposition on the part of the system—in other words, some virus remains latent until its development is excited. The course of a relapse is different from that of the original attack: the onset is sudden and the stage of high temperature is of shorter duration. Certain complications may arise during a relapse. In this case there was developed, over the outer side of the os calcis, enlargement of the bone, localized pain and tenderness, not dependent on thrombosis, but upon periostitis—a rare sequel. As a rule, it is not followed by necrosis. Hemorrhage may occur during a first relapse, but it is rare during a second. The finger-nails become marked by a white line for each attack.

CURRENT LITERATURE.

HAY-FEVER AND EXCESSIVE SNEEZING.

DR. J. E. BULLOCK (*The Provincial Medical Journal*, June 1, 1891) presents a timely paper on the subject of "Hay-fever and Excessive Sneezing." In the treatment of hay-fever the first indication is to improve the general health; as the disease is exhausting, the patient should avoid over-fatigue and should take a nourishing diet; alcohol in any but a moderate amount is to be avoided, as it increases the nasal hyperemia that conduces to the disease. Coffee, as a stimulant, is particularly useful in the asthmatic form, as it is in ordinary bronchitic asthma.

Those who are able should move away from the source of irritation, and in most cases a residence at the seaside, where there is a prevailing wind from the sea, or a sea-voyage, well away from land, is the best means of escaping the irritation. At home, the patient will avoid proximity to pollen grains, and will protect his eyes, either by wearing "goggles" or by staying in-doors in the middle of the day; a veil of "double gossamer" will protect both his eyes and his nose from pollen irritation. In relieving the attacks, opium and belladonna have been found most useful, acting probably by reducing the secretion and diminishing irritation. Tincture of opium, either with or without tincture of belladonna, may be given in five-drop doses twice a day or one-twentieth of a grain of morphine and one-two-hundredth of a grain of atropine, night and morning. Belladonna may be found useful in those cases in which there is irritation in the roof of the mouth, but cocaine lozenges are generally more useful. In persons of nervous temperament the pill of valerianate of zinc and asafetida, as recommended by Sir Morell Mackenzie, is useful as a nerve tonic, to be taken a month or so before the hay season begins. Bromide of potassium and nux vomica will also allay nervous excitability. Antipyrin (ten grains twice a day) has been recommended as an anesthetic to the sensory and secretory nerves of the nose. A solution

of corrosive sublimate (1 : 3000) may be used as a preventive lotion, both to bathe the eyes and also for the nose, either as a spray or by mopping the nostrils with a pledget of cotton-wool. If not too sensitive, the nostrils may be plugged with cotton-wool saturated with the same solution. For the irritation of the eyes, a mild astringent collyrium (such as two grains of acetate of lead in an ounce of rose-water) will give relief. If the itching of the eyelids is troublesome, it will be well to bathe them with a solution of acetate of morphine (two grains to the ounce of water). A drop of a solution of morphine ($\frac{1}{4}$ gr.) and atropine ($\frac{1}{150}$ gr.), dissolved in thirty drops of water, placed in the eye at intervals will afford great relief. Tobacco-smoking is a useful preventive; cigarettes of cubebs are highly extolled by some. Ordinary anti-asthmatic remedies will be found most effectual to relieve the difficulty of breathing. Fumes of niter-paper or of stramonium should be inhaled; the latter may be used either as a dry powder, mixed with other dried herbs, or smoked in a cigarette. Treatment applied to the nose is the main indication in hay-fever, and with the exception of cocaine, all applications should be more or less astringent. A 10 or 20 per cent. solution of the hydrochlorate of cocaine is of service in allaying the irritation accompanying hay-fever, but it should not be too long persisted in. As it soon loses its effect, the strength must be increased, and the subsequent hyperemia leads to an aggravation of the symptoms. Cocaine may be applied either by a spray or on pledgets of cotton-wool. Cocaine lozenges (gr. $\frac{1}{10}$) may be sucked occasionally, especially to allay the itching in the roof of the mouth. Hollow nasal bougies containing cocaine are sometimes useful, but may be too irritating to the hypersensitive mucous membrane. As a substitute for cocaine, menthol (in 10 per cent. or 20 per cent. solution in almond oil, and applied in the same way as cocaine) may be used. An ointment of eucalyptus (one dram to an ounce of vaselin) is a useful sedative ointment.

Insufflations into the nose are sometimes useful. Morphine in some combination is the best powder to use. Acetate of morphine (gr. $\frac{1}{16}$ to $\frac{1}{8}$) may be used either with powdered starch (gr. $\frac{1}{2}$) or bismuth (gr. 1). In the same way ordinary snuff may be taken by men. Strong smelling-salts will sometimes ward off an attack, but only when the irritation is slight. A solution of chromic acid ($\frac{1}{16}$ grain to an ounce of water) is useful as an astringent. The whole interior of the nose should be freely swabbed, or the solution may be sprayed into the nostrils; the application is painful, and cocaine should be used.

In cases of hay-fever the nose should be examined. Certain sensitive spots may be found which excite sneezing on the slightest irritation. These should be treated with the galvano-cautery. A deviation of the septum may require remedy; an exostosis or an enchondroma or excess of tissue, removal.

PATHOLOGICAL CHANGES PRODUCED BY TUBERCULIN.

At the Congress of Internal Medicine, at Wiesbaden, Ziegler, of Freiburg (*Centralblatt f. allg. Path. u. path. Anat.*, Bd. ii., 1891), for Birch-Hirschfeld, presented a pathologico-anatomical discussion on—(1) The changes produced in tuberculous organs by the injection of tuberculin. (2) The question whether these changes led to the healing of the tubercle or to its diffusion or isolation within the tissues. (3) The extent to which previous investigations had proved the healing powers of the injections. He maintained that there can be no doubt that, as a result of the injection of tuberculin, inflammation is set up in the tissues separating and surrounding the tubercles. The degree of inflammation is variable, in some cases being limited to a simple effusion of serum, whilst in others there may be much cellular proliferation, or even suppuration. The inflammation may subside and its products be absorbed. The bacilli are not destroyed, even in the inflamed areas. If the tubercles be situated on the surface, they may be disintegrated and thrown off by the inflammatory process around them, ulcers being left in their stead. The bacilli are not all discharged with the tuberculous material, but may find their way into the neighboring lymph-passages. Tubercles situated beneath the surface, after being disintegrated by the inflammation around them, are either absorbed or encapsulated. The conversion of the tubercle into organized tissue is not possible so long as the bacilli within it are not destroyed, but if the tubercle be disintegrated and absorbed, it may be replaced by organized tissue. Absorption of disintegrated tubercle is, however, accompanied by absorption of the contained bacilli; these may find their way into the lymph-channels, the bloodvessels, or the air-passages, according to the situation of the tubercle. It is therefore reasonable to conclude that the disintegration of the tubercle may lead to the escape of bacilli, but it does not follow that this escape must in all cases give rise to the metastatic formation of tubercles. The bacilli may be rendered incapable of further development by the chemical or other properties of the tissues into which they have made their way. There is no reason to suppose that any immunity is conferred upon the tissues by the injection of tuberculin. If the tubercles become encapsulated, without resorption, even though they still contain bacilli, they are less harmful than those that undergo disintegration. That an actual process of healing is to be observed after the injections of tuberculin is undoubted, and may especially be noted in mucous membranes. It must not be forgotten, however, that inflammatory processes around and about tuberculous nodules are of very common occurrence. They are particularly well marked in intestinal tuberculosis, but may be seen also in the deeper parts of the lungs and other organs when resorption of the actual tubercle has taken place. The changes induced by tuberculin are, in fact, only those that may occur in the natural course of tubercle, but they are brought about more violently and more rapidly and in situations in which in the ordinary course of events they would never occur. Dr. Ziegler expressed the view that both the healing properties and the dangers of the injection-treatment have been overrated. In many of the cases under treatment in which the disease has increased a similar result would soon have occurred independently of the injections, but it is highly probable that in some cases the inflammatory changes following the injections have favored the spread of tubercle. Many observations go to prove that a marked development of bacilli may take place in tubercles undergoing this inflammatory disintegration,

and that in such cases the danger of the escape of bacilli into other tissues is considerable. The action of tuberculin is always limited, and in a case of diffuse tuberculosis is not universally manifest. It would appear that some special conditions of the peri-tuberculous tissues are requisite for the determination of the inflammatory changes. No instance has yet been observed in which as a direct result of the action of tuberculin a tuberculous nodule has become encapsulated.—*Supplement to the Brit. Med. Journ.*, June 27, 1891.

MEDICAL PROGRESS.

Traumatic Detachment of the Placenta.—BOGORODITZKY (*Proceedings of the Tambow Medical Society*, Nos. 9, 10 and 11, 1890) reports the case of a healthy woman, twenty years old, in the fourth month of pregnancy, who, one night, "for amusement," threw a somersault in bed. Immediately after, she was conscious of pain in the abdomen, which moderated, and the woman fell asleep. On the next morning, however, she awoke with increased pain, a feeling of weight in the abdomen and general prostration. Soon there set in obstinate constipation (that did not yield to enemata or purgatives), violent vomiting, fever, dysuria and retention of urine. Two weeks later she appeared anemic and collapsed; the pulse was quick and weak, the abdomen distended and tender, the uterus flabby, its fundus reaching about three fingers' breadth above the umbilicus, the cervix displaced backward, the os admitting a finger. Intra-uterine hemorrhage being diagnosticated, hot vaginal douches were given, an ice-bag applied to the abdomen, ice, stimulants and ergot administered. At the end of four hours a dead four-months' fetus was expelled; but the uterus remained as large as ever. On further examination, the organ was found to contain a smooth, globular body, of the consistency of the placenta. The membranes and placenta being ruptured, the finger entered an enormous cavity filled with an immense volume of fluid and clotted blood. After the removal of the membranes, clots and blood, the uterus contracted and hemorrhage ceased. The after-treatment consisted in hot, disinfectant irrigations and the internal administration of ergot and quinine. Notwithstanding the formidable loss of blood, an excellent recovery followed. On the fourth day the temperature was normal; on the tenth day the patient got out of bed.—*Provincial Medical Journal*, July 1, 1891.

Intravenous Injections of Soda in Anemia.—CASTELLINO (*Gaz. d. Ospit.*, No. 20), at the clinic of Maragliano, at Genoa, has studied in cases of anemia the results of intravenous injections of from fourteen to sixteen ounces of a ¾ per cent. filtered solution of soda. The injections were well borne, though sometimes followed by slight fever. An hour after the injection the number of red cells and the percentage of hemoglobin were reduced. This oligemia was transitory and proportional in degree to the quantity of fluid injected. At the end of from ten to twenty hours a decided increase in the number of blood-plaques and in the number and resistance of the red cells had taken place; the red corpuscles were, however, still pale; the hemometer detected little variation. In the course of four or five days the increase in the number of red cells became more conspicuous, the percentage of hemoglobin remaining stationary. During this period the red corpuscles showed greater resistance to the serum than they did previously. At the end of from thirty to forty days the good effects of the injections had disappeared. In three cases the serum, which before injection had, on spectroscopic examination, contained a considerable quantity of hematin, became clear after injection. In a case of chronic malarial fever of quotidian type the injection was followed by a decline of 2° in temperature. Good results attended the injections in a case of intense chloremia and in one of purpura simplex. In both, the number of red corpuscles became doubled, the general condition improved, and there was an increase in body-weight.—*Wiener klinische Wochenschr*, June 4, 1891.

Sacral Hysterectomy.—TERRIER (*Wiener med. Presse*, July 12, 1891), at the French Congress of Surgery, reported two cases in which he performed sacral hysterectomy. One was in a woman fifty-two years old, with extensive carcinoma of the body of the uterus, and with a narrow, resistant vagina. Vaginal extirpation was out of the question, so that the uterus was removed by the sacral method. The woman recovered without a recurrence of the neoplasm.

The second case, in a woman fifty years old, with intra-uterine carcinoma, terminated fatally. Terrier emphasizes the fact that the ureter is more likely to be injured in sacral than in vaginal or abdominal hysterectomy. He considers vaginal hysterectomy the normal operation, and the sacral method as indicated only when the vagina is narrow and not distensible, when the uterus is voluminous, and when lateral adhesions exist or the broad ligaments are carcinomatous. The operation is a difficult one.

ROUX considers the sacral operation only exceptionally indicated, to be reserved for massive carcinomata. By performing temporary resection of the sacrum, injury to the ureters is not possible. Of ten cases operated on, Roux has lost but one, in which a removal of portions of the bladder and ureter was necessary.

Congenital Rickets.—At a meeting of the Section on Orthopedic Surgery of the New York Academy of Medicine, DR. T. HALSTED MYERS presented a case of marked rickets, in which it was stated by the mother that the greatly enlarged epiphyses of the tibiæ, femora and radii were present when she first examined the child a few days after birth. The sternum at that time was also abnormally prominent. The mother had been in good health during the gestation; the father was also healthy. No specific history could be obtained. The child, six years of age, presented all the deformities of rickets in a marked degree, except that the head was well shaped and that there was a marked increase of the normal dorsal curve of the spine, rather than the dorso-lumbar kyphosis usually found in these cases. An unusual degree of permanent knee and hip-flexion also existed, and the patient, when resting, assumed the hand-to-knee position of Pott's disease. The epiphyseal tenderness seemed to indicate an active stage of the disease. After being nursed nine months, the child had a mixed diet, not especially starchy or lacking in animal fats.

Philadelphia.

SATURDAY, AUGUST 15, 1891.

THE CONGRESS OF TUBERCULOSIS.

In another part of the current number of The News will be found a preliminary report of the recent Congress of Tuberculosis, held at Paris. If there is one thing, above all others, to be learned from the many discussions upon the well-worn but still obscure subject of tuberculosis, it is that the bacillus alone does not constitute the disease. The host is obviously not the least important element. That human tuberculosis is not inoculable in all animals, and that all susceptible animals are not equally susceptible, must be a sufficient demonstration of this point. As the bacillus thrives well or ill on various artificial nutrient media, so in the animal organism does it require a suitable soil for its growth and development. What these conditions are, as well as what part the bacillus directly plays, and what influence the products of its vitality exert, we do not as yet know. These are all matters for further investigation.

Prudden and Hodenpyl (*New York Medical Journal*, June 6 and 20, 1891) have demonstrated that dead, sterilized tubercle bacilli injected into rabbits are capable of setting up a process apparently identical with miliary tuberculosis, but unattended with the retrograde changes that result in caseation and softening. We do know, however, that we can accomplish most in the treatment of tuberculosis by improvement of the general nutrition, and it is universally admitted that the accomplishment of this end is facilitated and promoted by a suitable selection of climate for residence.

We do not mean to belittle the significance of the bacillus of Koch in the etiology of tuberculosis, but desire to emphasize the importance of other conditions that must be considered as concomitant and not as secondary or subordinate.

"The prophylaxis of tuberculosis must begin before birth." The system must be rendered impregnable to the invasion of a disease-agent that is practically omnipresent. The invasion once accomplished, the struggle is an unequal one; the enemy once intrenched, his expulsion is a matter of difficulty; the only hopeful means of conquest must be on the lines of physiological resistance. The soil must be rendered sterile. A healthy condition of tissues and fluids best fulfils the indication, in that it is antagonistic to bacterial growth and activity.

Not much, we fear, is to be expected from vaccination experiments. Tuberculosis, unlike smallpox and its congeners, is not a disease of which one attack confers immunity from subsequent attacks. On the contrary, one who has already had the disease shows a special predilection to reinfection.

EMPLOYMENT FOR THE INSANE.

A visit to an asylum for the insane is for a normally minded person one of the most distressing things in the world. And this is so not because of the evidences of aberration of mind, but largely or entirely because of the mental, moral and physical wrong done the poor souls there incarcerated by their enforced, continuous, maddening idleness. Hour after hour, day after day, week after week, month after month, they have nothing to do but to eat their own hearts. As a little outlet for mere physical energy, often pathologically superabundant, they can only pace back and forth like caged animals, or sit and sway their bodies and pursue the phantoms of their morbid imaginations. It is a horrible sight, and it is a marvellous thing that any recover. The simplest promptings of pity would dictate giving these uselessly busy fingers something useful to do, and furnishing these active minds some other occupation than that of feeding upon themselves. Could anyone resist morbidity of mind, and even insanity, if compelled to sit thus brooding and inactive for

years? What a prophylaxis is work against mental disease! There can be no question that some insane could not or would not do any work, but it is still more indubitable that to the vast majority proper work would be an inexpressible blessing and powerful adjuvant in treatment. The system would have to be instituted with care, guarding against cruelty, improper tasks, etc.; but because life has always been synonymous with activity and interest, such a system must fall in with the order of Nature, and finally yield beneficent results.

As an instance of the success of such a movement may be cited the "Hospice St. Jean de Dieu," at Dinan, France, where a marked peculiarity of the treatment of the insane is their judicious employment. A correspondent of the New York *Post* says of his visit to this hospital:

"I was especially impressed with the contentment (one might easily use a stronger word) visible in the faces of the many patients whom I saw busy in the quarry, and the orchards, and the hay-fields. (The grounds of the asylum cover 126 acres, and are worked almost entirely by the patients under the direction of the Brothers.) 'Yes, they are almost happy,' the Prior said in answer to my exclamation of surprise. 'A great number are peasants who have been accustomed all their lives to hard work, and whose condition would be seriously aggravated by idleness. Their contentment is the result of life in the open air, and of occupation which distracts their troubled thoughts, but most of all it comes from the sense of *being trusted.*'"

At Gheel, in Belgium, similar methods of treating the insane have long been in use. Dr. Wm. J. Morton, after a visit to this colony, says:

"Gheel teaches us the possibilities that exist in the treatment of the insane. It shows us that they will work cheerfully if well managed, and that they may be treated, under proper precautions, with great liberty, and not abuse it. It teaches us, moreover, how wofully wide our advanced civilization is from the mark it might attain to in the treatment of insanity."

And there is another phase of the matter that should not be lost sight of. All problems, whether of the mind, the body, or of society, have a financial aspect, and in our modern life this is fast becoming more and more dominant. When we ponder upon the ominous fact that the number of the victims of mental diseases is increasing faster than the general population; when we think that already in the United States we have about 100,000 insane[1] that are supported by public charity, and that the financial burden, amounting to many millions of dollars annually, is levied upon the sane workman outside of the hospitals—when we reflect upon these things we then see that to the mental, moral, and therapeutic injury done the patient by corroding idleness there is added a financial wrong done the community by the same patent and potent evil. By allowing the patient to contribute to his own support a double good would result, instead, as from the present system, a double wrong.

[1] An increase of about 60 per cent. in ten years!

REVIEWS.

Fever: Its Pathology and Treatment by Antipyretics. Being an Essay which was Awarded the Boylston Prize of Harvard University, July, 1890. By Hobart Amory Hare, M.D., B.Sc. Pp. 162. Philadelphia and London: F. A. Davis, 1891.

The title originally adopted by Dr. Hare for this dissertation—*The Uses and Values of Antipyretics*—which we believe he was compelled to abandon in order to enter it for the Boylston Prize, far better describes its scope than that under which it is now published. It is, in reality, a description, from both the experimental and clinical standpoint, of the more modern antipyretics, based on laboratory and hospital investigations. The effects and utility of these antipyretics in the management of febrile and non-febrile ailments are detailed, and the published untoward results arising from their employment in various affections are cited and arranged in very convenient tabular form. The work, like all that proceeding from the fertile brain and pen of Dr. Hare, is well done. It furnishes a most excellent *résumé* of the physiological action and therapeutic uses of the drugs considered. We regret that it should be published with so misleading a title.

Lectures on Tumors, from a Clinical Standpoint. By John B. Hamilton, M.D., LL.D., Professor of Principles of Surgery and Clinical Surgery, Rush Medical College, Chicago, etc. For the Use of Students. ("Physicians' Leisure Library.") Detroit, Michigan: George S. Davis, 1891.

This little work is one of a class of books that a conscientious critic greatly dislikes to review. Every page contains so many errors, both of fact and of methods of expressing facts, that little remains for the critic but general condemnation—and general condemnation is pleasant neither to give nor to receive. This is especially true in the present instance, in which the author's name would presumably have been a guarantee of better literary work, and that of the publisher a guarantee of typographical products not positively abominable. As instances of the latter class we cite a few words: "discrasia;" "a sarcomata;" "psammona;" "myroma: synonym, cartilaginous tumor;" "pelvic hæmotoma do not differ;" "pudenta and pudental;" "parenchymata;" "dernier resort;" "tic douloreux;" "usualy."

Plain Talks on Medical Electricity and Batteries. By Horatio R. Bigelow, M.D. Pp. 85. Philadelphia: P. Blakiston, Son & Co., 1891.

Dr. Bigelow's *Plain Talks* consists of excerpts from the works of a number of recognized authorities on electricity. The author lays no claim to originality. The compilation as such is a good one, but the work suffers by contrast with the more original one of Adams. The therapeutic index, useful for ready reference, is the best feature of the book.

SOCIETY PROCEEDINGS.

SECOND CONGRESS OF TUBERCULOSIS,

Held in Paris from July 27 to August 2, 1891.

The second Congress for the study of Tuberculosis in man and animals was officially opened on Monday, July 27th, at the Medical School of Paris, under the presidency of Dr. Villemin, who was the first to demonstrate experimentally the contagious character of tuberculosis. Among the members present were Pasteur, Charcot, Cornil, Brouardel, Lannelongue, L. H. Petit, etc.; Jacobi and Page, from the United States; Watson, from England; Semmola, from Italy; Metschnikoff, from Russia; in fact, every European country was well represented. In his opening address, President Villemin presented an historical sketch of tuberculosis, both clinical and bacteriological, mentioning the different treatments proposed during the last few years, and concluded by saying that for many years to come we shall have to be satisfied with partial success.

Prof. Verneuil then read a paper on "Emigration, or Change of Place of Residence, in the Prophylaxis or Treatment of Tuberculosis." The paper was arranged in a series of paragraphs, which can be summarized as follows: 1st. Change of residence has a decided influence on the development, rapidity, and termination both of medical and of surgical tuberculosis. 2d. The change may be either from the city to the country or from the country to cities; the former exerts a favorable influence upon the course of tuberculous disease, while the latter favors the appearance and progress of tuberculosis. 3d. These two facts, well established by clinical observation, are of capital importance as to the prophylaxis and treatment of tuberculosis. Dr. Verneuil insisted that the patient be informed by the physician that by sacrificing himself and not going to the country he will rapidly reach the end of his disease, while an early change of residence may entirely eradicate the trouble. It is not absolutely necessary that a patient be sent to the country; should he live in a large city he may be sent to a smaller city, the location and sanitary condition of which are better than the large and crowded city. A stay in the country is most serviceable in many forms of local surgical tuberculosis, such as ulcers, fistulæ, articular diseases; also in case of latent tuberculosis or of recent operation. When a patient has been sent from the city to reside in the country, he ought not to be allowed to return to his former residence before the results of a careful physical examination indicate that the return can be made with impunity. Unfortunately, fixed rules cannot be laid down, yet a change of residence made in childhood or in adolescence ought to be prolonged until adult life has been reached; a patient ought not to be allowed to return unless his disease has at least been stationary for some time, or has preferably undergone decided improvement.

As is well known, tuberculosis is much more common in cities than in the country. It is also much more rapid and serious in cities, and certainly does not subside in as large a proportion of cases and as rapidly as in the country; we in the city constantly see mild forms of tuberculosis that have a tendency to perpetuate themselves and to reach an alarming intensity, while the contrary is observed in the country; again, serious tuberculosis is almost always fatal in a city, but, in the country, cures have been reported; the average life of city tuberculous patients is certainly much lower than that of country tuberculous patients; finally, Verneuil concluded his communication by emphasizing the great service country physicians can render by forbidding tuberculous patients to live in cities while they still present the slightest evidence of tuberculous disease.

Prof. Grancher and Dr. H. Martin next read a "Note on Anti-tuberculous Vaccination." They first passed in review the question of the duality of tubercle-bacilli, which has been a point of discussion for several years past; two kinds of tubercle bacilli are now cultivated: the human tubercle bacillus and the tubercle bacillus of birds. Koch admits that these two kinds of bacilli are different, but very slightly so; while MM. Straus and Gamaleia think that they are two absolutely different species; Cadiat, Gilbert and Roger believe in the unity of the bacilli. The experiments of Grancher and Martin have been made with both bacilli of birds and human bacilli; but the rabbit, which has been the animal experimented upon, is sensitive to both, and perhaps more so to that of birds than to that of man, so that, from a scientific point of view, the results as to immunity obtained against the most virulent of bird-tuberculosis by total or partial vaccination hold good for human tuberculosis. Grancher and Martin think that these bacilli are two varieties of one species. They are partial unicists.

The dualists base their opinion on the different aspects of the cultures; on the different pathogenic action of the two bacilli; on the immunity of the dog to the bird-bacillus and the immunity of the hen to the human bacillus.

As regards the cultures: Bird bacilli cultures, it is true, are often moist and soft and more or less wrinkled, while human bacilli cultures are dry and verrucous, but Grancher and Martin have often seen bird-bacilli cultures dry and verrucous and human bacilli cultivated on glycerin agar-agar soft and wrinkled; they have in their laboratory two fresh cultures of both bacilli which cannot be differentiated.

As regards the difference in the pathogenic action: With bird tubercle bacilli one can obtain any form of tuberculosis desired, from the infectious type of Yersin to the localized or benign tuberculosis of articulations.

As regards the immunity of the dog to bird-tuberculosis and of the hen to the human bacillus, this proposition falls to the ground, for hens have recently been infected with tubercle bacilli from human beings and dogs with bacilli from birds.

Grancher and Martin have conducted their experiments as follows: Rabbits weighing about two kilograms (4½ pounds) are for several weeks kept at the laboratory before being used. The same quantity of an opalescent culture in a little sterilized water is always used for inoculation; during the course of the experiment the vaccinated rabbits and the control-rabbits are given the same food, an important matter in such experiments. Each animal is weighed regularly every two or three days and the cage is kept clean and sterilized; even with these precautions small epidemics of enteritis and pneumonia are encountered, especially when animals are kept under observation for one or two years—and this long period is necessary if one wishes to learn the limits of the conferred immunity and not confuse partial with ultimate results; finally, the conclusive inoculation is made directly in the blood with the most virulent virus.

Grancher and Martin stated, as a curious and interesting fact, that as long ago as in 1888 they made experiments with a kind of "tuberculin" prepared by Martin, which somewhat resembled that of Koch; it was prepared as follows: A culture of tubercle bacilli in chicken broth with 6 per cent. of glycerin and 6 per cent. of sugar was filtered through clay. The filtered liquid is reduced to one-fourth of its volume by evaporation in a water-bath, and kept in a sterilizer at 120° C. (248° F.); the resulting liquid somewhat resembles "tuberculin" in its physical properties; it is also a glycerin extract of pure tuberculous cultures. All experiments made with the soluble products appeared to diminish rather than to increase the resistance of rabbits to the test-inoculation, so that these experimenters have given up further experiments with tuberculin to follow the antirabic inoculation method. Pasteur takes dried virulent cords; the authors have allowed their cultures to remain in tubes hermetically sealed, and in this manner the cultures become attenuated, and from month to month lose more and more of their virulence; these attenuations have been continued for a period of three years. A single injection of the virus, numbered ten, which is three years old, injected into the veins of a rabbit, is harmless. If the injection is several times repeated, the animal will die from tuberculosis.

The virus numbered one is from a fresh culture on glycerin agar, fifteen days old, which, injected into the veins of a rabbit weighing 2 kilograms, kills in from 15 to 20 days; sometimes the animal survives for 25 or 30 days, or it may die on the 11th or 12th. The lesions found are those described by Yersin.

The virus numbered two, three, and four, respectively injected, is fatal after a time that varies from 2 to 6 months; with that numbered five, six, and seven, death is not certain, but probable.

The following experiments were performed: On November 26, 1889, 9 rabbits were inoculated and 4 control rabbits were not. Each of the former received into the veins of the ear 1 c.c. of an opalescent dilution of tubercle bacilli, progressively more and more virulent. The 1st and 2d inoculations were made with a culture 33 months old; the 3d with a culture 22 months old, and so on, until all the rabbits were treated; the control-rabbits now, for the first time, received a culture of 4 months, corresponding to the virus numbered two. The four control-rabbits died, tuberculous, on the 23d, 27th, and 29th days after the test-inoculations, respectively, the last dying on the 154th day.

Of those vaccinated, one died, tuberculous, before the last inoculation was given; another died a few days after the last inoculation, while the others have lived a long time, some dying accidentally on July 19 and November 18, 1890, and January 29 and April 4, 1891. At the autopsy no trace of tuberculosis could be found, yet one rabbit was suffering from parenchymatous nephritis, while the last animal of this series still lived 21 months after the first vaccinal inoculation; he weighed 4.350 kilograms (9½ pounds), while his starting weight was 2.60 kilograms (4½ pounds).

It will be noticed that the control-animals died at variable periods—on the 23d, 27th, 29th, and 154th day of inoculation, yet they all received the same dose of the 4 months' old culture of the virus numbered two; this interesting fact is quite explicable, for if one had employed the pure fresh culture after a definite period, all these rabbits would have died almost on the same day; but the 4 months old culture had already been attenuated, and here comes into play the degree of resistance offered by each individual; and the idiosyncrasy of each animal has to be taken into account; one rabbit will resist for one month and another for six.

It will also be remarked that a rabbit died during vaccination and before the test-inoculation was made; this was due to the mode of inoculation employed; intravenous injection makes such complications possible, which are done away with, however, when the subcutaneous method is employed.

Another series of experiments by the subcutaneous method was begun on August 30, 1890. Each of 8 rabbits received 11 vaccinal inoculations until the virus numbered two was reached. Three that received, on December 8th, into the vein of the ear injections of human tuberculous virus, carefully admixed with the pulpified spleen of tuberculous guinea-pigs, remained in excellent health; they weighed 3.600 kgms., 3.500 kgms., and 3.800 kgms., each having gained 1000 grams. The control-animal died in the course of seven months, his body being stuffed with tubercles. This experiment proves that the bird-tubercletbacillus has the power of rendering the rabbit immune to the human bacillus.

In the first series of experiments, several of the rabbits died from intercurrent diseases, but no trace of tuberculous virus could be found, notwithstanding the enormous quantity of virus received.

One of the rabbits died from glomerulo-nephritis, which, according to Professor Grancher, is a very common affection in rabbits inoculated with tuberculous virus. Strange to say, the rabbits that die from that disease increase in weight after inoculation. In a series of 11 rabbits and 2 control-animals, the experiment being concluded on April 10th with an injection of the virus numbered one, the two control-animals died on the 3d and 10th of May respectively; while 8 of the others died from nephritis, without the slightest tuberculous lesion of either the kidney or any other organ; the three others died from pulmonary tuberculosis, but of a modified form; still all those rabbits lived for from 3 to 8 months, which certainly indicates that they had been favorably influenced by the virus.

Another interesting fact is that a vaccinated animal may

increase in weight from 2 kgms. to 3, 4, and 5 kgms., and die subsequently from a limited osseous or articular lesion; this enables Grancher and Martin to substantiate what they had already advanced, namely, that the longer the disease lasts the greater is its tendency to be benign and local.

Finally, the conclusions of this very interesting paper, the result of observations in eighty-two rabbits, is as follows:

Complete immunity to tuberculosis has not been conferred upon rabbits; the important fact has been determined that tuberculous virus has a vaccinal action against tuberculous virus itself.

Anti-tuberculous vaccination is imperfect, but does exist. Again, the tuberculous virus employed contains a vaccinal substance and a toxic one, the last being the cause of the nephritis developed, while the first confers a more or less prolonged immunity to infection. If the vaccinal virus have been varied, the results have varied, which is an indication of the efficacy of the virus employed.

The next communication made was by MM. ARLOING, RODET and COURMONT on, "Experimental Studies of the Properties Attributed to Koch's Tuberculin." These experimenters tested the three principal properties attributed to Koch's remedy—its curative value, its diagnostic value and its preventative property. They were unable to produce an acute intoxication, even by using large doses; on the contrary, frequently repeated small doses produced a sort of chronic intoxication.

A rise in the temperature is one of the most conspicuous symptoms; it is preceded, however, by a prodromic stage, which seems to indicate that this rise is not directly produced by tuberculin, but probably by a heat-producing substance, which gradually forms under the influence of tuberculin. As to its diagnostic value, experience has shown that it is not infallibly to be relied upon.

From a therapeutic point of view these authors have found Koch's remedy useless in the case of bird, bovine or human tuberculosis in animals. Finally, these experimenters attempted to verify the assertion of Koch, made at the International Medical Congress, that the guinea-pig was rendered immune to tuberculosis by treatment with tuberculin; they found, on the contrary, that in many cases the guinea-pigs were thus rendered much more susceptible to tuberculous lesions; in fact, that the lesions were much more confluent.

Finally, the day session was closed by a report of the librarian of the Faculty of Medicine of Paris, Dr. L. H. Petit, who is the General-Secretary of the Congress, and who gave a clear and interesting account of the work done and the results obtained by the last congress on tuberculous.

(*To be continued.*)

CORRESPONDENCE.

THE MEDICAL DEPARTMENT OF THE INTERNATIONAL ELECTRICAL EXHIBITION AT FRANKFORT-ON-THE-MAIN.

THE purpose of the International Electrical Exhibition at Frankfort-on-the-Main is to display all the latest advances and improvements in electrical science, and to stimulate to new efforts and further progress. The exhibition offers many points of interest, to medical nme in particular. In a hall built especially for medical and scientific purposes are to be seen the latest inventions in electro-diagnostic and electro-therapeutic appliances. It would be quite superfluous to go into the details of the exhibits, but it is worth while to take a cursory view of them.

The electromotor power of the various apparatuses is derived from many sources—from various kinds of galvanic batteries, from the currents produced by large dynamos, and from accumulators. Batteries of the latter kind are made of convenient size, and are easily transportable; they can be highly recommended for purposes of illumination, as they furnish a most constant light, and can at small outlay be introduced where no other arrangements for the production of electric light exist.

The contrivance of Dr. Bröse, of Berlin, first introduced last year, by which all medical instruments can be connected with the wires that conduct from the central station currents for illuminating or for mechanical power, is quite successful. The current enters the branch wire with a force of about 100 volts, and must, of course, be weakened for medical purposes. The weakening is accomplished by means of a rheostat that regulates the maximum current introduced into the circuit; by means of a second rheostat the current can be regulated to a nicety. In this manner a galvanic current of any intensity, from a fraction of one milliampère to several hundred milliampères, as may be needed for the purposes of electrolysis, can easily be obtained. The apparatus is perfect in action, and as it can be used without danger, there is no doubt that it has for medical purposes, a great future before it. The current is absolutely constant, and the disagreeable and inconvenient galvanic elements can now be dispensed with. The apparatus has also the great advantage that the cost is very small, and that it can be employed in any house in which electric lighting is in use.

The current from the central station may also be used for galvano-caustic purposes, and is most decidedly to be preferred to the current produced by elements.

Galvanic elements are exhibited in every conceivable form and in the highest degree of perfection, for the purposes of constant as well as inductive apparatus, electrolysis, galvano-caustic appliances, electric baths, and lighting.

The electromotors have been used in the medical section to provide the motive power for frictional machines, as well as for drilling-machines in the dentist's room.

The various lighting apparatuses, of which a great number is exhibited, claim particular attention. As especially worthy of notice may be mentioned the illuminating apparatus for investigating the cavities of the forehead and upper jaw, made in the smallest forms; it promises to be of great value in the diagnosis of tumors, as well as of accumulations of pathological collections in the cavities mentioned. Several dark-rooms have been prepared in order to test the apparatus.

It is needless to say that the latest improvements in galvanometers, rheostats, induction apparatus, etc., are to be seen.

As being particularly interesting, may be mentioned

the apparatus designed by Dr. Carl, a well-known oculist of this city, by means of which the refraction of the eye can be ascertained with great ease and in a short time. The instrument is so constructed that only single letters are seen. They appear in a vertical slit on a white disc, alternately in the upper and lower parts.

Quite apart from its great intellectual interest, the exhibition is worth a visit.

In the course of the summer, a congress of German physicians for nervous diseases will be held for the purpose of preparing the way for a purely scientific method of electro-therapeutic treatment.

NEW METHODIST HOSPITAL MEDICAL STAFF.

To the Editor of THE MEDICAL NEWS,

SIR: As many rumors have drifted to my ears concerning criticisms of the recent medical elections at the new Methodist Hospital, it seems but right to myself and to the hospital to make the following statement:

There were 30 candidates for the positions upon the medical staff, the schools of graduation being as follows: Woman's Medical College, 3; Jefferson Medical College, 3; University of Maryland, 2; University of Pennsylvania, 22.

Under the opinion given to the Board of Trustees by their solicitor, the will of Dr. Stewart, the founder of the hospital, required that no person should be elected upon the medical staff who did not have the title of A.B. from a college or university. As this title is one that is by almost universal custom only given after examination, it was not considered, by most of the trustees at least, that persons who had received the title from some small college by gift were within the limits contemplated by Dr. Stewart. The High School of this city has the legal right to give the title of A.B., but the solicitor did not consider that it could fairly be considered a college. Under this and other restrictions in the will of Dr. Stewart, not necessary here to detail, the trustees found that no candidates from the Woman's Medical College or the Jefferson Medical College were eligible, and that of the other candidates, only one coming from the University of Maryland and eleven from the University of Pennsylvania were within the terms of the will. Under these circumstances, they elected for physicians Drs. J. H. Lloyd, R. C. Norris, and F. A. Packard; for surgeons, John B. Roberts, H. R. Wharton, H. H. Kynett, and W. C. Hollopeter. One vacancy was left in the medical staff proper.

The above statements are based upon an analysis made by the Rev. Dr. McConnell, Secretary of the Board of Trustees, from information furnished in response to inquiries by the candidates themselves, and is, I think, entirely accurate, excepting in that Dr. John B. Roberts graduated at the Jefferson College before he took his degree at the University of Pennsylvania.

Yours truly,
H. C. WOOD, M.D.

1925 CHESTNUT ST, PHILADELPHIA, PA.,
July 18, 1891.

Dr. Victor C. Vaughan has been elected dean of the faculty of the medical department of the University of Michigan.

NEWS ITEMS.

Joseph Eastman, M.D., LL.D.—The degree of doctor of laws has been conferred by the Wabash College, of Crawfordsville, Ind., upon Dr. Joseph Eastman, president of the faculty and professor of the diseases of women and abdominal surgery in the Central College of Physicians and Surgeons, of Indianapolis.

Dr. Henry V. Wilson, recently in charge of the United States Fish Station at Wood's Holl, Massachusetts, has been elected professor of biology in the University of North Carolina. He will at the same time be Assistant Shell-fish Commissioner for the State, and scientific expert to the Commission.

Artificial Feeding of Infants.—The Société Médicale des Hôpitaux offers a prize of 1200 francs ($240) for the best essay upon the Artificial Feeding of Infants. Papers in competition must be in the hands of the secretary of the Society before the first of July, 1892.

Dr. H. M. Whelpley, professor of microscopy in the St. Louis College of Pharmacy, has been elected professor of physiology and histology, director of the histological laboratory and secretary of the Missouri Medical College.

The Alvarenga Prize for 1891, of the College of Physicians of Philadelphia, has been awarded to Dr. L. Duncan Bulkley, of New York, for his essay on Syphilis Insontium.

Nathan Bozeman, M.D., LL.D.—At its recent commencement the University of Alabama conferred the degree of doctor of laws upon Dr. Nathan Bozeman.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 4 TO AUGUST 10, 1891.

GIRARD, ALFRED C., *Major and Surgeon.*—Relieved from duty at Fort Niagara, N. Y., and ordered to Fort Sheridan, Ill., for duty.

SKINNER, JOHN O., *Captain and Assistant Surgeon.*—Assigned to duty at Fort Clark, Texas.

BRADLEY, ALFRED E., *First Lieutenant and Assistant Surgeon.*—Granted leave of absence for thirty days.

KNEEDLER, WILLIAM L., *Assistant Surgeon.*—The leave of absence granted is extended one month.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 8, 1891.

MARMION, R. A., *Surgeon.*—Detached from the Navy Yard, Norfolk, and ordered to the Navy Yard, Boston.

WINSLOW, G. F., *Surgeon.*—Detached from Marine Rendezvous, Boston, and ordered to the Navy Yard, Norfolk, Va.

PARKER, J. B., *Surgeon.*—Detached from the Navy Yard, Boston, and placed on waiting orders.

BRAITHWAITE, F. G., *Assistant Surgeon.*—Ordered to the Receiving-ship "Wabash," at the Navy Yard, Boston.

URIE, J. B., *Assistant Surgeon.*—Detached from the Receiving-ship "Wabash," and ordered to the Marine Rendezvous, Boston.

CORDEIRO, F. J. B., *Passed Assistant Surgeon.*—Detached from the Naval Hospital, Chelsea, Mass., and granted two months' leave of absence.

PICKERELL, G. MCC., *Passed Assistant Surgeon.*—Detached from Hospital, New York, and ordered to Hospital, Chelsea.

HEPATIC ABSCESS AND THE AMŒBA COLI.[1]

BY JOSEPH EICHBERG, M.D.,
PHYSICIAN TO THE CINCINNATI HOSPITAL.

OUR knowledge of the direct, essential causes of disease is all too limited. The past few years have witnessed some important additions to this obscure department of medicine, and more promise to follow. We are indebted to the microscope for many of the more recent acquisitions in this field, of which the case I herewith report is an illustration. The case is of interest, because the results of investigations upon the relation of the amœba coli to abscess of the liver are not as yet sufficiently appreciated by the body of the profession; and all additional testimony can but serve the purpose of carrying conviction more deeply to doubting minds. The patient entered my service at the Cincinnati Hospital, and I am indebted for the following complete notes to Drs. Morris and Landis, internes of the medical and surgical wards respectively:

H. B., thirty-five years old, colored, a laborer, of good physique, married; was admitted to the medical ward of the Cincinnati Hospital December 13, 1890. His father is said to have died of phthisis; a brother of pneumonia. The patient had had pertussis, measles, rheumatism, malaria, orchitis and chancre.

In June the patient was suddenly seized with pain at the base of the right lung. The appetite was impaired; he had night-sweats; he was extremely debilitated. In a short time he began to improve, but was not able to resume work, and steadily lost strength and flesh. There was also cough, that steadily grew worse, with free, bloody, muco-purulent expectoration. Two days before admission, shortness of breath became decided, cough became much worse, with pain in the right side. The man had been confined to bed for two months.

On admission to the hospital sleep was disturbed, and there was still some pain in the right side. The cough was frequent, the expectoration muco-purulent and bloody. The appetite was poor; the bowels regular. The pulse was 108; the temperature 99°. There was edema of the feet and lower extremities. Micturition was normal. The urine was of amber color, of acid reaction, of a specific gravity of 1030, and contained neither albumin nor sugar. The patient was very well developed and well nourished. The tongue was pale, the throat normal. The chest was well formed; the respiratory movements were limited upon the right side. Over the liver the intercostal spaces were obliterated, with bulging of the chest; the respiratory movements were accelerated (30 per minute); expiration was prolonged; there was some supra-clavicular retraction; there was percussion dulness over the whole right lung anteriorly, and slight dulness posteriorly, increasing from above downward; at the apex the resonance was fairly good; at the base there was flatness. There was dulness on percussion over the lower lobe of the left lung, anteriorly and posteriorly. On auscultation of the right lung, tubular breathing, with moist râles, was heard in the upper lobe, with gradual diminution of the sounds downward, until at the base the sounds were distant and blowing in character. In the left lung, moist râles and tubular breathing were heard in the lower lobe; sonorous râles in the upper lobe. Vocal fremitus was markedly diminished over the lower lobe of the right lung, and increased over the remaining portion of the right lung and over the left lung. The apex-beat was seen in its normal position; no abnormality of the heart was detected. The abdomen was somewhat distended; the increase in size had been noticed for a few days. No abnormality in the abdominal viscera was detected; a moderate collection of ascitic fluid was present. The feet and legs were edematous, pitting on pressure. The swelling had appeared at intervals during the previous two months. The existing swelling had been present for a week. The patient had external hemorrhoids.

A diagnosis of phthisis, lobular pneumonia and pleurisy, with serous or purulent effusion, was made.

Despite energetic treatment with whiskey, ammonium carbonate, morphine, phenacetin, iodoform suppositories, Hope's mixture, paregoric and aspiration, the patient failed to improve; cough and hemoptysis persisted; inability to sleep was troublesome, and diarrhea set in.

On December 20th Dr. P. S. Conner saw the patient in consultation, and consented to perform paracentesis, and to have the patient transferred to his service. With his permission I append the remaining notes, made during the patient's stay in the surgical wards: An incision two inches long was made in and parallel with the seventh intercostal space in the axillary line. A quantity of bloody fluid was evacuated, apparently containing pus, but unlike the material evacuated in the orginal aspiration. On passing the finger into the chest extensive and firm adhesions were found, apparently separating this fluid from more above. An incision, one inch in length, was accordingly made in the sixth intercostal space, and a large quantity of thick, greenish pus and bloody

[1] Read before the Cincinnati Medical Society, February 3, 1891.

fluid of disagreeable odor was evacuated. A large drainage-tube was introduced into the upper incision, the lower was drained with an iodoform-gauze stuffing, and dressed with bichloride gauze and cotton. The patient felt greatly relieved by the operation, and had much less difficulty in breathing. Cough and diarrhea, however, continued.

On December 30th the appearance of the patient was bad; emaciation was marked; a peculiar odor emanated from the body, and could be noticed at a distance of ten or twelve feet. On the following day the patient became much worse, sank rapidly, and died.

Temperature, pulse and respiration pursued the following course:

December 14. A.M., temperature, 99.6°; pulse, 120. P.M., temperature, 103.4°; pulse, 132; respiration, 36.

15th. A.M., temperature, 100°; pulse, 120; respiration, 36. P.M., temperature, 100.8°; pulse, 120; respiration, 36.

16th. A.M., temperature, 99.4°; pulse, 120; respiration, 30. P.M., temperature, 99; pulse, 126; respiration, 30.

17th. A.M., temperature, 100.6°; pulse, 120. P.M., temperature, 103; pulse, 126.

18th. A.M., temperature, 101.2°; pulse, 120. P.M., temperature, 102.8°; pulse, 126.

19th. A.M., temperature, 100.4°; pulse, 120. P.M., temperature, 100.6°; pulse, 120.

20th. A.M., temperature, 100°; pulse, 120. P.M., temperature, 99.4°; pulse, 120.

21st. A.M., temperature, 98.8°; pulse, 120; respiration, 30. P.M., temperature, 100.8°; pulse, 120; respiration, 32.

22d. A.M., temperature, 99.8°; pulse, 122; respiration, 28. P.M., temperature, 101.2°; pulse, 128; respiration, 32.

30th. P.M., temperature, 98.4°; pulse, 116.

The post-mortem examination was made twelve hours after death by Dr. F. Kebler, pathologist: Man, apparently thirty years of age. Post-mortem rigidity well marked. On right side of chest, in axillary line in fifth intercostal space is an incised wound several inches long, from which protrudes a drainage-tube. The right pleural cavity was found to contain about one pint of blood-stained pus. Numerous recent adhesions bound the lung to the chest-wall and to the diaphragm. On the left side were some old pleural adhesions. In the lower lobe of the right lung was found a cavity large enough to admit the closed fist. By a perforation of the diaphragm the excavation communicated with a large abscess-cavity in the liver. Both contained a considerable quantity of blood-stained pus. In the right lobe of the liver posteriorly was found a large-sized pus-cavity, communicating with the pleural cavity by means of the perforation in the diaphragm noted. Surrounding the main abscess-cavity were numerous smaller ones, varying in size from a small nut to a pigeon's egg. The pus in all these cavities was more or less blood-stained. Kidneys, stomach, spleen and small intestines were all normal. The large intestines contained a small number of old dysenteric ulcers.

Until the moment of aspiration I was under the impression that we were dealing with a case of phthisis that had given rise to a sacculated exudation in the right pleural cavity, the boundaries of the fluid-accumulation being clearly traceable upon physical examination by the dulness, absence of breath-sounds and diminished vocal resonance. The muco-purulent character of the expectoration, tinged, as it was, with blood, seemed confirmatory of such a diagnosis; and I was prepared, from the almost rusty character of some of the sputa that I had seen, to find an acute lobar pneumonia, developed in the course of what I firmly believed to have been an advancing phthisical destruction of the lung. The fever, the night-sweats, the loss of strength and flesh, accorded well with such an opinion; nor was there aught in the physical signs to direct attention to the liver as in any way involved in the difficulty.

Posteriorly, the pulmonary resonance over the right side was pretty clear, and extended downward almost to the usual level. Anteriorly, the lower border of the liver-dulness coincided with the lower costal margin; the upper border in the anterior axillary line was in the sixth intercostal space; anteriorly, the hepatic dulness passed insensibly into that due to the exudation. Moreover, aside from pain in the lower portion of the chest, early in the course of his illness, nothing in the patient's history suggested hepatic trouble. The patient denied having had anything like a dysenteric attack, but I am now inclined to believe that much obscurity in his history was due to ignorance or to mental hebetude.

The case was aspirated in the presence of the class of students at the hospital, who had been informed of the possibly purulent character of the fluid. As soon as the chamber of the aspirator began to fill, all doubt as to the nature of the case was removed. The thick, almost gelatinous, greenish-red exudation, with occasional streaks of creamy pus, alternating with a fluid of the color of anchovy sauce, could come from only one organ in the body. Clinicians and pathologists are familiar with the characteristics of this pus, which, when allowed to stand for a short time, becomes more viscid, presents a sort of glossy, shining surface, and at times almost seems to undergo a sort of coagulation, solidifying into a semi-solid mass; it rarely shows any trace of bile-coloring matter or of bile-salts. It is the fluid found originally only in hepatic abscess, so that its presence in other localities is in itself proof-positive not only of abscess of the liver, but of communication between the abscess and the accidental cavity in which this pus may be encountered.

There was no hesitation, therefore, in declaring that the case was not one of phthisis, but of hepatic abscess, perforating the diaphragm, with subsequent

perforation of the lung. Hence the peculiar character of the expectoration, the sweats, the fever and the prostration; hence the early pain in the right side and the dyspnea; hence, too, the circumscribed sacculated cavity in the pleura, with dulness on percussion, passing insensibly into the liver-dulness. The abscess evidently was situated in the right lobe, near the upper convexity, so that it had found less resistance in advancing upward than in a gradual invasion of the liver substance. The absence of any enlargement of the liver sustained this view. It is interesting to note the change in the sputum from purulent to clear white, frothy mucus, immediately after the aspiration; only again to become purulent after a brief interval. The pus-cavity filled rapidly, and surgical intervention was distinctly indicated.

As shown by the autopsy, the operation came too late to be of service, since multiple abscesses had formed in the liver, possibly by infection from the original source, more probably by local infection from the large primary abscess. The arrangement of the secondary or smaller abscesses in a somewhat concentric manner around the larger cavity, their tolerably uniform size, and the appearance of smaller, almost microscopic, pus-collections on their confines, would argue rather for a local than a distant source of infection. This should obviously incite to early evacuation, with free drainage, whenever abscess of the liver is recognized; nor should incision be even tentatively delayed by aspiration.

The conviction that the case was one of phthisis, of rather unusual distribution, seemingly affecting the bases of both lungs, caused us to neglect the microscopical examination of the sputum; so certain were we, that the usual examination for bacilli tuberculosis was not even asked for. However, upon recognizing the true character of the case, examination of the stools and pus was repeatedly made, with the uniform result of showing us, present in large numbers, the amœba coli, the organisms the association of which with tropical dysentery and hepatic abscess is, by some clinicians, now considered causal.

My attention had been particularly directed to the article upon the amœba coli in the *Bulletin of the Johns Hopkins University*, from the able pen of Professor Osler. Sketching with characteristic ability and clearness the rather meager literature of the subject, the article embodies the full report of a case of hepatic abscess, characterized by the presence of amœba coli in the stools and in the pus. A subsequent communication in the same journal, by Professor Welch, pays special attention to the appearance of these organisms, which Leuckart classified as belonging to the rhizopods. A third article, also in the *Bulletin*, by Dr. Simon, reports a case in which the diagnosis of hepatic abscess perforating the lung was correctly made from the recognition of the amœba in the sputum.

While highly flattering to the zeal of the medical staff of the Johns Hopkins Hospital, it is singular that this should embrace, so far as known to me, all of the American medical literature bearing upon the point in question.

There is little, if anything, to add to the lucid and succinct description of Professor Osler. The specimens of amœba observed by myself and by others of the medical staff of the Cincinnati Hospital conformed accurately to the account he has given, part of which I take the liberty of reproducing here. Some of the amœbæ were considerably larger in size than those figured by him, though the average would not exceed his estimate. The greatest variation was observed in the rate of movement, some travelling across the field with almost lightning-like rapidity, others being very sluggish in sending out the knob-like processes that seemed to precede each change of place. The following is the reference alluded to:[1]

"*Description of the Amœbæ.*—(a) From the liver: The size ranged from 10μ to 20μ, which appears to be somewhat greater than that indicated by Kartulis. When at rest the outline was usually circular, occasionally ovoid; but when in motion they presented, as shown in the figures, the extremely irregular contour of moving amœboid bodies. The protoplasm could be distinctly differentiated into a translucent homogeneous ectosarc, or motile portion, and a granular endosarc containing the nucleus, vacuoles and granules. The hyaline ectosarc was, as a rule, very distinct, and in many examples the granular protoplasm of the interior was surrounded by it as a distinct rim. Occasionally a form was seen in which this portion was much less developed, and the greater part of the organism seemed composed of granular substance. Within the endosarc the vacuoles constituted the most striking feature. Sometimes the interior substance appeared to be made up of a series of closely set, clear vesicles of pretty uniform size. As a rule, one or two larger vacuoles were present, the edges of which were not infrequently surrounded by fine dark granules. I never saw a true contractile vesicle which displayed rhythmical pulsations, but the larger vacuoles underwent at times changes in size. The nucleus was plain enough in some examples; in others very difficult or impossible to detect. It was usually pale, ovoid or rounded in outline, and with a very delicate contour. No distinct nucleus was seen, though there were sometimes coarser granules which possibly represented it.

[1] The Johns Hopkins Hospital Bulletin, vol. i., No. 5.

"When once recognized there was not the slightest difficulty in distinguishing these bodies, even when at rest, from the pus-elements, not only by their size but by the entirely different appearance of the protoplasm.

"The movements, however, constitute their most interesting and distinctive features. From any portion of the surface a rounded hemispherical knob would project, and with a somewhat rapid movement the process extended, and the granules in the interior streamed toward it. As in the pond-amœbæ, the clear ectosarc seemed to initiate and play the important part in the movements. Though sometimes slow, many examples were found in which the alterations in contour and the change in locality were quite as striking as in the large, active forms of pond-amœbæ. The processes were always rounded, never angular or linear, as in white blood-corpuscles. Motile forms were found each day in the pus during life. They seemed at times more active apparently than at others, and the movements went on at the average laboratory temperature, but seemed increased by heat. They continued active for hours at a time. Twice the movements were observed to continue in the same organism for more than ten hours."

Beside personal observation, I have the following reports, kindly submitted by Dr. J. C. Oliver and Dr. C. S. Evans, curators of the pathological department:

December 17, 1890.—A specimen of pus, obtained by aspiration, was examined for liver-cells; large multinuclear cells were found containing some pigment. Upon the same day, chemical examination of the pus showed no trace of bile-pigment.

19th.—A stool of the patient was examined for amœba coli, which were found in moderate number and in active motion.

20th (date of operation).—Pus obtained from the chest-cavity was found to contain amœbæ in large numbers. The first field showed eight of these organisms. Elastic fibers of the lung were present in considerable quantity.

27th.—Pus from the wound showed amœbæ in considerable number, actively moving, and some elastic lung-fiber.

31st.—Pus from the wound contained active amœbæ, also lung-fiber and biliary coloring matter.

January 1, 1891.—Post-mortem specimens of pus from multiple abscesses showed amœbæ to be uniformly present. Upon staining, *no bacteria* were found.

Inoculation-experiments with sterilized agar were made by Dr. Evans. An attempt was made to cultivate the amœba in sterilized meat-broth. The experiment was also made with the hanging-drop; but these attempts proved unsuccessful, not yielding any growth of the amœba. As suggested by Dr. Evans, it is possible that future efforts in this direction would be more fruitful if sterilized gutter or sewer, or stagnant water be employed as culture media.

We have, then, a case of hepatic abscess, connected with dysentery, and amœbæ constantly present in the fecal discharges and in pus from the liver. Is the amœba the cause of both? More extensive clinical experience can alone determine this point with precision; what evidence we have is wholly confirmatory; and it remains to be seen if cases of dysentery ever occur independently of all association with the amœba. The observations of Professor Koch and his cholera commission, as summarized by Kartulis, show the constant association of the amœba with tropical dysentery, and its presence in the wall of the intestinal ulcers, as well as in the contents of the gut.

Whether or not tropical dysentery differs in this respect from the sporadic variety occurring in temperate climates remains to be seen. In our case there was no history of residence in warm latitudes, although the patient's statements were not reliable. Accepting for the moment the dependence of dysentery upon the amœba coli, it is easy to understand how, by virtue of its great mobility, this organism should be enabled to penetrate the delicate capillary wall, or to gain entrance into the circulation through vessels opened by the ulcerative process in the intestine. Once in the circulation, its transmission to the liver through the portal circuit follows almost of necessity. Its arrest in the substance of the gland ensues, partly by reason of its own considerable size, as compared with the caliber of the vessels, partly because of the great complexity of the capillary network that would render futile a momentary elongation, made to conform to the outline of a single loop. Retained thus in the liver tissues it constitutes an irritant sufficiently intense to produce a low grade of suppuration, with more or less severe constitutional symptoms of sepsis. Judging from the number found in the pus, the multiplication of the amœbæ in the liver tissues must be comparatively slow. Secondary infection from the original abscess takes place by penetration of the pyogenic walls in consequence of the amœboid movements, and the arrest of stray amœbæ in the immediate vicinity.

The causal relation of the amœba to dysentery would also serve to explain some clinical facts in the history of that disease.[1] The first of these is the prevalence of dysentery in warm latitudes, and during the hot season of the year in temperate climates. The factor of temperature has the greatest possible bearing, as we know, upon the multiplication of all low organisms, whether animal or vegetable. (The warming of the slide bearing the

[1] See also Stengel, "Acute Dysentery and the Amœba Coli." THE MEDICAL NEWS, Nov. 15, 1890.—ED. NEWS.

amœbæ was always attended with greater activity of movement.)

Whatever the native culture-ground of the amœba (and the most natural inference would point to some water contaminated by an abundance of organic material), it is evident that high temperature, by increasing the number of amœbæ, would by so much favor their entrance into the body, and thus increase the morbidity from this cause. A second clinical fact, explicable upon the same hypothesis, is the undoubted curative value of simple ice-water injections, or of cold injections of boric fluid. In the former instance we are dealing solely with the manifest influence of temperature. As warmth favors a multiplication of organisms of a low order, cold either destroys their vitality entirely or suspends it sufficiently to enable the bowel to throw off, with the enema, the organisms, the presence of which is so deleterious. Were the enema of service merely by its cleansing effect, there would seem to be an advantage in the use of warm rather than cold fluids; yet clinical experience must assign the greater value to water of almost icy temperature. The addition of boric acid, as well as of other weak antiseptic solutions, would increase the efficacy by supplementing the destructive power of low temperature.

The evidence of causal connection of the amœba coli with dysentery and with hepatic abscess of dysenteric origin, thus far presented in medical literature, is not sufficient for definite statements; it must be considered as strongly suggestive rather than as conclusive; and it is with the view of stimulating further research upon a subject so interesting that I have ventured to present this history and these comments.

P. S.—An interesting point has been brought out since the foregoing was written. A patient, supposed to be suffering from some hepatic disorder, was admitted to the medical service of the hospital. Physical examination showed the presence of an abscess below the costal margin. Some pus was withdrawn by aspiration. No amœbæ were found. Subsequently paracentesis was performed, and it was seen that the abscess was sub-peritoneal, not connected with the liver or any abdominal viscus. In two cases of hepatic abscess, not occurring in my service, the amœba coli has been observed in the discharges from the abscess-cavity.

COMPARATIVE DATA IN THE TREATMENT OF UTERINE TUMORS.

By MARIE B. WERNER, M.D.,
of Philadelphia.

The safest method of treating uterine tumors has of late been a question that has aroused the most earnest debates, especially between surgeons and electricians. Those who have given the subject careful attention will have a little patience with me if I presume to add to the conclusions of others my own, based as they are on more than five years of careful study of two methods that are stern antagonists in the field.

Electricity has claimed the attention of many, and now, after some years of earnest trial, one can decide as to either its value or harm to the patient. Many so-called cures have been ascribed to its use, but from personal experience I feel sure that some important factors were lost sight of when such assertions were made. Patients having untold confidence in their physicians are often more than willing to keep pace with the desire to feel benefited, and should the doctor also be anxious to place faith in the method, reasoning from cause to effect will often be lost sight of on the pinnacle of faith.

There are certain points to be considered in the treatment of uterine tumors by electricity. The most important is *correct diagnosis*. In carefully reading Keith's report of 106 cases treated by electricity, one is impressed with the fact that cases of subinvolution, metritis and pelvic inflammation are classed alike under the head of uterine tumors.

Changes in the tumor are frequently encountered that must be considered—I allude to the suppurative, cystic, edematous and sarcomatous varieties; adding to this the fact that the appendages are more often diseased than not, it certainly becomes a matter of the most delicate diagnostic skill to make it safe for the patient to undergo treatment by electricity. Abdominal surgeons, no matter how experienced, often hesitate to name a painful mass or tumor before seeing it.

That the general health is sometimes improved after treatment with electricity has been demonstrated by the statistics of some of those who have made a careful study of the utility of this agent. Thus, Dr. John Homans,[1] of Boston, reports that of 35 cases treated by electricity, the general health was improved in 15, was made worse in 2, was improved and afterward made worse in 2, was unaltered in 11, and 5 were not heard from. Among those that were made worse he must include one case of death reported.

When we consider that the careful physician will attend to the general health of his patient, in conjunction with electrical treatment, we can readily understand the improvement, as well as that often proper hygienic care might have achieved it unaided. In referring again to Dr. Homan's conclusions, we find that profuse hemorrhage was diminished to within normal or bearable limits in 9, increased in 6, and unchanged in 9. The meno-

[1] Boston Medical and Surgical Journal, March 12 and 19, 1891.

pause occurred in a few cases after treatment was begun. If it is admitted that hemorrhage is checked by the application of the positive pole, and that the hemostatic effects are due to a cauterant action, many doubts and fears arise as to the ultimate results for the patient, for cicatricial tissue belongs, as we all know, to the lowly organized structures.

Dr. Franklin Townsend[1] reports 4 cases of uterine fibroids in his series of 17 cases treated by electricity. Such was his experience that he was satisfied to resume his surgical work, feeling that he could thereby do greater justice to his patients.

Those advising electrical treatment consider that a patient placing herself under the surgeon's care is passing through an operative shadow of death, is mutilated, and may look forward to a possible hernial weakness. If one studies some of the cases reported by the various advocates of electricity—for instance those contained in Keith's report of 106 cases of uterine tumors treated by electrity, Cases IV. and VIII. show at once that the patients not only passed through the shadow, but actually succumbed. Many others suffered from attacks of peritonitis; and all so-called cures seem doubtful to the careful student, since the presence of the tumor and a fluctuating condition of health makes one think that the sword of Damocles is still hanging over their heads.

Rutherfoord's[2] case shows how the patient was passing beneath the shadow of death for upward of five months. Here suppuration of the tumor and subsequent septic poisoning undoubtedly caused the train of symptoms that followed three intra-uterine treatments with the positive pole. In a recent discussion of Dr. John Homans' paper, Dr. J. R. Chadwick[3] gives an account of 11 cases treated by him with electricity for six months. In no case did the fibroids diminish in size during or subsequent to the treatment; in 3 cases metro-peritonitis was excited; one of these ended fatally on the sixth day; in one case general septicæmia set in a day after the sixth treatment, with a fatal termination from pulmonary embolism twenty-six days later. These results were the occasion of his abandonment of the use of electricity in gynecological practice.

Dr. Anna M. Fullerton[4] reports 9 consecutive cases of abdominal section, in which the harmful effects of previous electrical applications in cases of salpingitis and allied conditions were plainly demonstrated. Adding to this the fact that in cases of uterine tumors most of the appendages are either primarily or secondarily diseased, the danger of electrical treatment becomes at once apparent; it is certainly often one of the causes of localized peritonitis. Apostoli's directions prove that he has had reason to recognize this danger, for he says: "Only apply a dose that the uterus can bear. Never be rough or take the patient by surprise. Reach the maximum dose gradually and diminish it in the same manner." He makes another important statement: "Ovarian or tubal intolerance depending upon diseased appendages will demand an increased precaution, and forbid all applications of high intensity." Adding these cautions to the experience of the abdominal surgeon should be sufficient to cause a halt in the application of electricity in gynecology, and one should ponder well on the question of mutilation. In connection with this subject, I will briefly cite a case from my practice:

In March, 1886, I was consulted by a patient for painful, irregular, scanty menstruation. She was married, had never conceived, and was anxious to have children. Examination revealed two fibrous masses in the posterior wall of the uterus. There was a history of gonorrhœal infection. I used the continued current (negative pole). For five weeks the patient appeared to do well, and we were both encouraged; after that, however, she developed chronic peritonitis which finally became septic.

This was verified by a subsequent section, performed as a last resort to save life, in which Dr. Joseph Price assisted me.

This was sufficient to make me fully realize the dangers of electrolysis. I had seen Dr. Apostoli use it, and had followed his directions closely. To my mind there is less mutilation in removing diseased organs than in subjecting the patient to the dangers of sepsis. Again, when multiple fibroids and pregnancy coexist, the risk for the patient is increased, since it may become necessary to perform a Porro-Cæsarean to effect delivery.

Ventral herniæ are extremely rare when the necessary care is given to include enough fascia and muscle in the sutures, and the wound is accurately closed, with attention to sufficient rest in bed after operation, and the use of abdominal support.

Having considered the electrical question, we will turn to the surgical. There are two principal methods that have been more or less successful in the hands of our surgeons—removal of the appendages and hysterectomy. Myomectomy still presents many obstacles to the permanent recovery of the patient, since as long as some uterine tissue remains the enucleation of one or more tumors does not preclude the possibility of growth of others. Another important point for consideration is the condition of the appendages. This point can best be illustrated by the conditions found in a patient upon whom I had the privilege of seeing Dr. Joseph Price

operate. A multinodular fibro-myoma had become pedunculated; myomectomy would have been an easy matter, but the entire uterus and appendages having been removed, a subsequent examination of the specimen showed three small fibroids in the uterine walls, while the appendages had been bound down by dense adhesions and were diseased, amply proving that the patient's condition would doubtless have been made worse if myomectomy had been performed, since the source of greatest pain, adherent and inflamed appendages, would have been left, as well as the possibility of subsequent development of the three remaining nodules.

Leopold[1] makes a note of five cases in which subsequently to operation there was a development of other growths—in one case after removal of the appendages, and in four after enucleation—necessitating secondary operation. One of these cases ended fatally after hysterectomy—not, however, before having had a submucous growth removed after the myomectomy. These cases certainly go far to prove that myomectomy is not so safe as to ultimate results as is removal of the appendages or hysterectomy.

In which cases shall the one or the other be given the preference? Lawson Tait, with his vast experience, has given us his conclusions. These hold good for most cases. His investigations have led him to believe that the multinodular myoma is essentially a disease of menstruation; hence his advice is to remove the appendages in such cases, if possible. If this is done, and the patient has not yet reached the age of forty, the tumors generally disappear entirely. The edematous myoma, however, seems unaffected by the menopause, Tait having watched the progressive growth of one after the menopause until the patient was sixty-three years old, when he successfully removed it by hysterectomy. It is interesting to note further that Mr. Tait has performed hysterectomy for edematous myomata in the case of patients between the years of eighteen and thirty-one, feeling certain that removal of the appendages may arrest menstruation, but not the growth of the tumors.

The youngest patient in the case of whom he performed hysterectomy for multinodular myoma was thirty-seven years old, and the oldest fifty-two. This seems in a great measure to verify his statements as quoted.

In the early stages of myomatous growths, menorrhagia is one of the most troublesome symptoms. When there is pressure upon the bladder or pelvic structures, or if the appendages are inflamed or diseased, pain becomes an additional trial to the patient. Dr. Joseph Price, whose large experience enables him to make an estimate of these complications, states that the appendages are diseased in 95 per cent. of cases.

To sum up: The most rational treatment, based on scientific research, is to remove the appendages when the symptoms produced by the growth become unbearable to the patient, or if there is reason to suppose that the appendages are diseased from any cause. In the case of the multinodular myoma, this promises a cure, provided the operator is careful to tie close to the cornua of the uterus and to remove all ovarian stroma, together with all sources of infection or irritation, and has given careful attention to the minutest details of the toilet of the peritoneum, thus reducing possible secondary complications to a minimum.

There is, however, one other point to be considered, and, in order to illustrate it, I will briefly cite one of my own cases:

In October, 1889, I removed adherent and diseased appendages from an extremely anemic patient with a multinodular myoma. The usual metrorrhagia followed forty-eight hours after the operation, and lasted five days. Four weeks later the flow again came on, and in spite of ergot and hot douches continued fourteen days. Six weeks after the operation I dilated the uterus, and found a submucous growth the size of a hen's egg, removed it, and the hemorrhage ceased. In the following July (eight months later) another hemorrhage, dependent upon a second submucous growth, as large as a pigeon's egg, was checked by removal of the tumor. The patient has since had no return of the hemorrhage, and enjoys good health. The point I desire to make here is, that the patient was subjected to less risk by the use of the dilator and écraseur after the removal of the diseased appendages than had this method of procedure been the first step in her treatment. Dr. Bantock supports this view in an argument reported in the *Proceedings of the British Gynecological Society*, October, 1888.

Tait condemns any kind of uterine dilatation or medication when the appendages are inflamed or adherent. Leopold, on the other hand, advises exploration of the uterine cavity to determine the possible presence of submucous growths *before* removal of the appendages. The possible dangers in following this advice are clear to those that have witnessed attacks of pelvic inflammation follow intra-uterine manipulations, when there was reason to suppose the appendages were diseased.

In looking over the statistics upon the removal of uterine appendages by skilled operators, we find much to encourage us.

In his first series of 1000 sections, Tait[1] records

[1] Archiv für Gynäkologie, Band xxxviii. Heft 1.

[1] "Tait's First Thousand," British Medical Journal, 1885. "Tait's Second Thousand," British Medical Journal, November, 1888.

99 cases of removal of the uterine appendages, with 7 deaths, or a mortality of 7 per cent.; this is improved in the report of his second 1000—148 cases, with 3 deaths, or a percentage of 2.03.

Leopold[1] has collected the cases of ten operators (all German except Tait), giving a summary of 744 cases, with 60 deaths, or a mortality of 8 per cent. Leopold has credited Tait with 393 cases, while he has actually operated in but 247; deducting these, it leaves a mortality of 11.4 per cent. for the German operators.

The fact that removal of the uterine appendages does not always arrest the growth of the tumor, or that at other times hemorrhage remains a troublesome symptom, has been explained, and shows that accurate diagnosis at skilled hands, combined with good judgment, will reduce the complications to a minimum.

This brings us to the consideration of hysterectomy, an operation that even a few years ago was regarded as one of the gravest. Many methods have been devised by numerous operators, for the disposal of the stump, each striving to reduce the rate of mortality. The necessity for the operation is sometimes an unexpected sequence in cases in which it is impossible to remove the appendages, or when an edematous myoma is present. For these reasons it becomes an interesting question to decide what method promises the best results.

In order to arrive at some definite conclusions in this matter, I sent a circular letter to such operators as were known to me. I shall first give the results of those who have performed more than ten hysterectomies:

Dr. Joseph Price, 53 cases, 3 deaths, (5.6 per cent.), extra-peritoneal; Dr. John Homans, 45 cases, 8 deaths (17.7 per cent.), 39 extra-peritoneal, 5 intra-peritoneal; Dr. P. F. Mundé, 12 cases, 4 deaths (33 per cent.), extra-peritoneal; Dr. M. D. Mann, 12 cases, 1 death (8.3 per cent.), extra-peritoneal; Dr. H. T. Byford, 21 cases, 4 deaths (19 per cent.), vaginal fixation, abdominal fixation. The aggregate of fifteeen operators who have performed less than ten hysterectomies by the extra-peritoneal method includes 46 cases, with 10 deaths, or a mortality of 21.7 per cent. By the intra-peritoneal method five operators operated in 15 cases, with 5 deaths, a mortality of 33.3 per cent. Considering the number of operators, this latter compares favorably with the record of Leopold's 56 cases: 22 cases, with 5 deaths (22.7 per cent.), intra-peritoneal; 34 cases, with 7 deaths (20 per cent.), extra-peritoneal. The mortality of hysterectomy in England and America, as represented by the labors of two leading surgeons, stands thus: In his last 1000 cases, Lawson Tait had 88 of hysterectomy, with 10 deaths, a mortality of 11.3 per cent., and a series of 31 consecutive recoveries. Joseph Price has had 53 cases, with 3 deaths, a mortality of 5.6 per cent., and a series of 43 consecutive recoveries.

The improvement in the last few years is quite manifest when we refer to Bigelow's[1] statistics that show that the mortality of operations performed by the extra-peritoneal method was, during the preceding five years (from 1879 to 1883 inclusive), 36.54 per cent., and that during the years from 1881 to 1883 the mortality was reduced to 26 per cent. This excludes all cases in which only portions of the uterus were removed, and includes all those in which the uterine tumor and appendages were removed.

Bantock's success has increased in direct ratio with his improvement and skill in the perfection of the extra-peritoneal method, his few cases of intra-peritoneal treatment having ended disastrously. In his paper on the "Treatment of the Pedicle in Hysterectomy,"[2] he reports 5 cases treated intra-peritoneally, with 4 deaths and 1 recovery; while he reports 57 cases treated by the extra-peritoneal method, with 45 recoveries and 12 deaths; and, in another series, 13 cases with no death.

Martin has lately abandoned the intra-peritoneal method, feeling that there is not sufficient security against secondary hemorrhage, the discharge of suture-threads from the stump and the liability to septic infection from the cervical canal often retarding recovery. He has performed 135 supra-vaginal amputations of the uterus, with 46 deaths, and has now concluded to remove the cervix with the uterus, thus overcoming the source of danger.[3]

Dr. H. T. Byford has endeavored, and it seems successfully, to retain the cervix, and yet remove it from the pelvic cavity by his method of vaginal fixation, and at the same time retaining that which, as he ably expresses it, "is the keystone of the pelvic roof structure." He reports 14 cases treated by this method, with 1 death.

Dr. H. A. Kelly[4] sutures the face of the stump as Schröder recommends, but suspends it in the lower angle of the wound. In a personal communication he says: "I think I know about how many cases I have had after my own method—16, with 1 death. This death was reported in my fasciculus on Gynecology, *Johns Hopkins Hospital Reports*, p. 122. You will find another death reported on p. 120, in a case in which I was unable to follow my method, as the whole uterus was involved in the tumor." The 16 cases mentioned are not all included in this hospital report, but there is a report of 6 cases, with 3 deaths;

[4] *Vide* THE MEDICAL NEWS, June 28, 1890.

probably the third death was another in which he could not follow his own method.

In summing up the results of the various methods, we find that the extra-peritoneal treatment has found greater favor, because of its safety from hemorrhage, the more rapid and certain convalescence, and, if carefully carried out, the danger of septic infection being almost *nil*.

I feel certain that, with all due respect for the surgical skill of Dr. J. Price, if he was not so extremely careful to attend to *all* the smaller details his work would not have been crowned with such remarkable success as it has been.

PROTECTION FROM DISEASE.[1]

By WILLIAM B. CANFIELD, M.D.,
of Baltimore, Md.

When a physician attempts to cure disease, he simply, as far as possible, removes the cause, clears the way to recovery, and lets Nature do the rest. In many cases Nature does her work well, although not always getting due credit for warding off disease and protecting us from harm; in other cases, she succumbs to her stronger foe, disease. Those of us who live in crowded communities are surrounded by an invisible enemy, and with every breath we are liable to draw in disease in some form —and yet so many escape! We open our windows and let in what we call "fresh air," and as the sunbeam slants across the room, what myriads of dusty atoms meet our eyes! If in a quiet room we inhale at every breath this dust, what would we not breathe in the streets of dusty cities, in mines, and in mills! In the sanitary management of our cities, the danger of flying dust, with its many impurities, is rarely considered, and the dust of city streets that should be properly sprinkled and carted away is simply stirred up by the indolent sweepers and much of it is probably taken away in the clothes and breathing apparatus of the unfortunate passers-by. Such dust, when inhaled, does harm both from the impurities it may contain, and, when present in appreciable quantity, from its mechanical action and irritation.

That germs float in the air, even in the most secluded spot, the careless housewife knows to her sorrow when she leaves her jelly-glasses uncovered for a short time and finds the surface covered with a beautiful mould. Bacteriology has told us that the germs of some contagious diseases are found in the air and may be inhaled and produce disease. Thus diphtheria, glanders, measles, whooping-cough, hay-fever, pneumonia, and consumption are all undoubtedly in part due to the inhalation of dust containing the germs of these diseases. If, then, the germs of disease are in so many forms floating in the air, it is strange indeed that so many escape, especially when we consider the crowded public and private rooms, cars and other places where the sick and well meet together and breathe the same air. Fortunately for us, Nature has erected a series of barriers against such an enemy as inspired dust, and in exposing us to this danger, has given us certain means of protection that repel attacks not unusually severe.

In persons who breathe as they should, all inspired air passes first through the nostrils and is thus not only warmed to the proper temperature for the throat and lungs, but the moist walls serve as a sieve by which the air thus inhaled is as far as possible relieved of dusty impurities. This shows at once the importance of breathing with closed mouth, especially in passing from a heated to a cooler atmosphere, and of always thus breathing in an atmosphere of visible dust. The moist walls of the lining membrane of the nasal cavities fill the inspired air with moisture, making it more agreeable to the throat and lungs.

The nasal passage in almost every animal deviates from a straight channel, and this is according to the needs of the animal. In man, who is upright and far from the ground, the passage is only slightly curved and may almost be considered rudimentary in its development. In birds, which fly far above the earth, the nasal passage is almost straight. In all quadrupeds, and especially in those that graze or seek their food on the ground, and those exposed to sudden changes of temperature, as in amphibious animals, the nasal passages are exceedingly tortuous and in a high state of development, and their extreme moisture, due to the active secretion of their lining mucous membranes, serves, as far as possible, to catch and stop the entrance of dust into the throat and lungs. This is familiar to us in the cold nose of the dog, cow, etc., and in the constant sneezing of the horse. Those who breathe abnormally, with open mouth, are much more liable than others to diseases of the throat and lungs. In spite of the outward defence we have in the nose, dust and foreign substances do occasionally get into the throat and trachea, but the latter is so very sensitive to the slightest irritation that the presence of such foreign substances excites a cough and they are quickly expelled. The minute anatomical structure of the lining membrane of the trachea is, as we know, much like the waving surface of a wheat-field. The whole surface of the trachea and larger lung-tubes is covered with ciliated epithelium the waving motion of which is from the lungs upward to the throat, and very minute particles of dust and foreign

[1] Read before the Medical and Chirurgical Faculty of Maryland at its semi-annual meeting, held at Cambridge, Md., November 12, 1890.

substances that find their way into this region are thus gradually removed. This membrane is also active during sleep, as many throat sufferers and others may have noticed from the fact of their "morning cough" on rising.

In spite of these defences which Nature has raised against her enemies, disease-germs and foreign substances find their way into the trachea and even to the ultimate ends of the finest lung-tubules. In this way disease-germs, and especially the tubercle bacilli, get into the lungs, and in those predisposed to this disease this organism easily thrives. From recent investigations in microscopical anatomy we now know that Nature does not give up even after these foreign substances and disease-germs find a place in the body. In the organism, and more particularly in the blood, there has long been known a cell or corpuscle called the white blood-corpuscle or leucocyte, and in suppuration the same cell is recognized as the pus-cell. That this cell seems almost ubiquitous in the body and that it assumes different rôles under different circumstances has also been the subject of repeated investigation. The most recent function now assigned to this cell is that of a "carrier cell," scavenger cell, or phagocyte, because its function has been learned to be that of devouring or carrying off germs and foreign substances. This was noticed in those who worked in dusty atmospheres. The dust was inhaled in such quantities that it got into the lungs, and, as it could not all be coughed up, it worked its way into the lung substance, where, by irritation, it attracted these carrier cells or scavengers, and, as far as possible, these promptly attacked the particles and carried them either to the nearest lymphatic gland, where they would be quiet and harmless, or the dust-containing cells found their way into the lungs and were coughed up. This has been repeatedly noticed in the case of coal miners, in whose expectoration large numbers of these cells were found, and in those cells bits of coal-dust could be easily recognized. In some cases in which the piece of dust was too large for one cell to devour, two or more would join together and close around it. These cells have certain movements, called amœboid, from their resemblance to the movements of the amœba, one of the lowest forms of life, and found on the surface of fresh-water ponds. These amœboid movements consist in a change of shape on the part of the cell by which it thrusts out a part on one side and draws in another part, and by thus changing its shape it surrounds the substance and assimilates it. That these cells endeavor to do their work as well as possible is shown by the fact that years after miners have ceased to work in coal mines, it has been noticed that the expectoration remained dark and a microscopical examination showed these cells to be full of bits of coal and pigment, thus proving that the carrier cells were still trying, as far as possible, to remove the foreign substances. This has been experimentally demonstrated by introducing finely divided organic substances, such as powdered cinnabar, into the tissues and lungs of an animal, and after a short time microscopically examining the tissues and glands of the animal, when these carrier cells are found loaded down with this red pigment. This is especially true of the cells in the glands.

In all these cases the rôle of the foreign substance is undoubtedly passive while the cell is active. Further study of these cells showed that they act antagonistically to pathogenic bacteria—that between these cells and the bacteria there is a struggle for existence or supremacy, and on the result of the struggle depends a condition of illness or health. These observations were first made on a disease produced by a fungus in a fresh-water crustacean, the daphnia, a "water flea." The fungus swallowed by the crustacean produces spores that pierce the intestinal wall, enter into the tissue and are at once surrounded by these phagocytes. Here a struggle takes place that results in a victory for the cells, the latter closing around these fungus spores, devouring them and finally destroying them by a process of "intra-cellular digestion." In this case the action is very simple, but in the case of other animals and man the process is not so simple.

A careful study of these bacteria, both biological and chemical, has fully proved that they exert their deleterious action not so much by their actual presence as by a poison or ptomaïne that they secrete from their minute bodies, and that each specific bacterium or bacillus has its own peculiar body-product which, in the case of pathogenic or disease-producing germs, is a poison. This then complicates the struggle between the bacteria and the body-cells. There is then an actual life-and-death struggle between cells and bacteria. Inoculation of a frog with the bacillus anthracis showed this struggle very beautifully. A study of the cells of this frog revealed them with bacilli and parts of bacilli within the cell-wall in process of digestion or disintegration.

Thus there is good reason to believe that in the presence of a contagious or infectious disease, the germs floating about, or in some way gaining access to the individual near by, find their way into the body and there a struggle takes place between them and these cells that are attacked by the invaders. Now begins a struggle for supremacy. The cells close around the attacking hosts and endeavor to destroy them and carry them off or at least to prevent the further ingress of the bacteria. If the cells are victorious, they devour the germs, carry them away and thus the individual escapes the disease.

But, if the germs increase too rapidly and, by the secretion of the poison or ptomaïne from their bodies, cause the death of the cells, then sickness results. In this case the accumulation of these carrier cells that are killed by the germs results in suppuration, for the cells of pus are but the white blood-corpuscles, leucocytes, or phagocytes, when dead. As heat increases the motion of these carrier cells and also their protective activity, the rise of temperature that precedes and accompanies suppuration has been looked upon as an attempt on the part of Nature to assist the activity of the cells and to destroy the invading bacteria.

Immunity from second attacks of certain diseases, as well as the protective influence of certain inoculations and vaccinations, has never been clearly understood, although various explanations have of late been offered. In all probability, although this is but a theory sustained by analogy, after recovery from the contagious disease, usually occurring but once, the bacteria are supposed to secrete some morbid virus that hinders their own life, just as animals produce carbonic acid which is poisonous to them, or the yeast-fermentation produces alcohol which stops the growth of this fungus. In the same way, after these attacks, the cells of the body are supposed to contain some substance that resists the second attack of those organisms. It may be that Koch's paratoloid, when injected under the skin of tuberculous patients, acts in the same way. The strength and duration of this immunity differs in individuals. Of course, the ability of these cells to struggle with bacteria is lessened in weakened individuals, and hence, for example, it is very probable that the lowered vitality caused by being chilled below the recuperating point invites an attack of pneumonia or some other disease, not from the mere chilling, but from the weakening of the strength of the cells. In hereditary diseases the predisposition plays an important rôle.

We thus see that before Nature succumbs or yields to what has been very wisely called an "attack" of a disease, she uses various means of defence—and, fortunately for us, often comes off victorious.

IS ANTISEPSIS A FAILURE?[1]

By GEORGE ERETY SHOEMAKER, M.D.,
OUT-PATIENT SURGEON TO THE UNIVERSITY AND PRESBYTERIAN HOSPITALS.

Strange as it may seem, outside of a comparatively small circle of surgeons, from time to time there are heard suggestions, which occasionally appear in print, that the system of Listerism, so called, is a failure. It is not very uncommon to hear someone say that in a given case "every antiseptic precaution" was adopted, but the result was bad. The speaker would have one believe that he had done his part, and that it is the whole system that is unsatisfactory. Now it is worth while briefly to consider where the difficulty lies; and without entering upon a discussion of asepsis as opposed to antisepsis, of absence of dirt *versus* sterilization of dirt, without advocating special methods or dressings, attention may be drawn to the practical difficulties that interfere with success and lead to misunderstanding.

A few men like Mr. Lawson Tait vigorously attack the so-called theory of "Listerism," while they themselves carry out the principles underlying its success. The reputation of Mr. Tait, however, rests upon his operative work, and not upon his opinions or his explanations of his success. When, in characteristic style, he says (*British Medical Journal*, September 27, 1890, p. 728): "The tone and attitude adopted by Sir Joseph Lister, at Berlin, clearly show that the whole sad business is on its last legs;" and, again, when he refers to "his [Lister's] old dead theory," and to the new cyanide dressing as "the last phase of this astonishing craze" (p. 732), the harm that he does is not great among men who, especially in general surgery, are doing the best work. These cannot work for a day without discovering for themselves that their results are better or worse according to their microscopical and chemical cleanliness in operating. Active surgeons do not care how Mr. Tait explains his good results. He might refuse to accept the law of gravitation, if he chose, but so long as he did not violate it, so long as he refrained from walking out of windows or off precipices, his opinion of the law would matter little. Most men care little that he denies the evil potency of germs, and relies on removing decomposable material from his wounds; they remember that he deals with a peculiar membrane and its neighborhood, that he is punctiliously clean in his work, and they will permit him to attack Sir Joseph Lister personally and his impregnable principles to his heart's content—those principles meanwhile receiving the widest practical application.

The harm Mr. Tait can do is in unsettling the mind of the man who is beginning his work; and, worse than that, his writings tend to salve the consciences of those who have had no training in genuine aseptic methods, who fail consequently to carry them out, and who joyfully hail any champion who even seems to justify their indifference.

But even among a better trained class of men, does not one often see a lamentable failure to grasp the essential ideas of surgical cleanliness? There are to-day hundreds that apparently persuade themselves that mopping a 1:20 carbolic acid, or 1:1000

[1] Read by title before the Section of Obstetrics and Diseases of Women, American Medical Association, May, 1891.

"bichloride" solution rapidly about a wound-area constitutes, as the phrase goes, using "every antiseptic precaution." There are men who will use chemicals on a septic patient and not change infected bedding. There are men who will go to an operation with the joints of their scissors, the locks and serrations of their hemostatic forceps, the eyes of their needles, choked with dried blood, or worse material, from the last operation. They never boil an instrument; their conscience is satisfied with the carbolic acid in the instrument-pan. Some men wash their hands no better before an operation than before dinner. When an instrument or a sponge drops to the floor they may rapidly rinse it and use it again. There are other men who have trained nurses, sterilized dressings, and boiled instruments, but who, after they have washed for the operation, shake hands with a spectator, put a hand in a pocket, remove instruments from an old, blood-stained case, help carry a table, handle dusty bottles, or use a handkerchief—yet say they use every antiseptic precaution. These men know better. What is lacking is careful self-training and what may be called an aseptic conscience. What is wanted is a realizing sense of the difficulty of getting things clean and of keeping them so. Bichloride covers a multitude of sins when it can be used freely, but when it cannot be so used carelessness tells in abdominal surgery.

Carbolic acid solutions as practical sterilizers are a delusion and a snare. They at best work slowly. Unless too strong for comfortable or safe handling, they do little good, and they do enormous harm by quieting the conscience of the man who ought to spend more time washing his hands; yet how many times does one see them relied upon when they only cover dirt. Many text-books, especially revised editions of the older works, are written from a carbolic acid standpoint. Antisepsis is a failure when it is superficial.

In a recent case of laparotomy, referred to by the operator's permission, the stitches cut out and the wound opened, though it afterward closed by granulation. The operator had been cleanly, but the fault was traced to a nurse who had handled the silk with infected fingers.

In another case the paraphernalia were elaborate and the preparations minute. During the operation the chief assistant seized a falling ether bottle, old and very dirty; yet, without the slightest effort to cleanse the hand, it was soon in the abdominal cavity. The patient died two days later of peritonitis. It may have been a mere coincidence.

In a vaginal hysterectomy case by a very active surgeon, many proper precautions were taken to secure external asepsis, but at the close of the operation *five spectators in turn*, with unsterilized hands, examined the wound, while the operator did not follow this exposure even by a douche.

A few days ago, in a hospital, a major operation was in progress. The lecturer had dilated upon the beauties of the antiseptic method. His catgut proving defective, an ancient open box of unprepared silk was brought. An unwashed hand threw a quantity into the instrument-pan, from which a piece was taken when scarcely wet, to be immediately placed upon one of the largest arteries in the body. A weak link breaks a strong chain.

In a hospital case of my own requiring careful dissection about the face, an assistant unobserved obtained an instrument used a few minutes before in laying open a suppurating bubo. In two days the wound-area underneath the sterilized dressing was one large abscess.

In an emergency, lately, the writer asked at a drug-store whether they had antiseptic gauze. "Oh, yes." And, before a word could be said, the druggist had opened a large tin box beautifully decorated, and had unrolled a quantity for inspection. He was, of course, told that while that might have been antiseptic gauze once, it had been ruined as such by his handling—a proposition that completely failed to enter his mind. No doubt that identical roll of gauze has since been retailed (part of it had been sold already), and it is to be feared that there are physicians who would buy it measured by the yard at his counter, yet hardly realizing that as a clean dressing or packing it was utterly worthless. But why multiply instances to show that antisepsis, when neutralized by some single mistake, is a failure. Which should be blamed, the system or the application?

The war between asepsis as opposed to antisepsis is a minor issue. The great fact remains that the principles of cleanliness underlying both, though adopted theoretically throughout the world, are really carried out most imperfectly by the majority of hospital internes, nurses, and some general practitioners in town and country, and, it must be said, even by many otherwise most excellent and estimable surgeons. Let no man venture to criticise methods that he has never fairly tried; let each also bear in mind that through his lack of patient personal training, though honest, his trial may be superficial, and therefore faulty.

Then, in answer to the question, When is antisepsis or asepsis a failure? one may say: *Never*, if real; *always*, if imperfect. There is no doubt that the great principle of cleanliness in surgery, whether obtained by soap, hot water, dry heat, or chemicals, has "come to stay," and the sooner all concerned act upon that principle and ignore personal discussion, the better it will be.

3727 CHESTNUT STREET.

TWO AVOIDABLE CAUSES OF STILLBIRTHS.

By PETER McCAHEY, M.D.,
of Philadelphia.

Statistics show that fetal mortality has not appreciably diminished during the past century. Now, as in 1791, the proportion of stillbirths to children born alive is as 1 to 30. Out of 750,000 children born in the United States every year, 25,000 are dead when born. This is exclusive of premature births, and the multitude of abortions, accidental and intentional.

When we reflect upon the national loss implied by these figures, and upon the anguish inflicted upon the mothers who have borne so much travail only at last to behold the inanimate bodies of their children, it would seem incumbent upon us to try to lessen this frightful mortality. To do this, the principal causes of stillbirths must be recognized. Jörg and other observers, and recently Dr. M. Richardiere (*Gazette des Hôpitaux; New York Medical Journal*, July 18, 1891), have noted that "meningeal hemorrhage constitutes one of the most frequent causes of death in the newborn," that the meninges are highly congested, that sub-pleural extravasations are frequent, and that there is no evidence of any previous inflammation.

Now, it is a curious fact that the post-mortem appearances thus noted in the large majority of stillbirths are almost identical with those found in men dead after having been subjected to high atmospheric pressure in caissons. Dr. Jaminet, the medical supervisor of the men employed at the St. Louis bridge, in his work on *The Physical Effects of Compressed Air*, states that in all the post-mortem examinations of the dead caisson employés "the brain and cord were highly congested, overcharged with blood."

Dr. A. H. Smith, of Brooklyn, who was the medical director of the men employed in the caissons during the building of the Brooklyn bridge, in his work on *The Effects of High Atmospheric Pressure, Including the Caisson Disease*, says: "The constant lesion in fatal cases of caisson disease is congestion of the brain or spinal cord. . . . This congestion may affect both the meninges and the substance of the brain and cord. Extravasations of blood, hypostatic congestion of the lungs, congestion of the abdominal viscera are also noticed."

If to these observations it be added that the fetal heart is slowed during the contraction of the uterus and that the adult pulse is slowed in the caissons, there is nothing wanting to show that the cause of death in both classes is the same—exposure to the influence of compressed air.

There is, however, another cause of fetal death during labor—the filling up of the air-passages with the residual liquor amnii, mucus and meconium. Buhl (*Year-book*, 1864, p. 415) stated that his "post-mortems of twenty-seven children, dying during or shortly after birth, demonstrated that eleven of them were destroyed by obstruction of the air-passages with meconium and mucus." It is probable that in some of these cases the meconium floating in the liquor amnii was drawn into the trachea by premature inspiratory movements, but in others it was doubtless forced through the mouth and nose by the same force that in the mother ruptures the uterus and the perineum, and disarticulates the pelvis, and in the child causes meningeal hemorrhage, cranial fractures and other severe lesions—the unrestrained force of the heated and compressed uterine air.

Both of these sources of danger to the fetus can be reduced to a minimum by the use of an intra-uterine safety-tube, first, to draw off the residual liquor amnii, so that none of it may remain to be forced into the air-passages of the child; and, secondly, to lessen the intra-uterine air-pressure, whenever it appears to threaten danger to either the mother or the child.

Previously to my employment of such a tube, I noticed that in cases in which there was apparently a great deal of residual liquor amnii, the children had "phlegm in the throat" for days and, in some cases, had a cough for weeks. In "dry labors," however, and in others, in which all the liquor amnii was apparently discharged when the membranes ruptured, the children had "no phlegm in the throat," neither were they troubled with a cough.

1413 South Tenth Street.

CLINICAL MEMORANDUM.

TWO CASES OF PYO-PNEUMOTHORAX.

By CASPAR W. SHARPLES, M.D.,
of Seattle, Wash.

A. D., thirty-nine years old, made application for admission to the poor-farm, giving in brief this history:

He was a cook in a large hotel and subject to many sudden changes in temperature. Four months previously he began to cough. In addition there developed shortness of breath, hectic fever, night-sweats, etc., together with other phenomena of phthisis.

There was percussion flatness over the lower portion of the right lung, suddenly changing to hyper-resonance, and dulness over an area nearer the mid-sternal line, as well as posteriorly. Two weeks later the patient died. At the autopsy the pleura was found much thickened and distended with gas and fluid. The gas, as it escaped, on the application of a light refused to burn. The fluid consisted of two quarts of thick, offensive pus, as well as a large quantity of lymph at the bottom of the sac, the lung being adherent to the costal pleura by two bands. The lung was firm and compressed, expanding but little

on attempts to inflate it. As the air was forced into the lung, pus and air escaped from two of three visible openings that communicated with a large cavity. The largest opening or perforation was at the antero-inferior portion of the upper lobe and was one-half by three-quarters of a centimeter in size. A bristle introduced at this point and passed upward and backward, at a distance of five centimeters, reached the second opening, one centimeter below which, in turn, was found a third. Each of the latter was quite small, having a diameter of not more than one and a half millimeters. There were thus three distinct perforations of the lung, all communicating with one tuberculous cavity. Also noteworthy are the rapid progress of the case and the occurrence of pyo-pneumothorax in so short a period.

The second case was of a year's duration and presented nothing of special interest except the trabeculæ running through the fluid at every point. In number there were about twenty-five—some binding the costal pleura to the lung, others the diaphragmatic pleura to the lung, and still others attached to both the costal and diaphragmatic pleura, forming the bases of triangles.

The cavity had a capacity of three and a half quarts, and contained five pints of pus and lymph. In this case, as in the other, the escaping gas did not burn on the application of a light. The perforation was one centimeter in diameter and represented the extremity of a tortuous cavity passing through different parts of the lung. This cavity was at no place of large diameter.

ORIGINAL LECTURE.

VARIETIES OF CHANCRE—THE PRECORDIAL UNEASINESS OF SYPHILIS—ALOPECIA—SYPHILITIC ERUPTIONS, THEIR DIFFERENTIAL DIAGNOSIS AND TREATMENT.

Abstract of a Clinical Lecture
delivered at the New York Post-Graduate Medical School.

BY ROBERT W. TAYLOR, M.D.,
PROFESSOR OF DERMATOLOGY AND SYPHILIS.

THE first patient presented to the class was a man, twenty-three years old, who four weeks before, in a fight with another man, had been bitten on the lip. The slight break in the skin did not heal, and about one week later the lip began to get worse and swell. At present there is on the upper lip a large, sharply limited ulcer, the surface of which is excoriated, distinctly elevated and papillomatous; the ulcerated portions are of a grayish color, but the margins are of a brownish tint; there is some induration, but it is not marked. In reply to the inquiry by one of the class whether the lesion was a chancroid, Dr. Taylor said: Chancroid can almost be excluded by the great rarity of chancroids of the lip, not more than forty cases of the kind being on record. Among that number was one reported by Dr. Taylor about seventeen years ago. In this case the lesion is an exuberant one, and not in any sense of an ulcerative character. A history of a bite on the lip, which instead of healing up becomes the seat of a hyperplastic growth, is always extremely indicative of syphilis. If the sore were a chancroid, the surface would be ulcerated and depressed, instead of being, as in this case, the seat of thickening and new growth. The lower lip is the more common site for chancres upon the lips. Again, this case presents marked enlargement of the cervical glands; it is a rule, to which there are few exceptions, that the glands in the immediate vicinity of the port of entry of the syphilitic virus are those that are most affected. In certain cases that have been reported as peculiar and rare for the reason that the cervical ganglia have been greatly enlarged, the initial lesion was in all probability seated on the tonsil, where it had escaped detection. Had chancres been about the tongue or tonsils, there would most probably have been such an enormous glandular enlargement as to constitute deformity. If the cervical glands only are enlarged, one would expect a lesion of the oral cavity. This patient is in the primary stage of syphilis; hence it is too early for general manifestations. Chancres of the lips are not at all uncommon; patients will frequently seek advice for a cold sore which they say will not heal. Examination in the early stages shows the sore to be doughy, although later on induration is present. Any such persistent ulceration about the lips is indicative of syphilis rather than of cancer, particularly in persons under forty years of age. The syphilitic sore will be much more rapid in progress than cancer, and it will be accompanied by early and great enlargement of the cervical glands, while in the vast majority of cases the age of the patient is in itself sufficient to exclude cancer.

The patient must first be made to understand that he is a contagious element in the community, and that he must have exclusive spoons, knives, forks, drinking-cups, tobacco-pipes, towels, and the like. The local treatment is to apply equal parts of Lassar's paste and blue ointment, as a plaster, to the lip, to be changed as often as contaminated with the secretions. Externally, mercurial ointment is early and imperatively demanded; for, in this case, it will not do to await the development of secondary symptoms. The treatment should consist of inunctions of thirty grains of the ointment once daily for six days, then to be omited for two days. The inunctions should be applied to the upper part of the body and neck until there are indications of an erythema or an eczema, for it is of the first importance that the lymphatics in this region should be both promptly and efficiently treated.

The next patient, a man, twenty-seven years old, stated that three months before, two weeks after coitus, he had noticed a sore on the penis. Examination showed in the middle of the dorsal surface of the penis a slightly indurated sore, the edges of which were covered with a scab. There was also balanitis and gonorrhea. The patient denied having previously had any eruption, but stated that during the month before he had suffered from nocturnal headaches and pains in the bones. In addition to this, he had severe pains in the chest, increased by deep breathing or upon exertion, together with pains in the submaxillary glands, aggravated by movement of the jaw.

About seventy per cent. of all chancres upon the skin of the penis are syphilitic. This patient has what is known as an ecthymatous chancre, *i. e.*, one presenting a crust surrounded by a reddish halo, and with no evidence of any activity. This lesion usually begins as a

papule or as a slightly excoriated patch. After a while the infiltrated patch becomes reddened, and a serous or sero-purulent discharge takes place and dries into a crust. This patient says that this chancre has remained for the past two months just as it is. It is an illustration of a moderately hard chancre. In what is known as the "mixed chancre," chancroidal pus is deposited upon a hard chancre, giving rise to active destruction; in other words, a chancroidal influence is superadded to the hard chancre. Dr. Taylor laid stress upon the fact that hard chancres of the skin of any part usually appeared as scaling papules or as moist papules or patches that become excoriated and to which the term ecthymatous chancre is applied.

This patient says that he has suffered from pains in the chest and a smothering sensation in the precordia; in some cases the suffering is so severe as to require the administration of opiates; yet an examination of the heart and lungs detects no morbid condition. The trouble probably arises from disturbed innervation of the celiac axis or of the cardiac plexus. At times, the pain is in character and severity not unlike that of angina pectoris. This patient has been given a mixture of diffusible stimulants with the object of excluding pains that might be due to a cardiac affection. As expected he has not derived any benefit from the medicine. A change to mercurial treatment by inunction will undoubtedly give speedy relief.

The next patient was a woman, twenty-four years old, who said that three months previously she had first noticed a small sore near the groin, which afterward became ulcerated. Examination showed an ecthymatous chancre at the inner side of the thigh, about two inches below the vulva. Chancres are also found about the hypogastrium; when found in such unusual situations they point to infection during sexual intercourse in some peculiar position. This woman was probably infected from numerous patches or condylomata on the scrotum of her consort. The eruption appeared about six weeks ago, and she suffered somewhat from nocturnal headaches; but the most striking feature of her case is the extensive and profuse alopecia, affecting not only the scalp and eyebrows, but even the legs and mons veneris. The alopecia in this case has appeared quite early; it is usually first seen in the third month of the disease, after the eruption is well developed and the patient begins to feel weak and to lose flesh. It is also usually gradual in onset, the hairs loosening and pulling out readily; the hairs, when examined, are seen to be thin and dry and show no bulbous expansion upon the ends. The scalp often looks quite dirty and more or less scurfy, although its condition may readily be overlooked. Sometimes there is a partial loss of the hair of the eyebrow; sometimes there is a splitting just over the supra-orbital notch, or the hair falls out leaving jagged spots, and bearing some resemblance to alopecia areata. The papular, pustular, or ulcerative lesions about the head lead of course to more or less loss of hair. As alopecia may follow any long-continued adynamic disease, the history of the case is an important aid in diagnosis.

One often hears the unfortunate statement that when a physician is giving mercury internally, he is doing his whole duty; but this is not true, for it is of vital importance to combine local with general treatment. The prognosis is often said to be bad in these cases, and so it may be, if internal treatment alone is employed; but when both methods are combined, even severe cases, like this one, are likely to have their hair restored.

After thoroughly cleansing the head, it is to be washed two or three times a day with a 1 : 2000 or even 1 : 1000 solution of bichloride of mercury; and once or twice daily the following lotion is to be vigorously rubbed into the scalp:

℞.—Tinct. cantharidis . . . 1 ounce.
Tinct. capsici . . . ½ ounce.
Aquæ . . . . ad 4 ounces.
Misce et ft. lotio.

In private practice, it is well to add a little Cologne water. Internal mercurial treatment has been instituted for some time.

The attention of the class was next directed to a young man, a bartender, twenty-two years old, who illustrated the form of eruption known as a miliary papular syphilide. Two months after coitus, or six months ago, a single sore, having an indurated base and discharging pus, appeared on the penis; two weeks later, a papular eruption suddenly appeared over the entire body. This subsequently became pustular, then squamous. He has had no alopecia, but suffers from headache, sore-throat, pains in the bones, and is rapidly losing flesh and strength.

This miliary papular syphilide consists of a syphilitic infiltration around the hair and sebaceous follicles, resulting in the formation of small papules; on the apices of some of these are found purulent crusts. This condition was formerly, although very improperly, described under the name of "syphilitic lichen." Similarly, if a patch filled up with papules becomes irritated, the eruption becomes masked, and the result is what was formerly known as "syphilitic eczema;" but these are only cases of syphiltic eruptions simulating other eruptions, and the nomenclature therefore is faulty. The headache, a result of hyperemia of the meninges, is referred to the convexity of the head, as in this patient; it sometimes involves the frontal and supra-orbital regions, or the area of distribution of branches of the fifth nerve. The pains in the bones are due to a mild hyperemia of the periosteum. Mercurial pills might be given this patient for a long time without much effect. He is now having baths followed by mercurial inunctions.

Another variety of eruption was found in a woman, twenty years old, in whom the initial lesion had appeared two months before as a sore on the genitals. She has had no alopecia, but she suffers from nocturnal headaches. Six months ago, a rash appeared in single points, which afterward coalesced, and still later became scaly. At present the eruption might be mistaken by the inexperienced for a papular eczema; the importance of an early diagnosis in such a case is apparent. There is an absence of the redness, itching and general inflammatory symptoms seen in eczema; the eruption has lasted for several months without showing any disposition for the papules to fuse together. There is a slight tendency to the formation of rings. The eruption is usually present in one of the following forms, viz.: (1) in little groups, as seen in the last patient; (2) diffused in one or more regions, and (3) in the form of rings. This patient is

of good physique and will do well with proper treatment.

Dr. Taylor presented to the class still another form of syphilitic eruption, in a married woman, twenty-seven years of age, who about fifteen months before had had a round sore, with indurated edges, upon the genitals, that in about six weeks was followed by a general eruption. On admission to the Charity Hospital the body and extremities were found covered with scaly patches of rupia, that gave rise to so much itching as to necessitate the administration of morphine. There has been some alopecia; the headache, that has been quite troublesome, has usually begun about 11 A.M. and lasted into the night. Syphilitic headache usually begins toward dusk. Before admission the woman had been treated with mercury to the point of salivation. Since admission she had been treated locally with inunctions of mercurial ointment and washes of bichloride solution, and internally had received pills of bichloride of mercury. Dr. Taylor strongly disapproved of the administration of such pills, which served chiefly to irritate the stomach, and did not admit of putting the patient properly under the influence of the remedy. This case is an excellent illustration of the ravages of rupia, for there still remain upon the face and neck a number of large, hypertrophic cicatrices. Sometimes the burning, itching, lancinating and throbbing pains from these cicatrices are terrible. The eruption is usually extensive, particularly on the back and outer aspect of the legs. Under proper treatment, the scars will be replaced by thin parchment-like cicatrices, and as the hyperplasia leaves the scars these unpleasant symptoms will disappear. The suffering is probably due to peripheral irritation caused by the fibrous tissue contracting upon the ends of the nerves.

HOSPITAL NOTES.

WOMAN'S HOSPITAL, PHILADELPHIA.

CLINICS OF DR. JOHN B. ROBERTS,

Reported by DR. MARY E. ALLEN,
DEMONSTRATOR OF SURGERY.

1. Fatty Tumor of the Omentum; Removed by Laparotomy; Recovery—2. Tuberculous Abscess of the Abdominal Wall Simulating Malignant Disease of the Transverse Colon—3. Localized Suppurative Peritonitis Causing Jaundice; Cholecystotomy, Followed by Death.

1. FATTY TUMOR OF THE OMENTUM; REMOVED BY LAPAROTOMY; RECOVERY.

E. C., a married woman, twenty-seven years of age, gave a history of good health until within the last four months, when she began to suffer from weakness and general debility. Five weeks ago she noticed that her abdomen was beginning to enlarge. Since then it has rapidly increased in size, and incommodes her by reason of the pressure-symptoms and the weight of the fluid. On examination there were evidences of liquid that changed place as the patient shifted her position from the back to either side. There was also a well-defined, flattened, solid mass immediately under the abdominal wall near the umbilicus.

Dr. Roberts stated that the three most common conditions that give rise to ascites are diseases of the heart, of the liver, or of the kidneys. In this case, however, there was no albumin in the urine, nor anything to indicate disease of the kidneys. The heart-sounds were normal and thus that organ was excluded as a cause. There was no appearance of jaundice or enlargement of the liver, or other apparent derangement of that viscus. This condition might also be caused by tuberculous peritonitis or a malignant tumor. The presence of what seemed to be a solid mass against the inner surface of the abdominal wall seemed to point to the latter cause. An exploratory incision was, therefore, determined upon, and a very small opening made in order to insert the finger. Two quarts of fluid slowly drained off and a flat, solid tumor was found adherent to the anterior abdominal wall and the transverse colon. The incision was enlarged downward, cutting through the mass of the tumor, giving rise to some bleeding. The tumor seemed to be in the omentum, and was with great difficulty peeled off from its attachments to the parietal peritoneum and the transverse colon. A number of vessels were ligated before cutting them. After the removal of the tumor, the abdomen was thoroughly washed out with plain sterilized hot water until bleeding had ceased and the water returned clear. The incision in the abdominal wall was about five inches long, and was closed by silk sutures; a short rubber drainage-tube was introduced into the abdominal cavity at the middle of the incision and secured by a suture.

The peritoneum was markedly inflamed at the time of the operation, and adhesions that were readily torn had already formed between the coils of intestine. The chances were, however, so great that the case was malignant and that the tumor would return at an early date that no attempt was made to break them up. After the stitches were tied antiseptic dressings were applied and the patient placed in bed in good condition.

The operation was performed February 14, 1890, at which time her temperature was normal. There was very little rise of temperature after the operation, the highest being 101.2°. She made a very good recovery, sitting up in bed on the 8th of March, and was discharged from the hospital, well, on March 22d. The patient, eight months after the operation, called at the hospital in good health.

Microscopic examination of the tumor, made by Dr. Marie K. Formad and Dr. H. F. Formad proved it to be not a malignant tumor as was at first feared, but a lipoma of the omentum.

Death would certainly have ensued if this growth had not been attacked. The fact that omental growths are so frequently malignant has made surgeons feel very doubtful of permanent cure after their removal. This case makes the extirpation of omental tumors appear much more hopeful, since microscopic examination alone can determine their nature. Dr. Roberts had a few weeks previously assisted Dr. L. W. Steinbach to remove a growth that had exactly the same clinical characteristics, and was in the same way adherent to the anterior abdominal wall and had the transverse colon imbedded in it. This case, however, did not terminate so favorably. The woman left the Jewish Hospital in three weeks, apparently cured; but was readmitted a few weeks later and died soon after. The growth in this

latter case was supposed to be a sarcoma, though it is not known whether or not a microscopical examination was made.

2. TUBERCULOUS ABSCESS OF THE ABDOMINAL WALL SIMULATING MALIGNANT DISEASE OF THE TRANSVERSE COLON.

A. H., a colored girl, sixteen years of age, entered the hospital for an obscure swelling of the abdomen. She belonged to a tuberculous family, her father having died of consumption when she was four years of age. She had also lost a brother and a sister, but did not know the cause of their deaths. She herself seems to have enjoyed a fair degree of health from childhood, but for her age appears very undeveloped and has never menstruated, except a very slight show about a year ago.

She first became aware of something wrong with the abdomen about eight months ago. There was a tender spot in the abdominal wall on pressure when she stooped over the washtub. From that time the abdomen began to increase in size, and sharp pains would from time to time shoot through it. On admission she had a very poor appetite, and was also afraid to eat much because of the after-distress which food occasioned. She was, therefore, very anemic. The tender spot extended all around the umbilicus, and a considerable distance to either side. The urine was normal, as were the heart-sounds. There was tuberculous infiltration of the right lung. On entering the hospital she was put to bed and acid baths used over the liver and abdomen generally. Five drops of syr. ferri iodidi were given after meals. Her temperature on admission was 99.4° and continued above normal. It was, therefore, decided to make an exploratory incision and ascertain the nature of the swelling that in position and outline resembled a growth within the abdomen. Omental or colic malignant disease was strongly suspected.

She was accordingly etherized and prepared for operation with every antiseptic precaution. A very small incision was at first made above the umbilicus down to but not through the peritoneum. The mass could be felt below the fingers and toward the pubes, and the incision was accordingly increased downward. The incision was carried around and below the umbilicus, and when all the abdominal muscles or rather the tendons of these muscles had been divided, a cavity containing tuberculous pus was reached. The abscess was thoroughly evacuated, curetted, and washed out with filtered boiled water. It was a large cavity extending across the abdomen for about four inches on each side of the median line. The cheesy pus was contained in a space between the muscles and the peritoneum, which naturally was thicker than normal. Two drainage-tubes were used, extending to either side of the incision, and were secured in place by sutures. The incision was left open to heal by granulation and antiseptic dressings were applied. Two hours after the operation the temperature was normal and did not rise higher than 101.3° after the operation. The drainage-tubes were frequently washed out with a two and a half per cent. carbolic acid solution, and were removed February 16th, the healing of the wound having progressed favorably. After this it was washed twice daily with the carbolic acid solution and an iodoform suppository inserted each time. The patient was discharged well after a somewhat long convalescence owing to the large cavity that had to close up by granulation.

3. LOCALIZED SUPPURATIVE PERITONITIS CAUSING JAUNDICE; CHOLECYSTOTOMY, FOLLOWED BY DEATH.

A married woman, forty-two years of age, came first to the out-clinic of the hospital, on account of severe attacks of pain in the region of the gall-bladder. These attacks she had had periodically for sixteen years, and by good physicians they had been pronounced to be biliary colic. Nine months before, the paroxysms increased in severity, the pain radiating from the gall-bladder to the shoulder, and lasting for three or four days. They were only relieved by morphia. She had not at any time been jaundiced. She first noticed a lump in the side, after the attack nine months ago. Her first visit to the clinic was made on April 21st, at which time she was suffering much pain and was very much constipated. Purgatives were given with temporary relief. During a visit, three weeks after, she was suddenly seized with a paroxysm so severe that she was unable to leave, and was accordingly placed in bed in the wards. Cups were applied over the loins, and counter-irritation to the abdomen. Morphia was given hypodermatically. There was an excessively tender mass, about the size of a fetal head, in the epigastric, umbilical, and right hypochondriac regions. The urine contained albumin and biliary coloring matter. The temperature was 103°; pulse irregular and feeble, and counted 136 to the minute. Constipation existed. Light-colored stools were obtained by medication. Morphia was given when needed to relieve pain, and the cups and counter-irritants repeated when necessary. Sodium phosphate, ℥j three times daily, was ordered, followed by enemata of warm water and five grains of quinia in suppository, and spt. etheris nit., f℥ss in water, by the stomach every three hours. The patient was beginning to be jaundiced.

May 14th and 15th: Temperature 103.2°; pulse 120; jaundice deepening. Sodium phosphate replaced by half-teaspoonful doses of spirits of chloroform every two hours. On the 16th, ice-bag used for severe headache. Temperature 102.6°. Treatment continued the same. Stools remained small and generally colorless. One grain of calomel given on the 22d, and stimulation begun with whiskey, f℥ss in milk, three times a day. On the 27th, olive oil, in f℥ss doses, was substituted for the chloroform. The temperature remained at about 102°–103° in the morning and a degree higher in the evening. There were chilly sensations on the 27th.

An operation having been consented to as a last resort, the patient was thoroughly cleansed and etherized on May 29th. It was decided to make the incision in the right hypochondriac region immediately over the tumor, the more readily to reach the seat of trouble. The abdomen was markedly tympanitic, and the whole surface deeply jaundiced. No difficulty was encountered in incising the abdominal walls and very little hemorrhage occurred. When the peritoneum was reached it was found to be thickened and opaque. It was raised upon tenacula and incised, the omentum pressing into the opening immediately. Omentum and distended intestines were kept back by flat sponges and the gall-bladder brought into view. The gall-bladder was greatly dis-

tended, and yet was so bound down by adhesions as to make it impossible to bring it up sufficiently to stitch it fast before opening it. A trocar was, therefore, thrust into it after protecting the abdominal cavity by sponges, and about a pint of grass-green bile evacuated. Below the bladder, and binding it to the transverse colon and liver, was an inflammatory mass the nature of which was not made out at the time of the operation. The edges of the opening in the collapsing gall-bladder were kept elevated by catch forceps and the opening was enlarged sufficiently to explore the interior with the finger. The walls of the bladder were velvety and thickened, but no stone could be found, even after following the cystic duct with a probe and thoroughly exploring the course of the canal.

The reason for the great retention of bile and the universal jaundice was still obscure; and the operation was completed by sewing the edges of the opening in the gall-bladder to the parietal peritoneum along the edges of the abdominal incision, the margins of which were drawn in considerably because of the impossibility of loosening the gall-bladder from its adhesions. The abdominal cavity was carefully irrigated with plain boiled water and dried with sponges. Two drainage-tubes were placed, one running transversely, the other down toward the pelvis. A long drainage-tube of small caliber was also placed within the gall-bladder after thoroughly irrigating its interior. The orifices of all the tubes were protected by rubber dam and sponges, that in the gall-bladder being entirely separated from the others. Abundant layers of antiseptic gauze were placed about the wound after it was sutured and the whole kept in place with a many-tailed flannel bandage. The patient was put to bed in a fair condition and the foot of the bed elevated to encourage the flow of blood to the brain. She was comfortable during the afternoon, but during the night the temperature rose with the onset of acute sepsis and the patient died at 1.30 P.M. on May 30th.

An hour after death a partial autopsy was performed through the site of the operation, revealing evidences of extensive inflammation at some preceding period. The adhesions were very firm and the inflammatory mass that bound everything together was ascertained to be a peritoneal abscess containing about two ounces of greenish ill-smelling pus. No stones were found, and it was no doubt the pressure of this mass upon the gall-ducts that caused the retention of bile and the jaundice.

CURRENT LITERATURE.

EXCISION OF CHANCRE.

WICKHAM has expressed himself as strongly opposed to the theory and method of Jullien in the management of the chancre. The history of excision of syphilomata does not date back more than a dozen years. Wickham considers surgical interference with the chancre as useless. He gives a brief *résumé* of the article of Jullien that appeared in *L'Union Médicale*, 1891. The latter insisted that the excision should be total, it being requisite to invade healthy tissue, following the precepts that regulate operative procedure in the case of cancerous tumors. It is not necessary to produce general anæsthesia; an application of cocaine, or, better, an interstitial injection, will suffice. Wickham regards methodical excision as too painful an operation for cocaine anæsthesia, unless the chancre be situated upon the prepuce. Jullien observes that after the excision of a chancre the resulting cicatrix is scarcely, if at all, visible. Leloir, of Lille, however, holds that, save exceptionally, the result of the excision of a chancre is to produce only an apparent cicatrix. In the course of the last ten years Jullien has excised eighteen chancres. Only four of the patients seem to have been entirely cured of the general disease. The others have all presented manifestations of constitutional syphilis. Nevertheless, Jullien has concluded that "the excision of the primary syphiloma is an operation not only legitimate, but even useful, often beneficial, and at times heroic." In short, according to his view, the individual is not infected when the chancre appears. To excise the indurated chancre in its incipiency is to prevent the appearance of the secondary manifestations, or, at least, to attenuate them in great measure. Such a theory is seductive; demonstrated as scientifically correct, it would furnish a powerful lever in preventing the consequences of syphilis, at times so terrible; but a number of facts, experimental and clinical, are opposed to this idea. The consensus of opinion among syphilographers is also against such a theory. In 1881, Mauriac concluded that "excision is useless; that it does not constitute an abortive treatment for syphilis; and that it does not attenuate the immediate or remote consequences of this intoxication. In 1880, Quinquaud had three failures; Terrillon, one; Zeisel, five; and Klink, one. Many others have failed to secure satisfactory results. Vidal, Rollet, Diday, Brocq and others enroll themselves as opposed to the theory advanced by Jullien. Especially do these experienced writers reject the assertion that the manifestations of the secondary stage of syphilis are attenuated by the excision of the initial chancre. As Leloir has said, "the benign secondary manifestations are the rule; the grave, the exception." Wickham verifies the truthfulness of this assertion, as demonstrated during the eighteen months of his residence in l'Hopital du Midi. He asserts positively that syphilis is a general disease from the moment of infection. Experimental and clinical facts ill accord with the view of Jullien. Even in the cures reported by Jullien there are possibilities of error. In one, the tonsils were covered with a suspicious-looking eruption; in another, that had not been under observation for eight months, there was a chancrous ulceration of the frenum. In still another there was evidently an error in diagnosis, as the primary syphiloma appeared on the fifteenth day after the impure coitus. In only five instances were the secondary manifestations modified in their intensity. Wickham cites the experiments of Fournier, who, in 1856, inoculated with syphilitic virus patients in the case of whom chancres had been previously excised; the results were negative; this would indicate that the chancre is not a local lesion, but the manifestation of a general condition. Wickham also quotes the results of the experiments of Ricord, formerly a strong partisan of the abortive treatment of syphilis by cauterization. Ricord concluded that cauterization and excision were both entirely useless in preventing general infection of the system.—*La Médecine Moderne*, 1891, No. 10.

THE GERMICIDAL PROPERTIES OF CORROSIVE SUBLIMATE.

As the outcome of experiments conducted in the pathological laboratory of the Johns Hopkins University, Abbott (*The Johns Hopkins Hosp. Bull.*, April 12, 1891) has found "that, under the most favorable conditions, a given quantity of sublimate has the property of rendering inert only a certain number of individual organisms—that is to say, the process is a definitely chemical one, taking place between the protoplasm of the individual bacterium and the sublimate in the solution. The disinfecting activity of the sublimate against organisms is profoundly influenced by the proportion of albuminous material contained in the medium in which the bacteria are present. The relation between the golden pyogenic staphylococci and sublimate is not a constant one, organisms from different sources and of different ages behaving differently when exposed to the same quantity of the disinfectant, for the same length of time. The activity of the organisms that survive the exposure to the sublimate may undergo a temporary attenuation. This attenuation, however, may be caused to disappear by successive cultivation in normal media. By the method employed it was possible to select from a culture the most resistant forms in that culture. Many of the results of previous experimenters, who have assigned to corrosive sublimate more powerful disinfectant properties against the staphylococcus pyogenes aureus in cultures than the observations reported in this paper indicate, are attributable to the neglect of certain precautions now recognized as essential to the proper conduct of such experiments.

"In the light of these facts it is plain that for use in surgical practice the solutions of corrosive sublimate do not possess all the advantages hitherto attributed to them.

"There are at least two serious objections to the employment of sublimate solutions upon wound-surfaces: First, the albumin of the tissues and fluids of the body inhibits the efficacy of, or indeed renders entirely inert, the solution employed; secondly, the integrity of the tissues is materially impaired by the application of sublimate solutions. The first objection cannot be met with certainty, for the surgeon possesses no means by which he can determine the quantity of albuminous material with which his solutions are to come in contact; in any case, this large quantity of albuminous material is an almost insuperable obstacle to complete disinfection with sublimate. The second objection is equally serious. There is sufficient evidence that the normal tissues and fluids of the body possess the power of rendering inert many kinds of organisms that may have gained access. This function is therefore diminished, or, indeed, may be quite destroyed by any agent that brings about alterations in the constitution of these tissues. Just such changes are known to follow the application of sublimate solutions. If, as a result of the application of the sublimate, we bring about in these tissues a condition of superficial necrosis, they are much less able to resist the invasion of infectious organisms than they would have been had they been left in their natural condition.

"There are, perhaps, few substances that possess in a higher degree than corrosive sublimate the property of disinfection in the strict sense of the word; at the same time there is nothing employed for this purpose that requires greater care in the manipulation, in order to obtain the best results. For the foregoing reasons we seem hardly justified in continuing to give to corrosive sublimate the first place in the list of substances that may be employed practically for the purpose of rendering innocuous materials containing the germs of infectious maladies."

A ROLL OF HAIR IN THE FEMALE RECTUM.

At a meeting of one of the Polish societies, Jonszer (*Gazeta Lekarska*, 1891, 18) reported the case of a dark-haired girl, seventeen years old, in whom menstruation had been regular since the thirteenth year, who complained of griping abdominal pains and rectal tenesmus, with a moderate mucoid discharge from the rectum. The stools were at first normal in frequency, but soon there appeared obstinate diarrhea, the stools becoming very frequent (up to a score of times a day). At first they consisted of a thin, yellowish fecal matter, without particular fetor; but subsequently they assumed a whitish appearance, being composed mostly of mucus and highly offensive pus; the abdominal pain and tenesmus increased in intensity. Still later the pain became especially severe about the rectum, and there supervened frequent and refractory vomiting (of greenish, later on greenish-brown, sometimes blood-stained, fluid masses); the patient was unable to retain any food in the stomach; her general state rapidly growing from bad to worse (in spite of assiduous treatment for "dysentery," "enteritis," and like affections, by one practitioner after another). A number of months later she happened to come under the author's observation, who (apparently suspecting some intestinal obstruction near the rectum) resolved to make a digital exploration *per anum*. The examination revealed the presence of a sponge-like foreign body that could be extracted (by means of the thumb and forefinger introduced into the rectum as high up as was possible) only with considerable difficulty. It proved to be a bottle-shaped, fairly hard, felt-like mass of blonde hairs, glued together by offensive pus and mucus. The "bottle" measured eighteen centimeters in length and eight in diameter (about the base), individual hairs averaging forty centimeters. A large quantity of a fetid, muco-purulent matter welled out from the anus after the extraction, the discharge persisting for about a week. A steady, though rather slow, recovery ensued, the appetite, stools and sleep returning to the normal in about five weeks, while anemia and emaciation disappeared much later. According to the author's view of the case, the rectal hairy mass resulted from the patient having been in the habit of swallowing her own hairs. The somewhat awkward circumstance that the rectal hairs were of a color entirely different from that of the head, Dr. Jonszer is inclined to attribute to some obscure chemical influence of the gastric and other digestive juices on the swallowed hairy structures. It must be added that the girl absolutely denied having ever been in the habit of swallowing her hair.

[In an editorial note, Dr. Wladyslaw Gajkiewicz (*ibid.*, p. 349) very justly differs from Dr. Jonszer in regard to the nature of the case, and suggests the most plausible explanation, according to which the author had to deal simply with a dermoid ovarian cyst bursting into the rectum. In the same light the case is also viewed by

Dr. K. E. Wagner (see *Vratch*, 1891, No. 18, p. 450). A companion case of a hairy dermoid ovarian cyst bursting into the bladder, reported by Dr. Tchügünoff, of Shadrinsk, may be found in the *London Medical Record*, April, 1885, p. 148.] — *Provincial Medical Journal*, July 1, 1891.

HYSTERICAL STAMMERING.

KRAMER reports an interesting case of hysterical stammering in an unmarried woman, twenty-six years old. Hysterical attacks are said to have first appeared following a surprise and ill-treatment in a wood. Two years subsequently she had two convulsions, separated by an interval of a day. After the second, speech was observed to be disturbed. The disturbance took the form of aphasia; to all answers the patient replied with the single syllable "ma," repeated in rapid succession. After the aphasia had lasted a short time, stammering was observed. At first this was so marked, and the sounds were produced with such evident effort, that one could not possibly understand what was intended to be said. It was evident that the patient understood, and that only the disturbance of speech interfered with reply. This was shown by the fact that in speaking the patient repeatedly began with one syllable; at first the sounds were produced only in the larynx as short expiratory jerks developed by pressure; then they gradually assumed the sound of spoken syllables and were repeated many times; then the next syllable, then both syllables—at first imperfectly, the vowels running into one another, but subsequently becoming more distinct. When the entire word was grasped it was quickly repeated several times, as though to fix it. Having gained the first word, the second was attempted in the same way. Between the individual syllables, as they were uttered, there was a violent hiccough, or whimpering and groaning.

There was no difficulty in writing. The stammering was accompanied by a feeling as though the tongue "were of tin-plate." In fact, the patient could not thrust her tongue beyond her teeth, but moved it to and fro in the mouth, with difficulty and helplessly. Reading was attended with the same difficulty as speaking. The stammering, in its severest form, lasted from a day to a day and a half and then improved; in its milder form the stammering assumed the character observed in weeping. After about ten days the stammering disappeared entirely, to return on excitement. As is usually the case in hysterical affections, the stammering was reproduced after anesthesia with chloroform.

The reasons for regarding the stammering as hysterical are: In connection with an hysterical attack, aphasia occurred for a short time and was followed by stammering that lasted several days. Other symptoms that occurred at the same time are right-sided hemianesthesia and ovarian tenderness, contracture of the right leg, paresis of the right arm, amblyopia and concentric limitation of the fields of vision.

The stammering may be looked upon as a stage of improvement in the aphasia, just as the relaxation of the arm may be regarded as an improvement in the tetanoid spastic paresis that was present at first. As to the nature of this stammering: if mutism corresponds to total paralysis of all the organs concerned in phonation, then in stammering there must be an incoördination in the movements of these organs. As a matter of fact, Ballet and Tissier report having seen variously modified disturbances of motility of the tongue, and in Kramer's case they were also present.—*Prager med. Wochenschrift*, 1891, No. 14.

A CASE OF TIC CONVULSIF.

STEMBO (*Berliner klin. Wochenschrift*, July 13, 1891) has reported the case of a man, thirty-seven years old, with a history of masturbation, in whom at sixteen twitching was observed in the muscles of the neck, which progressively invaded the muscles of the face, of the extremities, of articulation, and the diaphragm. The movements of the tongue occasioned abnormal sounds. From time to time the chin was elevated and the head turned to the left; the upper extremity was extended. At intervals the patient would tap with the palm of his hand the person of one with whom he was speaking. At other times he would stroke the side of the protruded tongue with the index and middle finger of the left hand and then dry the moistened fingers on the head or neck. The manifestations were less decided upon the right side. They were aggravated by observation, ceased during sleep and could be temporarily suppressed by a strong effort. On the street, the patient felt impelled to hurry until he had passed all pedestrians. As he passed or met one he uttered a peculiar expiratory sound. He repeated spoken words, especially bad language. Sensibility was unimpaired. The superficial reflexes were normal. The deep reflexes were exaggerated. The neuro-muscular irritability was heightened. There were no evidences of hysteria. A son of the patient, sixteen years old, presented incipient evidences of the same affection.

PERITONEAL SECTION.

BYFORD (*Transactions Gynecological Society of Chicago*, April 17, 1891) has reported a third series of peritoneal sections, with a comparative study of 159 consecutive cases.

Nature of operation.	Operations.	Recovered.	Died.	Percentage of recoveries.	Percentage of deaths.
Hysterectomy	10	9	1	90	10
Oöphorectomy	16	16	0	100	
Ovariotomy	11	10	1	90.91	9.09

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to The Medical News will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 Walnut Street,
Philadelphia.

Subscription Price, Including Postage in North America.

Per Annum, in Advance . . . . . $4.00.
Single Copies . . . . . 10 cents.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 Sansom Street,
Philadelphia.

SATURDAY, AUGUST 22, 1891.

THE SPELLING OF MEDICAL WORDS.

Early or late every educated and clear-headed man comes face to face with the duty of deciding how he shall spell words that may rightly be spelled in two ways. Most of us shirk the duty, and drift without definite rules or principles, our orthography being almost as illogical and variable as if we had lived three hundred years ago. If, in this condition of mind, one is called as editor to make "a rule of the office" as regards disputed spellings, he may either hide himself behind the breastwork of some one lexicographer to the exclusion of all others, or he may "face the music," and endeavor to determine rules founded upon other principles than those of simple authority chosen by an eye with extreme concentric limitation of the field of vision.

It will not do to say that all this is a matter of no consequence, too trivial to waste thought upon; because, as all educated men know, that would be manifest superficiality and error.

The question of the spelling of medical English is at last, of course, one with the question of the spelling of English generally, and the rules of the special department must be consonant with the laws of the whole language. It is, however, strange that medical lexicographers have shown themselves somewhat indifferent to the trend of general American usage, and that men so busy and independent as physicians still adhere to tedious usages that in great part have been discarded by their philologically more progressive brethren of the lay world.

The conservative mind, scorning innovation, may sneer at changes in orthographic customs, but in a final analysis the most abject philological tory is without a foot of logical ground whereon to plant his feet. Language may be likened to a bicycle that is in a condition of unstable equilibrium, and must move continually if it keep upright. The very language we speak and write is itself different from the language out of which it sprang, simply by the repeated superpositions of changes in pronunciation. It is utter nonsense to think of seizing upon any one moment or phase and saying that here change must stop. The pronounced language is a living, ever-changing, ever-reacting organism. It is the materialized exponent of man's spirit, and, like that spirit, ever becoming other. Change is its most fundamental law. The dead or printed language, which is the representative of the pronounced language, must sooner or later be changed to conform to the living. Thus new dialects and new languages come into being, and thus repeated orthographic changes are constantly necessary. The fetish-worshipper of old orthography can go but a very little way back. He has accepted the changes that were wrought in his language a hundred years ago, but refuses the changes that were made twenty-five years ago and will refuse those that will be made in the next twenty-five years. He no longer writes *colic*, *physic* and *music* with a *k* after the *c*, but he sticks to it that *hemorrhage* and *etiology* and *anesthetic* must be written in the ancient way. His son will accept the shorter way of writing these words that his father spurned, but the son will also resist the reformers of his day as his father is now struggling against the reformers of our day.

Into the vexed question of general phonetic reform we have here no call to enter. There is nobody that does not recognize the ludicrous absurdity of English orthography and the burdens and clogs it imposes on the young mind and hence upon all progress. The fundamental evil and misery consists in the fact that according to current orthography, we have dozens of symbols for one sound and dozens of sounds for one symbol. That the sound of long *e* should be expressed by as many as nine signs is unendurable (*e.g.*, *meet*, *mete*, *meat*, *machine*, *grief*, *receive*, *key*, *people*, *ægis*). All the prominent philologists of America and of Great Britain are agreed

about the evil, and are practically in accord as to the remedy. They say that when etymological considerations do not prevent, all letters useless in pronunciation should be dropped. But this is positive innovation, and the world will accept it slowly. Our especial problem is not to effect desirable novelties in reform, but to choose between changes that have been introduced and that are in various stages of the process of acceptance. It would appear that the principles that should guide us are simple and at the same time fundamental:

1. When the proposed change has acquired a genuine and respectable vogue it should be held worthy of consideration;

2. If it is in conformity with the actual pronunciation, and the drift of tendency;

3. If it does not interfere with etymological considerations;

4. If it lessens labor, friction, and the space required.

5. If inevitable.

As to the first point, it is incontrovertible that the changes advised, or even permitted, by such unexceptionable authorities as the new WEBSTER and the CENTURY dictionaries, must rest on the firmest basis of philological wisdom and of commendable custom. No greater amount of money (with the risks and responsibilities for error that this implies) has ever been invested in such undertakings, and a no more splendid union of philological authorities has ever been enlisted in the preparation of such works.

As to the last point, the certainty of coming changes, it alone might be held decisive. Most of the new spellings advised at the conclusion of this editorial seem absolutely inevitable. If so, why prolong the transitional period? When the genius of our people demands these changes it were best to accept them quickly without shuffling delay and irrational prejudice. We all know the kind-hearted lady who could not bear to plunge her lobsters into boiling water, and was happy in first putting them into cold water which was then brought very, very slowly to the boiling-point.

The greatest bone of contention between the progressists and the conservatives consists in the English equivalent of the Greek αι. Shall we say *hæmorrhage*, and *anæmia*, and *ætiology*, or shall we say *hemorrhage*, *anemia*, *etiology*, etc.? Our belief is that the latter spelling, if not already the more customary, is bound to become so.

A genuine native-born American has an instinctive dislike of an Umlaut, or a conjoined vowel-diphthong. He looks askance at it, very much as a "cow-boy" does at a "dude." The shorter spelling lessens labor and mental friction, is not an etymological sin,[1] and is representative of the common pronunciation. If this position be assented to, it needs no further excuse and explanation of reasons to justify as right and commendable the following rules which have been adopted by the staff and proof-readers of THE MEDICAL NEWS:

1. The English equivalent of the Greek αι (as in αιμα, αισθητος, παιδος, etc.) will be *e*, instead of the elder form *æ*. For example:

Hemorrhage,	Anemia,
Hematemesis,	Uremia,
Hematic,	Hyperemia,
Hematin,	Hydremia,
Hematoma,	Leucocythemia,
Hematuria,	Pyemia,
Hemoglobin,	Septicemia,
Hemorrhoids,	Sapremia,
etc., etc.	*etc., etc.*
Esthesia,	Etiology,
Anesthesia,	
Hyperesthesia,	Orthopedic,
Anesthetic,	Pediatric,
Gynecology,	Ether.

2. The Greek οι will be represented by *e*, instead of *æ*. *E. g.*:

Edema,	Blenorrhea,
Esophagus,	Gonorrhea,
Celiac,	Spermatorrhea,
Cecum,	Otorrhea,
Homeopathy,	Apnea,
	Dyspnea,
	Orthopnea.

3. Liter, Center, Meter, Fiber, *etc.*, will be so written. (Chancre is correct—for a special reason.)

4. Gram, Previa, Precordia, Fetus, Fetor, Fetid, Licorice, Dram, Labor, Rigor, Color, Gluteus, Gluteal, Ozena, Rachitis, Rachialgia, *etc.*, are here properly written.

5. Leucomaïne and Ptomaïne should be written with the dieresis.

6. Unless we are brave enough to do without authorities, we shall have to submit somewhat longer to Cæsarean, Rhythm, Nævus, Frambœsia, Amœba and Pharmacopœia.

[1] In medical words there is generally no true etymology. They did not grow out of the Greek, but the Greek words were seized upon to serve as symbols and aids in forming new words, as it were with malice prepense, and often with a laughable ignorance of or indifference to the roots and laws of word-formation. Moreover, in these days of printing and detailed history, etymology is not so stern a schoolmistress as in former times.

THE ADDRESS IN MEDICINE BEFORE THE BRITISH MEDICAL ASSOCIATION.

Lauder Brunton is one of those rare men in medicine whose writings are valuable not only for the information imparted, but even more for the stimulus given to the reader's thought. A careful investigator and an independent thinker, he throws out, apparently at random, now and again, hints that, followed up, may lead to important advances in theory and practice. Thus, his speculations as to the relations of wave-interference with the chemico-vital processes concerned in the action of toxic and therapeutic agents contain, beyond question, profound truths. In his address at the recent meeting of the British Medical Association at Bournemouth, an abstract of which appeared in The Medical News for August 8th, and which is published in full in the *British Medical Journal* for August 1, 1891, Dr. Brunton has advanced, without undue insistence, a plausible explanation of a portion of the beneficial influence of blisters. This theory deserves more than passing mention, for it involves much more than its immediate context implies. Referring to the observation of Hankin that a mouse that, after being inoculated with anthrax, has a few drops of rat's serum injected into it becomes as resistant to the poison as is the rat, Brunton suggests that the application of blisters may be "a form of endermic administration of proteid matters, derived in part from the blood, but altered in their passage from the vessels to the surface of the skin, and thus having an effect on the body entirely different from what they would have had if they remained in their ordinary place."

Magnant (*Bull. Gén. de Thérap.*, May 15, 1891) has perhaps anticipated Brunton in this idea, for he treated tuberculous and other patients (varicose ulcer, diabetic ulcer, enlarged cervical gland) with injections of the serum obtained by blistering healthy persons. But the hint is worth serious investigation. We know comparatively much of bacteria, comparatively little of the physical, chemic, vital conditions of the invaded organism, which render the invasion of bacteria harmless or harmful, as may be. The thought is suggested that we may learn so to modify the vital processes as to produce and maintain in all persons the immunity undoubtedly possessed by some. Whether or not Brunton's speculation as to blisters be well founded, the greater research it implies might well be undertaken, and by none so well as the great teacher of pharmacology himself.

Dr. Brunton is right beyond question when he says that those who used bleeding in former times "were not fools." Their theory was that by depleting the circulation they could mechanically overcome stasis, lessen the heart's labor, and remove from the system "unhealthy humors." The Bournemouth lecturer says: "Experiments upon animals have shown that withdrawal of blood from the veins causes absorption of proteid matters from the tissues and these may have an action of their own upon the blood and tissues generally with which they are thus brought into contact. Indeed, it is possible that the benefits of free purgation may be partly due to a similar action." This language may a hundred years (or less) hence seem as barbarous as that of past centuries does to some of the ultra-scientific sciolists of to-day. But the important fact remains that, explained or unexplained, or but partially explained, useful measures like blistering and bleeding are not to be consigned to the limbo of delusions, because fashion and unthought abused them in the past, or because unthought sets the fashion of decrying them in the present.

A significant feature in the retrospect of "Twenty-five Years of Medical Progress," as portrayed by Dr. Brunton, is the great influence of what he terms "Darwinism" upon medicine. The new biology has made itself felt in anatomy and physiology, but less than it should have done, we fear, in pathology and therapeutics.

We confess, however, to as much surprise at reading the name of Darwin where that of Spencer should have been, as the lecturer's friend experienced in 1866 at finding him ignorant of the existence of *The Origin of Species*. Great indeed was the work, merit, and influence of Darwin—and part of Dr. Brunton's tribute to that noble character is appropriately paid; but the "doctrine of evolution" in its modern form and its application for good or for ill to the study of "the evolution of the elements, of the planetary systems, of living beings, of communities, of customs, of laws, of literature, science and art," are Spencer's. Darwin cultivated—wondrously well—but a limited portion of the vast field of thought rediscovered and largely prepared for the philosophic husbandmen of all time by Spencer. But the finished character of Darwin's work when he brought it to public atten-

tion, and his fearless extension to man of the principles applied to other animals, have largely identified his name in popular parlance with the broader principles laid down by SPENCER.

If medical men would read, more than they do, the works of these two great thinkers; if they would emulate the painstaking, accurate observation of the one, and strive to attain the comprehensive view of relations between facts exhibited by the other; they would not only be better physicians, but they would also more nearly resemble their predecessors, by whom, in a time of widespread ignorance and superstition, the learning of Nature was sacredly treasured, and the love of knowledge preserved from extinction.

PERVERTED CHARITY.

PHILADELPHIA may well be proud of her numerous charities, in the work of which her hospitals take no small part, but it must be a peculiar charity that dismisses from its care patients in the case of whom there can unfortunately be no hope of recovery. That patients suffering with chronic, incurable diseases should be excluded from institutions maintained by private resources might not be ground for criticism, but it does seem criminal that, from one motive or another, patients should be sent out of hospitals in the case of whom, once admitted, the improbability of recovery should become manifest. It is a legitimate and laudable ambition on the part of any hospital to reduce its mortality-rate to the lowest degree, but, apart from all material considerations, the dismissal of dying patients, with this end in view, cannot be too strongly condemned. A purer, sweeter, nobler charity cannot be conceived than the care of the hopelessly ill.

The sketch that we have made is not taken from an hypothetical case, but from a living picture, in colors that cannot be too vividly reproduced. Nor is the instance an isolated one. It can be no secret that cases hopelessly chronic are transferred from general hospitals to the city hospital.

The hospital is a much-abused institution. To its credit be it said, however, that if it err it is usually on the side of safety, so that whenever doubt arises it inures to the benefit of the patient; but for some reason that does not admit of ready explanation there occasionally transpires such an occurrence as is here recorded. It were far better that a hundred doubtful cases be admitted to the hospital than that by dismissal a single life be hurried out of existence.

REVIEWS.

EINFÜHRUNG IN DAS STUDIUM DER BAKTERIOLOGIE, MIT BESONDERER BERÜCKSICHTIGUNG DER MIKROSKOPISCHEN TECHNIK. FÜR AERZTE UND STUDIRENDE. Bearbeitet von DR. MED. CARL GÜNTHER, in Berlin. Zweite, vermehrte und verbesserte Auflage. Mit 72 fast sämmtlich nach eigenen Präparaten vom Verfasser hergestellten Photogrammen. Leipzig: Georg Thieme, 1891.

INTRODUCTION TO THE STUDY OF BACTERIOLOGY, WITH ESPECIAL REFERENCE TO MICROSCOPICAL TECHNIQUE. FOR PHYSICIANS AND STUDENTS. By CARL GÜNTHER, M.D., of Berlin. Second, enlarged and improved edition. With 72 photo-micrographs prepared almost exclusively from personal specimens.

BOOKS on the technique of microscopy and upon bacteriology have multiplied within the last half-dozen years until their number is legion. The department of clinical medicine represented by microscopical investigation received a powerful impetus with the birth of the science of bacteriology. Who can compare the optical instruments of to-day with those of ten years ago and not be moved with admiration at the wonderful advances that have been made? Then it would have been thought chimerical to have proposed a microscope that by the mere substitution of an ocular, could furnish with the same readiness and clearness of definition a magnification of fifteen hundred diameters and one of a hundred; that these enlargements could be reproduced and permanently recorded for illustration; and further, that by means of special apparatus magnifications of thirty or forty thousand or more could be projected upon a screen for demonstration.

The first edition of Günther's *Bacteriology* was exhausted in eight months. This, the second, in a terse and agreeable manner records the essentials of a study introductory to the subject of bacteriology, calculated to be useful alike to the student and to the general practitioner who does not contemplate more than a general acquaintance with the subject, adapted to his purposes as a clinician.

What a tribute to the father of modern bacteriology that scarcely a page but contains the name of the immortal Koch or of his pupils. Due credit, however, is not withheld from his distinguished confrères, Pasteur, Flügge, Hueppe, Löffler and others, as well as to Leuwenhoek, Cohn, de Bary and others.

Speaking of cover-glass preparations, Günther says that these may be disinfected, prior to staining, by preservation for a variable period in a solution of sublimate (sublimate 1, hydrochloric acid 5, water 1000), in which they may remain for an hour without diminution of staining affinity. In a note he adds that although the anilin-stains have decided anti-bacterial activity, all bacteria are not destroyed by saturation with the stain.

The method of staining tubercle bacilli in cover-glass preparations that he uses by preference, consists in staining in the usual way with anilin-oil fuchsin and decolorizing with a 3 per cent. solution of hydrochloric acid in alcohol; then after staining with methylene-blue and drying he passes the preparation three times through the

flame of a Bunsen burner. By this last procedure he fixes the stain permanently. We should fear lest other than tubercle bacilli remain stained or all be decolorized. Günther makes the point that *pure* alcoholic solutions of basic anilin stains are incapable of staining, and that *absolute* alcohol will not decolorize bacteria as well as animal tissues.

In the study of stained preparations he insists upon what he terms "maximum illumination," *i. e.*, the adjustment of the mirror (always plane), and of the condenser so that the apex of the cone of reflected light corresponds to the centre of the field at the plane of the preparation.

At the end of the work are seventy-two on the whole excellent photograms of the more common varieties of microörganisms.

The typography and execution of the book are excellent.

ELECTRICITY: ITS APPLICATION IN MEDICINE. By WELLINGTON ADAMS, M.D. Vol. I., pp. 105. Detroit: George S. Davis, 1891.

SHOULD the second part of Dr. Adams's admirable little book be as original, comprehensive, and practical as this, the first volume, it will when completed out-rank any of its size on a similar topic that has appeared. There seems no reason to doubt that Dr. Adams will disappoint us. He is practically conversant with general electrical science, and is, moreover, an original thinker and experimenter. His authoritative style—a striking feature of the book—may well be pardoned, in view of his evident grasp of the physical side of the subject, which he handles in a manner to excite admiration. We feel bound to express mild surprise that he should class the Barrett milli-ammeter—an instrument that, like the Barrett silver-chloride galvanic and faradic battery, though handsome in appearance, has proved in our hands utterly untrustworthy—second to his modification of the excellent Weston ammeter. It is the more curious, since he rightly characterizes the Barrett milli-ammeter as neither accurate nor reliable. The Weston, we understand, is quite as he describes it: "The first absolutely correct, direct-reading *dead-beat* milli-ammeter that has ever been placed upon the market." Dr. Adams is evidently unacquainted with Flemming's instrument, which takes high rank for reliability and accuracy. Though not technically "dead-beat," it is sufficiently so for practical purposes, and is in every way incomparably superior to the meter of Barrett.

VACATION TIME, WITH HINTS OF SUMMER LIVING. By H. S. DRAYTON, M.D. "The Science and Health Library." New York: Fowler & Wells Co., 1891.

IN a brochure of eighty-four pages, Dr. Drayton has succeeded in presenting in popular form a number of practical suggestions as to the best means of spending the summer season most advantageously.

Dr. Klaussner has been selected as the successor of Dr. Angerer as Professor Extraordinary of Surgery and as chief of the Surgical Polyclinic at the University of Munich.

CORRESPONDENCE.

BERLIN.

Latin Inscriptions — Obstetrical Cases — Gynecological Operations — Martin — Gusserow — Olshausen — Facilities for Instruction — Incentives for Work — Rupture of the Uterus — Axis-traction vs. Podalic Version — Lysol — Obstetrical Abandonment of Corrosive Sublimate — Details of an Abdominal Operation — Operation for Ectopic Gestation — Ungrateful Criticism — Martin's Clinic — His Dexterity.

ON the wall of a large building near that in which I am staying, there is a great sun-dial, having above it the inscription in large letters: *Horas non numero nisi serenas.* By the way, one very much more unexpectedly and frequently meets with Latin inscriptions in Europe than in the United States For example, one may read upon the door of an old stable in Reichenhall this probably very appropriate legend: *Cave canem.*

The seventeen days that I have spent in Berlin may be recorded as very bright days, so far as seeing some important cases in obstetrics and witnessing many gynecological operations are concerned. The latter include twenty-three laparotomies, in two of which the uterus was removed on account of myoma, two vaginal extirpations of the cancerous uterus, one operation each for vesico-vaginal fistula and for elephantiasis of the labia majora, and some sixty colporrhaphies, and operations upon the cervix and upon the perineum. The operators were Dr. Martin and Professors Olshausen and Gusserow.

Drs. Olshausen and Gusserow are professors in the University, and each has under his control for obstetric and gynecological cases, the former at the Charité and the latter at the Frauen Klinik, not less than one hundred and thirty beds; moreover, there is an external obstetrical service belonging to each, but under the immediate direction of their respective assistants. In all, more than four thousand cases of labor are available for the instruction of the medical students of the University of Berlin. Students may select the course of Gusserow or of Olshausen, and the division is about equal—each of these teachers has somewhat more than two hundred students. Professor Olshausen came here from Halle as the successor of the lamented Schröder, and being in charge of the Frauen Klinik (the buildings and appointments of which are recent and admirable, and include a residence) holds probably the most desirable public position in obstetrics and diseases of women in Germany. When I contrast the facilities for instruction here, the ample clinical material, the imperial position of teachers—no interference from ignorance, malevolence or covetousness—the great opportunity for work, and the incentive to the best work, with the condition of things in many American medical institutions, it brings a sorrow too great for words. My belief is that much greater facilities for clinical instruction, especially in obstetrics and gynecology, ought to be supplied in our great centers of medical teaching. To this end, both State and city appropriation of money ought to be made, first to those hospitals in which such instruction is given, and especially to the hospitals connected with medical schools; private institutions should be sustained by

private beneficence, or by their projectors, who established them mainly or solely for their personal advantage.

But to return: Professor Olshausen showed me two cases of rupture of the uterus, the accident in both women occurring outside of the hospital. In one case the cause was hydrocephalus in the fetus; and in the other, attempted version on account of a narrowed pelvis; delivery was effected after puncture and after craniotomy, neither patient being treated by abdominal section. One of the women was almost entirely well, and the other, and more recent case, promised prompt convalescence. These cases show the error of those who insist upon laparotomy as the rule in rupture of the uterus, berating obstetric writers for not accepting this dogma, and charging them with want of progress. It is to be regretted that there is so much dogmatism in medicine, so much disposition on the part of some in the profession to assert that "this, and this only, is the right way," and to disparage the ability, the work and the reputation of another. Individual professional experience is necessarily very limited—limited in extent and in duration—and absolute conclusions drawn from it are, therefore, liable to be erroneous. I am sorry for the physician who, as his years go on, does not grow more catholic in his opinions and become more charitable in his feelings, toward those of his own guild especially.

The axis-traction forceps is scarcely used by Berlin obstetricians, they asserting that podalic version is better suited in those cases for which the various forms of this instrument have been advised.

Lysol is being quite largely tried as an obstetric antiseptic, and Dr. Gusserow tells me that his assistants have found it satisfactory, though he has not used it himself. He further states that he has abandoned corrosive sublimate, because three of his patients perished from mercurial poisoning, an equal number dying from septic disease. The general obstetric mortality of the Charité is about one per cent., or a little less; this percentage is materially increased by women already sick being brought into the hospital.

A laparotomy (for cystoma of each ovary) was the last operation I witnessed in London before coming to Berlin; it was done at the Samaritan by Mr. Bantock, who declares microbes to be nothing but "bogies," and, of course, no antiseptics were used; but a greatly different faith and practice prevail in this city! You recognize this first when you go to one of Professor Olshausen's laparotomies, clad in a sleeveless white jacket, your own coat having been taken off; or to one of Dr. Martin's: having laid aside coat and vest, and passing through a cloud of carbolic acid spray in a hall at the entrance to the operating-room (a room used exclusively for abdominal section: an apparatus for sterilizing, by dry heat, the instruments employed is a part of the furniture of the room; possibly there is a second or third, in which the dressings are sterilized), you enter Dr. Martin's room, and it looks as if there had been a mist-like rain that had fallen upon the stone floor, and upon all the scanty furniture—everything is wet, even the walls seem afflicted with hydrorrhea. Walls and floor have been washed with a solution of sodium bicarbonate, and a powerful spray-apparatus has been diffusing carbolic acid through the rooms for hours the day before the operation. Operators and their assistants wear the linen gown, robe, shirt—whatever it is called—advised by Von Bergmann, and at the Charité I have also observed one or two of the nurses wearing a linen garment. The operator and his assistants are, of course, scrupulous in the use of hot water, soap, and brush—but Tait, Bantock, and Price, and a score of others I might name, are just as careful and thorough in the use of these means; then follows washing the hands in a corrosive sublimate solution.

The patient has the bowels and bladder emptied, has a bath, the pudendum is shaved, and she is taken to an adjacent room, where the anesthetic, always chloroform, is given; next the abdominal wall is washed with soap and hot water, scrubbed, indeed, until it blushes—if not from shame, at least from irritation; then follows a thorough washing with corrosive sublimate solution, after which the patient is carried into the operating-room —at Dr. Gusserow's clinic room she is brought in quite naked, so far as body clothing is concerned, with nothing but a sheet over her. Supposing Dr. Martin the operator, immediately after the patient is placed upon the table, the chief nurse, Frau Horn, makes a further cleansing of the abdomen, by rubbing it well with lemon-juice; then follows another washing with sublimate solution. I cannot forbear pausing for a moment to say a word about this remarkable woman. She has been in Dr. Martin's employ for eleven years, and she can anticipate the wants of the operator, almost apprehend his very thought, better than any assistant, male or female, I have ever seen; no matter what is needed at a particular moment —sponge, knife, needles, scissors, silk or catgut, forceps, what not, it is always at hand—she is alike quick in thought and in action. We have a popular expression for one who shows power and success of action: "He is a major;" I cannot call Frau Horn a major, but would rather select the superlative, and say she is an *optima;* no one who has seen her prompt and intelligent work at Dr. Martin's operations will doubt the justice of the name.

Those who have been accustomed to the short abdominal incision made by Mr. Tait, will be not a little astonished, at first, at least, at seeing the long incision so commonly made in Germany. The advantage of the latter is that the opportunity of seeing is so much greater —the operator has vision as well as touch. I think, too, that in making a long incision the discovery of the linea alba is more readily made; for I have certainly seen operators with considerable experience occasionally have delay and difficulty in finding this when making a short incision, while with the long one I have never seen Martin hesitate a second. Moreover, the sutures of the abdominal wound are more readily, possibly, too, more accurately placed if this be long than if it be short. Now, if one adds these incidental advantages to the primary one that has been mentioned, it must be admitted that much may be said in favor of the German method.

Two other points in which the work of the German operators whom I have seen differs from that of Mr. Tait and his followers: The abdomen was not washed out in a single instance, nor was a drainage-tube used, though the washing out seemed to me plainly indicated in one of Professor Gusserow's cases (a tubal gestation, with

rupture into the abdominal cavity, and considerable hemorrhage), and in two of Martin's cases (a rupture of a collection of pus during enucleation of the sacs, and some hemorrhage from tearing up adhesions). It occurred to me that not only washing out could have been wisely done, but also that a drainage-tube ought to have been employed. Yet all of these patients did well. Furthermore, in no case were silk ligatures used in the abdominal cavity—catgut always; even in a case of hysterectomy by Gusserow, and in one of complete removal of a large myomatous uterus by Martin, catgut was sufficient to secure perfect hemostasis; it should be remembered that these ligatures are used freely, three or four of them, for example, in tying the pedicle of an ovarian tumor.

From what I have seen of the work of other great operators, and from what I have seen here, I am more than ever convinced that there is more than one way to Rome—indeed, one might almost adopt a poet's line: "The ways they are many, the end it is one." The time for dogmatism has passed, and he who swears according to the method of this or that master may go widely astray, so far as justice is concerned; a true eclecticism is the wiser creed.

Among the very interesting operations performed by Professor Olshausen was one for ectopic gestation, in which the cyst had ruptured between the folds of the broad ligament, an extra-peritoneal hematocele had resulted, and suppuration had followed. Puncture of the hematocele through the vagina was first made at two points, and nothing but pure blood could be extracted by the aspirator; then an abdominal incision was made, not entering the peritoneal cavity, and a large quantity of sero-purulent and bloody fluid removed; drainage was accomplished by means of iodoform gauze. In this case the temperature, which had been elevated for some days, became normal, and when I saw her some days after the operation, her convalescence seemed assured.

It would be ungracious to make any criticism of these operations and of their methods, even if good occasion offered. He to whom the privilege of witnessing operations has been offered, would be deficient both in conscience and in courtesy did he in printed or uttered words condemn the operator who had kindly given the invitation. If the operation was wrong, he could be told so in private, and thus the endeavor be made to set him right, instead of the utterance of heedless and harsh words to others. But very often this professional critic has not the knowledge justifying his assumed rôle, and his speech may be far from silvern; it may be brazen; and his silence, above that of any other, would be golden. I know that Mr. Tait, for example, has had unjust charges made against him by men who have solicited, and have been granted, the opportunity of witnessing his operations, for I have heard them; even since I have been abroad this summer, an American physician made a statement in my presence as to Dr. Tait's want of cleanliness in abdominal operations, the former having recently seen Tait operate, that is so directly opposite to what I have myself seen that I discredit the assertion. But, even if it were true, the propriety of making it is doubtful, and beside, to receive a benefit and then attempt to injure the benefactor, does not exalt human nature.

While Professors Olshausen and Gusserow occupy important public positions, Dr. Martin has made his own position, has his own private hospital and dispensary, and gives instruction in obstetrics and diseases of women to graduates in medicine as a privat-docent. There is a daily attendance at the dispensary of from thirty to sixty patients, and the hospital, which has forty beds, always seems to be full. Probably the majority of his patients pay for their hospital accommodations, yet frequently some of them can pay but little, possibly some others nothing. His benevolence certainly must be greatly taxed. Of his ability as an operator it is not necessary to speak. He has a corps of able assistants, the first of whom is Dr. Mackenroth, who is associated with Martin in teaching, and to whom I am indebted for important acts of kindness. Though Dr. Martin is one of the most rapid of operators, he dictates to an assistant, who has tablet and pencil ready, brief statements of conditions revealed in the course of the operation. The following record made by one of his assistants tells the story of the rapidity of operating better than any general statement can:

(July 18, 1891.)

1. Frl. B., 22 years old. Tumor tubo-ovar. sin. Ovario-salp. sin. Punctio ovari. dextr. 6 min.
2. Frau K., 24 years old. Tumor tubo-ovar. dexter. Ovario-salp. dextr. 8 min.
3. Frau K., 30 years old. Tumor tubo-ovar. dexter. Salpingotom. dextr. 7 min.
4. Frl. B., 27 years old. Tumor tubo-ovar. sin. Ovario-salp. sin. Resectio ovar. dextr. 10 min.
5. Frau W., 26 years old. Tumor tubo-ovar. sin. Ovario-salp. sin. 6 min.
6. Frau S., 41 years old. Tumor tubo-ovar. dupl. Ovario-salp. dupl. 15 min.

All of these operations were accomplished and the patients were returned to their beds within two hours. Velpeau said that he credited the *vagitus uterinus* because reputable observers asserted that they had heard it, but if he heard it himself he would not believe it. So I would hardly trust my own observation as to the rapidity with which the work was accomplished—would be disposed to discredit my eyes and my watch—but I cannot doubt the statements of other observers.

I saw these patients on the fifth day subsequently, and they were all doing well. One might think that after such tax upon brain, and conscience, and hand, the operator would be very weary, and be imperatively in need of rest. But no; for Dr. Martin, after laying aside his operating attire—white flannel shirt and pantaloons and rubber apron—and resuming his usual attire, save a coat, immediately performed three plastic operations—vaginal, perineal, and uterine. A distinguished British statesman said of Daniel Webster that he was a steam-engine in breeches; and I think a similar statement might be made as to Martin.

I must not omit to mention that during the introduction of the suture for closing the abdominal wound Dr. Martin has a large flat sponge, which has been well covered with pure sweet oil, placed upon the omentum and intestines; he states that since following this plan subsequent adhesions to the abdominal wall do not occur.

The operating-rooms are small, especially that devoted to laparotomy, and, of course, the number who can witness an operation satisfactorily must be small. Those

who are fortunate enough to be invited represent many countries, and not Germany alone; I have at different times seen several from the United States, among them two prominent homeopathic practitioners from Boston, and one from Chicago, an Italian, Russians, Danes, Norwegians, and others, some of them men of great celebrity. There is danger of Martin being overrun by visitors. Indeed he tells me that he is frequently annoyed by persons whom he does not know. Possibly he may one day be compelled to institute a quarantine against visiting operators almost as strict as that which Mr. Tait is said to enforce.

Professor Olshausen usually operates at 7.30, sometimes at 7 A.M., Professor Gusserow at 8.30, and Dr. Martin at 12.

NEWS ITEMS.

Obituary.—The death is announced of DR. RICHARD LEA MACDONNELL, of Montreal, Professor of Clinical Medicine at McGill University, and Assistant Physician to the Grand Trunk Railway Company. He was the son of an eminent Irish surgeon of the same name, one of the pioneers of medical education in Canada.

Dr. MacDonnell succumbed to phthisis, at the age of thirty-eight. For his years, he had done a great deal of medical literary work. He is familiar to the readers of THE MEDICAL NEWS through valuable articles from his pen on syphilis, typhoid fever, cirrhosis, etc., that have appeared in our columns. He had taken his B.A. at McGill before he began his medical course. He had a well-stored mind, a pleasing manner, and a fine presence. His enthusiasm for scientific medicine continued to the last—at the time of his death he was engaged on an article on fevers for Pepper's forthcoming work. He leaves a widow, but no issue.

At a special meeting of the Montreal Medico-Chirurgical Society the following resolutions were unanimously adopted:

Resolved, That this society records, with the deepest regret, its sense of the loss which it has sustained in the death of Dr. Richard Lea MacDonnell, one of its most able and efficient members, who not only took part in its debates, but by valuable papers contributed from time to time, added not a little to the progress of medical science.

Resolved, That in the opinion of this Society Dr. MacDonnell's death, at a time when his usefulness was greatest, is a loss to the medical profession of Canada, in which he took a high place as a teacher and writer and earnest scientific investigator.

——— DR. THOMAS ANDERSON RODGER, a leading surgeon of Montreal, and Chief Medical Officer of the Grand Trunk Railway, died of septic pneumonia, August 6th, at the age of forty-four years. He had had large surgical experience in railway work, and was a man of most genial disposition. He began life as a pharmacist. He leaves a widow and one son.

By a curious coincidence, within a few days the great railway corporation loses its two principal medical officers.

An Army Medical Board will be in session in New York City, N. Y., during October, 1891, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before September 15, 1891, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from which they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character and moral habits. The candidate must be between twenty-one and twenty-eight years of age, and a graduate from a regular medical college, as evidence of which his diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon-General U. S. Army, Washington, D. C.

C. SUTHERLAND,
Surgeon-General, U. S. Army.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 11 TO AUGUST 17, 1891.

BAILY, JOSEPH C., *Lieutenant-Colonel and Assistant Medical Purveyor.*—Granted one month's ordinary leave, in extension of sick-leave.

GRADY, CHARLES M., *Assistant Surgeon.*—Will, upon the final adjournment of the Army Medical Board, resume his leave of absence.

COCHRAN, JOHN J., *Assistant Surgeon.*—Died at St. Luke's Hospital, New York City, N. Y., August 5, 1891.

DE WITT, THEODORE F., *Assistant Surgeon.*—Granted sick-leave of absence for thirty days.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 15, 1891.

BAKER, J., *Passed Assistant Surgeon.*—Detached from U. S. S. "Palos," and authorized to delay reporting in the United States for six months.

SAYRE, J. S., *Passed Assistant Surgeon.*—Detached from the U. S. S. "Ranger," and ordered to the U. S. S. "Palos."

MEANS, V. C. B., *Passed Assistant Surgeon.*—Ordered to the New York Naval Hospital, September 1st.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING AUGUST 8, 1891.

PURVIANCE, GEORGE, *Surgeon.*—Detailed as Chairman of Board of Examiners, August 8, 1891.

SAWTELLE, H. W., *Surgeon.*—To proceed to Portland, Me., for special duty, August 3, 1891.

GODFREY, JOHN, *Surgeon.*—To represent the Service at the Seventh International Congress of Hygiene and Demography, July 25, 1891. Detailed as a member of Board of Examiners, August 8, 1891.

IRWIN, FAIRFAX, *Surgeon.*—Detailed as Recorder of Board of Examiners, August 8, 1891.

MEAD, F. W., *Surgeon.*—Granted leave of absence for thirty days, July 30, 1891.

CARTER, H. R., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, August 8, 1891.

CARMICHAEL, D. A., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, August 3, 1891.

PETTUS, W. J., *Passed Assistant Surgeon.*—To proceed to Wilmington, N. C., for temporary duty, July 31, 1891.

PERRY, J. C., *Assistant Surgeon.*—Granted leave of absence for twenty-seven days, July 28, 1891.

ORIGINAL ARTICLES.

PREMATURE DIAGNOSIS AND PREMATURE TREATMENT OF SYPHILIS.

BY H. C. DEMBITZ, M.D.,
LECTURER ON SKIN DISEASES, ETC., AT THE HOSPITAL OF THE COLLEGE OF MEDICINE, LOUISVILLE, KY.

IN cases of obscure nervous troubles, in which by any possibility the disease may be due to syphilis, it is customary, as the saying is, to give the patient the benefit of the doubt, and put him on mercury and the iodides. In cases in which there are symptoms evidently caused by pressure on the brain or cord, or by tumors in other viscera, specific treatment is resorted to, and this in spite of the absence of any history of syphilis, in spite of strenuous denial, and without any definite lesions being found. This may not be strictly scientific, but it is eminently proper. In such cases we are often in doubt whether we have to deal with a malignant neoplasm or with a gumma, or perhaps a specific meningitis. In the former case we have little to hope for from treatment; in the latter case there is often prospect of much improvement, if not of cure. We hope for the patient's sake that syphilis is at the bottom of the trouble. But every gumma is likely to leave some injurious cicatrix behind, and the process may be quite rapid. There is, therefore, an urgent call for treatment while we may make a diagnosis. If positive, we have but to continue the treatment begun; otherwise we have done no harm, and have but postponed a very unfavorable, probably fatal, prognosis. We begin treatment because there is immediate danger. We are helped to a definite diagnosis, and we can do no harm.

How differently we are placed in many cases of suspicious sores, in which a diagnosis of hard chancre is made, and treatment begun before the appearance of the exanthem, or even of the indolent buboes. There is no occasion for haste, and so long as there remains the least doubt treatment certainly should not be begun. The case is exactly the reverse of the one just considered. There is no immediate danger. We prevent absolute certainty in diagnosis; if mistaken, we leave a cloud hanging over our patient for life, and even if correct we lose the measure of the effect of treatment, and, as experience proves, do not moderate the future course of the disease.

It has become customary to speak of hard and soft chancres, and the general use of these terms, the former to designate the sore that is to be followed by constitutional symptoms, the latter for the local non-infecting sore, is the cause of the numerous premature diagnoses, both positive and negative, which it is generally acknowledged are so often made. A typical chancre, it is true, is hard—has a peculiar, sharply limited induration, which, as is well known, is due to an infiltration of cells about the minute bloodvessels. A chancre is, therefore, most typical in situations in which there is an abundance of loose connective tissue, and the infiltration can become considerable without choking up the circulation and causing a breaking down of the chancre, and at the same time there is such a marked contrast between the loose tissue and the hard mass, that the latter can readily be picked up between the fingers.

A chancre of the prepuce, tonsil, scrotum or lips well shows this characteristic hardness; on the glans penis, cervix and other parts where the skin is firmly bound down and there is little connective tissue, the chancre soon ulcerates, and the hardness is rarely well marked.

On the other hand, a chancroid, when typical, is an acute inflammatory ulcer; there is an inflammatory infiltration, gradually shading off into the surrounding halo and the normal skin. Yet, in some subjects, the inflammation has little acuteness, and, while on the glans the chancre may resemble a chancroid, on the prepuce or scrotum the induration of the chancroid, especially if in any way treated by caustics, may approach that which is characteristic of a chancre.

When we recollect the *chancre mixte* of Rollet, we may be much puzzled to say whether our soft sore which has been touched with nitrate of silver, and has become hard, is so as the result of treatment or of double infection. For, if the patient have received both poisons, he would of course develop a soft chancre first, and, after the period of incubation, the syphilitic virus would cause its infiltration and hardness.

There are, of course, cases in which a diagnosis of chancre can be made at the first glance, but I do not think it amiss to have recalled and reviewed some of the points that so often make a diagnosis very difficult, not to say impossible. It is certainly a commentary on the uncertainty of diagnosis from the sore alone, that such an authority as Kaposi

still finds ground to adhere to the theory of unicity.

As for the history of each case, this is, except among the most intelligent class, entirely unreliable. A sore on the penis seems to have a potent occult influence on either man's truthfulness or his memory. It is difficult to say why, for the story he tells does not always put him in a better light than the truth would. The patient's statements as to time of infection are not trustworthy, owing often to multiplied opportunities and the strange psychological fact mentioned. The consecutive or contemporaneous appearance of multiple sores is of course an important point in diagnosis, presumptive evidence in the former case of chancroid, in the latter of chancre. But I have seen cases in which several chancroids developed simultaneously, and careful treatment prevented the formation of others; while, on the other hand, chancres contemporaneous in the sense of being the result of one infection, may by the patient be observed at times several days apart, one being larger, more painful, or in a more prominent place.

It is true that by waiting for an induration of the inguinal glands much light may be gained in a week or two. Enlarged, hard glands, painless and movable, developing at both sides of the groin, above Poupart's ligament, make a diagnosis of suspicion positive. But this enlargement may be on one side, may be slight, and, not developing under the physician's observation, the significance of a slight induration of the glands of one side often leaves him in doubt.

I hold that a diagnosis of chancroid only should also be guarded. The fact of the chancroid is evidence that an erosion was present, and this same erosion may have admitted the syphilitic virus as well. I have now a case under treatment in which multiple chancroids were present for four weeks before induration set in. This was after lightly touching with nitrate of silver. Diagnosis was reserved until a week later, when both groups of inguinal glands became indurated, were freely movable and but slightly tender. At the risk of appearing to hedge, it is my custom to say: "This, so far, is a soft chancre; if no special change occurs in the sore in the next few weeks, there will be no constitutional disease." The physician can then explain that the two poisons are entirely distinct, and that, if the patient was not unfortunate enough to have picked out a companion who had both diseases, he cannot acquire both. Most patients consider this chance small, and do not worry much about it. Still, if the event transpire they will not blame their physician. This is much more satisfactory than the uncertainty of the unicists.

Can the fact be denied that many cases cannot, from the primary lesion, be diagnosticated with certainty? Are there good reasons in the majority of cases for making an immediate diagnosis? Is the patient's condition and the future course of the disease bettered by specific treatment inaugurated at once? Does he incur any new danger by awaiting the exanthem, or at least the indolent buboes? All these questions may, I think, be answered in the negative. It has often been remarked that the syphilis following chancres of the face and hands runs a more severe course than usual. This, by competent authority, has been attributed to the fact that these chancres, owing to the disfiguring effects to which they give rise, or to special danger of infection, are prematurely subjected to treatment, both local and general. This early treatment often aborts the first eruptive stage altogether, and we lose all measure of the effect of the mercurial course. But the later skin eruptions are not prevented; they tend rather to be numerous, and are deeper, with a greater tendency to suppurate. It seems to me that the first eruptions may act in the nature of a vaccination, changing the soil, so that the later syphilides are modified. When the first eruption, then, is aborted we can understand why the later one should be more severe.

Whether this be the reason or not, I believe it is rather a disadvantage than a benefit to begin general treatment at once, and therefore, even when the diagnosis of chancre is positive, I confine myself to local treatment, unless there are special and urgent reasons for pushing inunctions or internal medication. In cases in which the chancre is mild I even do without mercury in any form locally.

Believing thus, I can see no occasion for hasty diagnosis of syphilis, and still less for immediate general treatment, which prevents a rectification of a mistaken diagnosis.

"Syphilis is the best sickness—that is what I always tell you," is what Professor Kaposi, in Vienna, used to say to us when he exhibited a patient after a few weeks' treatment, showing a wonderful improvement in an apparently serious case. "Gonorrhea kills more people than syphilis," was another dictum. Syphilis is certainly insidious and deadly in some of its forms, but the public, while taught care in prevention, and due attention to a case already acquired, as well as conscientious consideration of others, should not be frightened by exaggerated accounts of the ravages of this disease. Subjects who have had, and often those who have symptoms at the time, may beget healthy children, though it is true that the greatest mortality from syphilis is *in utero*. If patients' fears were somewhat calmed they would be more willing to await developments, and the fear of a patient running off to another physician would not necessitate prompt treatment against one's better judgment.

Even when a chancre is correctly diagnosticated, general specific treatment is not in order. It has been said that mercury is to constitutional syphilis what iron is to anemia—a tonic *par excellence*. This is true when the disease is generalized, not when it is local. Here the condition for which it is so wholesome is not yet present. Mercury is a poison, and the patient is so weakened and depressed by its premature use that he is less able to bear it when it is needed. Constitutional syphilis antagonizes the mercury; the local lesion does not decrease the susceptibility. The patient, in fact, enters upon the constitutional period of the disease in an enfeebled condition.

If the diagnosis of chancre be mistaken, the mercurials are injurious, and at the same time they forever mask the diagnosis, and the patient can never feel safe. A cloud hangs over him; he fears to marry; he imagines every pimple and every ache some new manifestation of a disease he never had; he is in fact often more miserable than the man who has had his early symptoms, and has been reassured by seeing the prompt effect of proper treatment.

Another point worthy of consideration at this time is the bearing of this diagnosis on life insurance, because some companies will not take risks until after a certain number of years, and some reject altogether those who have had syphilis.

How much better then to reserve a diagnosis until it can be made with certainty. Calm the patient's anxiety and, perhaps, exaggerated fears; put him on a tonic treatment if he needs it, which will aid in the cure of the chancroid, if such it be. If a constitutional disease be about to follow, this plan will put the patient in the best possible condition to bear the disease and its treatment. It may require the aid of the dentist to put the mouth in good condition. Two or three cases may well be presented to illustrate some of the points made:

Case I.—A man, unmarried, aged twenty-two, complains of painful swelling in the groin. He says he had a chancre four or five months ago; was treated for syphilis, and sent to Hot Springs. He describes rather vaguely several sores he had on his penis. The swelling he now has in his groin is not a gland, but merely a subcutaneous abscess. There are no indurated glands in the groin or elsewhere; there is no induration or cicatrix left to indicate a chancre, and no pigmentation or other evidence of a cutaneous eruption. There is some acne, which by a vivid imagination was probably converted into a syphilitic eruption.

Just as this abscess was attributed to syphilis, any of the ills his flesh may be heir to in years to come will be attributed to that doubtful chancre, and he will again plead to be dosed with mercury and iodide.

Case II.—A man, twenty-eight years of age, was examined for life insurance by a friend of mine. The physical examination was entirely satisfactory, but the patient says he had syphilis, for which he was treated four years ago. He is now married, and has two healthy children. He never had an eruption. The doctor gives the patient's account, expressing his own doubt as to the diagnosis. The application was rejected.

An old diagnosis of syphilis is like a heart-murmur. We no longer regard a heart-murmur as proof of organic disease. Still the companies prefer to keep on the safe side.

Case III.—A patient, twenty-one years of age; has a sore on his penis, diagnosticated as chancre. There is some swelling in the right groin. Treatment begun for syphilis. No general eruption occurring, the patient becomes reckless in his excursions; he has no fears of infection, and inside of one year he has acquired a veritable hard chancre.

This case hardly requires further comment. My conclusions may be very briefly summarized:

1st. Never make a diagnosis of primary syphilis until it can be made with certainty.

2d. Never treat a case until the diagnosis is absolutely certain; and then, unless there be a very special necessity, do not begin a general mercurial course until there are signs of the disease being systemic.

In men the exanthems are very rarely missed. In women, it is true, the eruption may be very slight and be overlooked. But mucous patches about the genitals and about the mouth will almost always be found; and as women in this country seldom smoke, these patches, when following a suspicious sore, will suffice for a positive diagnosis. They, as well as the eruption on the skin, constitute an indication for general treatment.

THREE CASES OF CEREBRAL APOPLEXY, ONE CASE OF PROGRESSIVE COMA, AND ONE CASE OF RHEUMATIC MENINGITIS, FOLLOWING THE GRIP.[1]

By D. W. PRENTISS, M.D.,
of Washington, D. C.

The complications and consequences of the late epidemic, called the "grip," are so varied and so far-reaching, as well as of such a serious character, that I have thought a report of the following cases would be of interest and add something to the history of that remarkable disease.

Case I. *Grip, asthma, bronchitis, apoplexy.*—Mr. B., aged fifty-seven years, has had good health, excepting asthma, from which he has suffered for many

[1] Read before the Medical Society of the District of Columbia.

years. He gives no history of apoplexy in family. He has had repeated attacks of bronchitis complicating the asthma during the past ten years. On April 1st he was taken with chill, fever, severe headache, and pains in the back and limbs. Following this there was congestion of the lungs and bronchitis. The condition was very distressing on account of the asthma. For ten days his temperature ranged from 100° to 103°, the pulse from 76 to 96. He was greatly troubled by hemorrhoids. By April 15th he had greatly improved, and appeared to be getting well, but at this date he suddenly became paralyzed, both as to motion and sensation, on the right side, in the leg, arm and face. The paralysis came on without any apparent cause. The muscles about the eye were not paralyzed. Three or four days before, he had complained of not feeling right in his head, that he could not think properly, etc., but it was supposed to be due to the opiates taken to relieve pain and produce sleep. The intellect was greatly impaired. When spoken to, he recognized persons for the moment, but soon lapsed into a condition of apathy. Speech was almost abolished by the probable involvement of the speech-center, and by the paralysis of tongue and pharynx. This condition continued with but little change until May 3d, when he died. The immediate cause of death seemed to be a sudden increase of the effusion in the brain. Treatment consisted in purging by means of croton oil at the first, followed by laxatives to keep the bowels open; bromides were used to allay nervous excitability; ergot and nourishment were given systematically by stomach and rectum.

At first this was a clear case of "grip," with the usual symptoms of fever, headache, pains in the limbs and back of a severe character, sore-throat and cough. The bronchitis was that of the "grip," aggravated by the asthma. The cough was severe and occurred in paroxysms, and may have had something to do with the apoplexy. The urine was repeatedly examined and found normal. The suffering from the hemorrhoids seemed out of proportion to the local disease. The hemorrhoid that gave the pain was internal, and refused to be relieved by suppositories of opium and belladonna, or by cocaine locally, yielding only to hypodermatic injections of morphia. The paralysis was evidently due to cerebral hemorrhage on the left side, and, from the paralysis of the face being on the same side, was above the base of the brain. The apoplexy came on six weeks after the inception of the grip.

CASE II. *Grip, bronchitis, apoplexy.*—Mr. F., aged eighty-seven years; had apparently no predispotion to apoplexy, and was in good general health. He was a remarkably active and well-preserved man for his age, a clerk in a government office, and very seldom lost a day from his work. He was taken with the grip, April 13, 1891, accompanied by fever, headache, backache, leg-ache and cough.

He was given a fever mixture, and recovered very rapidly from his symptoms, so that I made but three visits, leaving at the last a "tonic of elixir of iron, quinine and strychnine." He was well enough to go down stairs to meals, and on April 26th he said he felt so well he would go to his office the next day. He ate his breakfast with an appetite, and then sat down to read the paper. After a while one of the members of the family spoke to him, and he did not answer. This being repeated, they went to him and found him unconscious. He was carried up-stairs, and when I saw him later in the day he was still unconscious, with stertorous breathing and complete paralysis of the right side of the body, including the face. He remained comatose until death, which occurred on May 15th. He had recovered from the grip, except the exhaustion, and the apoplexy came on two weeks later.

In this case, on account of the great age of the patient, it may be true that he would have had apoplexy if he had not had the grip, but taken in connection with other cases it is of interest.

CASE III.—Mrs. H., aged sixty-seven years; had enjoyed good general health, and had always been active. There was no known predisposition to brain trouble. She had had the "grip" a month previously to the present attack, but had not entirely recovered her strength. For several days previously to the paralysis the pulse was irregular, and there was a great deal of gas in the bowels, with griping and constipation. The morning of the attack there was dizziness and weakness of the limbs, with a feeling of exhaustion. This was May 5, 1891. She lay on the bed to rest, and at 3 o'clock P.M. on attempting to arise she found that she was unable to do so.

When I saw her some hours later I found partial paralysis of the entire right side, including the right side of the face. She could move the arm and leg, but with great difficulty. Speech was very much affected, so that it was difficult to understand her, and it tired her to try to talk.

From that date (May 5th) to this (May 27th) she has been under daily observation, without much change, except that she is now improved both as to motion of the limbs and in power of speech. At times the mind has been wandering. The treatment has consisted of calomel to move the bowels, bromide to allay nervousness, and suppositories of ergotin (0.6 each) three times a day. The calomel produced slight ptyalism and diarrhea. She is now improving in all her symptoms.

In this case, in the absence of other cause, and from experience with the previous cases, I have thought there might be an etiological relation with the prevailing epidemic. The difficulty of speech seemed to be due to two factors: 1. Aphasia from the effect of the brain lesion; and 2. The paralysis of the tongue and pharyngeal muscles.

CASE IV. *Progressive coma and death following the grip.*—Mrs. F., aged eighty years, was a well-preserved woman for her age, and, until the past three years, in fairly good health. During this

latter period she had been suffering from cerebral attacks, with slight paralyses, due apparently to congestion of the brain and effusion. These attacks were usually provoked by indigestion and constipation, and were relieved by purging and bromides. On March 22, 1891, Mrs. F. had sore-throat, fever, headache, and pains in the limbs. There was no tonsillitis. At first, and subsequently, bronchitis developed broncho-pneumonia. The cough caused great distress and loss of rest. This attack of broncho-pneumonia ran a course of ten days to resolution, but the patient, instead of rallying to recovery, fell into a stupor, from which at first she was easily roused, but day by day it gradually deepened into complete coma, and she died April 29, 1891.

In this case the coma seemed to be caused by gradual serous effusion into the brain, and was undoubtedly a direct result of the illness caused by the grip.

Case V. *Rheumatism and rheumatic meningitis following the grip.*—Miss G., about forty-five years of age, had enjoyed good general health. She had an attack of grip the latter part of March, from which she appeared to have recovered. On April 24, 1891, she was attacked with violent pains in all her joints, so that when moved or touched she screamed. There was no fever, no swelling, and no redness of the affected joints. On April 27th the temperature was 102.5°, and there was swelling, redness and pain in the finger-joints of both hands. On April 28th the fever was the same, with swelling of ankles and wrists. April 29th the thermometer registered 100.6°, and there was no relief from pain. She was at times delirious, with violent headache. From this time on the delirium increased, with retention of urine and constipation. Symptoms of meningitis were marked. On May 9th she was sent to Garfield Hospital, where she died three days later of meningitis.

I have reported these cases as following the "grip," and probably sustaining to that disease a causative relation. My reasons for this belief are:

1st. The sequence. In none of the cases was there any other apparent cause.

2d. The "grip" is a disease attended with well-marked symptoms pointing to derangement of the nerve-centers. This is shown by severe and characteristic pains which, during the acute stage, are its most pronounced symptoms, and also by the great nervous prostration that in so many cases follows. This has been universally observed, and has sometimes been extreme.

In one case, a lady forty-five years old, all her life exceptionally well and strong, had a moderately severe form of the disease, and apparently recovered. I had stopped visiting her, when a few days later she sent for me. I found her very much alarmed. She informed me that she knew she was going to die—that she could not walk across the room. I reassured her, prescribed tonics, and she ultimately recovered, but for several weeks she was not able to return to her duties as a department clerk.

One of the cases, that of rheumatic meningitis, deserves special mention. It seemed clearly due to the grip, and the symptoms, in the ordinary sense of the term, were not those of well-defined rheumatism. For several days the violent pains in the joints continued without any sign of inflammation, redness or swelling. When these did appear they were most marked in the finger-joints, hardly at all in the larger joints, although the pain continued. When the meningitis set in the joint-symptoms ceased. It seemed as if some morbid germ, or germ-product, were here at work.

A recent writer (Adenot, *New York Med. Record*, May 9, 1891) gives a list of pathological germs found in meningitis. These are the intercellular diplococcus of Weichselbaum; the pneumococcus of Fränkel; the pneumo-bacillus of Friedlander; streptococcus pyogenes; staphylococcus pyogenes; typhoid bacillus of Neumann and Schaeffer; and the pseudo typhoid bacillus of Roux.

I mention these in detail, because it seems that if so many different pathological germs are capable of causing meningitis, so also may the undiscovered germ of this epidemic malady. In Case IV., which I have called "progressive coma," there was no *apoplexy*, but evidently a gradual effusion, probably of serum, that first produced sopor, then stupor, and finally complete coma, which continued until death. All this followed immediately upon the grip. In this case also there had been previous disease of the brain.

As to the location of hemorrhage in the cases of apoplexy, it was on the left side in all three cases, and in the cerebrum or central ganglia. This was shown by the right-sided paralysis, and by the paralysis of the face being upon the same side. I have said little of treatment, because the treatment of "grip" is not under consideration, and because in the treatment of the apoplexy there was nothing out of the usual course.

There were no autopsies.

DEFECTS OF THE OCULAR MUSCLES.

By JOHN S. STEWART, M.D.,
of Philadelphia.

Affections of the ocular muscles occupy a position of no small importance in the study of the eye, its defects and diseases. Especially is this true since the relations of ocular conditions to disturbances of the nervous system and general bodily health have come to be appreciated.

A somewhat complicated system of ocular muscles adjusts the two eyes in such a manner as to

obtain *binocular* vision, the separate retinal images making but a single mental impression; but it is only when the adjustment of these muscles is perfect, and when corresponding portions of the two retinæ are thus made to receive the two images that single vision can be maintained. With every new adjustment of the eyes, either for nearer objects or for more distant ones, new movements and different degrees of tension are thrown on these muscles, and the response must be instantaneous. Such ever-changing and extremely nicely associated actions are demanded in no other part of the organism. It is, therefore, not surprising that this exacting service—when difficulties in its performance are encountered—should make excessive demands on the stock of nervous energy of the individual, or give rise to discomfort in the eyes, and even in other parts of the body.

Defects of the ocular muscles may be divided into two classes, viz.:

1. Overaction of one or more of the muscles.
2. Weakness (insufficiency), or paralysis of one or more of the muscles.

Of course, it is quite possible for these two abnormal conditions to coexist and thus exaggerate, while at the same time making more manifest, the defectiveness. The character of the symptoms manifested depends both on the degree of the defect and on the ability to overcome it by extra effort on the part of the eye-muscles. Thus, if there be only slight weakness of one muscle and but little tendency to overaction of its opponent, the eyes can be kept with their axes practically parallel. The only symptoms then may be fatigue on use of the eyes, irritation about the eyes themselves, or pain referred to various portions of the head and body. But, apart from the suffering thus occasioned, the eyes may seem strong and good, especially if the sight does not happen to be defective, so that suspicions are likely to be centered on other parts of the organism where some of the discomforts may have been manifested through reflex action of the nervous system.

The fact cannot be too strongly emphasized that slight defects of this character give rise to more suffering from the use of the eyes, to greater discomforts in other parts of the body, and to more serious disturbance of the nervous system, than do the highest degrees either of overaction or of insufficiency. This may seem strange, but the reason is not hard to find. For, when the defect is of such degree that the two eyes can no longer be kept with their axes parallel, or as nearly so as may be required for single vision, one or the other of them will be observed to deviate either inward, outward, or in a vertical direction. As a result we have some one of the forms of "squint," or *strabismus*.

One of two results must happen when the eyes can no longer be accurately directed toward the same object—either there will be double vision, or the retinal image in one eye will be suppressed. Should the first of these results happen the confusion and annoyance from seeing everything "double" will be very great; but the suppression of one image most frequently occurs, and the individual then uses only one eye at a time. Sooner or later, however, one of the eyes is likely to be called on to perform every act of vision, and the other is then in danger of becoming permanently disabled from want of use.

It must not be forgotten, however, that differences in the refraction of the two eyes often cause unconscious choice of the better organ for vision and consequent deviation, either outward or inward, of the other and less perfect one. This is likely to be the case when one eye is perfect, or nearly so, and the other is either highly hypermetropic, myopic, or astigmatic—or, when one eye is hypermetropic and the other myopic (anisometropia); when the latter anomaly exists one eye may be habitually used only for distant objects and the other only for those near by.

The intimate relation existing between the various forms of squint and the different errors of refraction is too little understood even by the intelligent and educated, and a brief consideration of the subject may be useful.

Strange as it must seem, squint is still by many ascribed to imitation, to teething, to fright, and to innumerable other conditions which can have nothing to do with it. Children have repeatedly been punished for squinting, when it would have been as reasonable and effective to punish them for having blue eyes instead of brown ones. Therefore, it cannot be too generally known that children with a certain degree of hypermetropia must squint by a necessity of their organization. It is the only means by which they can overcome the consequences of their ocular defect. On the other hand, those that have differently formed eyes have no cause or temptation to squint, and would probably be unable to do so even by any amount of carefully directed effort. About 90 per cent. of all the cases of convergent squint are directly produced by hypermetropia; yet the hypermetropic persons who squint are probably not more than two-thirds of the whole number. The rationale of this form of squint is that when a short-eyed (hypermetropic) child first begins to employ his vision carefully—at three or four years of age—it is necessary for him to exert a high degree of accommodation. This is more readily done if it is associated with convergence-effort, hence the latter becomes as habitual as the former. The *internal recti* muscles being thus continually exercised increase in strength, and it

eventually happens, by reason of their increased power and their frequent or continuous exertion, that they, like the muscles of accommodation, fall into a sort of spasm, so that the habitual and resting position of the eyes comes to be one of convergence. After a short time this convergence cannot be relaxed, and double vision of all objects must then be produced, unless one of the eyes rolls still further inward so that its image, having fallen upon a comparatively insensitive portion of the retina, may be neglected or suppressed by the brain. The intolerable inconvenience of double vision is thus generally removed by the act of squinting.

At first the eyes are usually affected alternately; but after awhile, either because one eye has better vision than the other, or because from some inequality between the muscles one is more easily rotated than the other, we see, as a rule, that one is always made the working eye and the other always the squinting eye.

The reason why some hypermetropic persons squint and others do not appears to depend mainly on the closeness or laxity of the tie between the functions of *accommodation* and *convergence*.

Divergent strabismus is much less common than the convergent variety, and is usually dependent on myopia, although it may occur in some cases of high hypermetropia or astigmatism. Very frequently it is due either to insufficiency or to paralysis of the internal recti muscles. In myopia the eyeball is elongated, and its range of movement diminished, so that the extreme convergence that is necessary to enable the patient to see objects within his range of vision tires out the inner recti muscles, and, for relief from the distress, one of them gives way, and the eye deviates outward. Sometimes the deviation takes place only after the individual has been working for some time and the eyes feel fatigued; in others it is only noticeable in looking at objects beyond the far point. Soon, however, the squint becomes continuous, and usually tends to increase. As soon as this occurs, whatever the variety of the squint, the vision of the deviating eye begins to undergo progressive impairment.

Therefore, the strabismus should be removed or overcome without delay; and it is obvious that treatment must be directed first to correction of every discoverable error of refraction, so as to bring the accommodation-effort and the convergence-effort into harmony. In the case of children in whom the squint is of low degree and has existed only a short time, the dangerous disfigurement can usually be removed by the continuous wearing of proper glasses. From the records of my own practice I judge that fully 75 per cent. of the strabismus occurring in the young can be overcome by careful measurement and correction of the refractive error. In a considerable number of the cases that I have treated with glasses alone this result has proved to be a permanent one. If the vision of the two eyes be different, that in the squinting one being more or less impaired, it is oftentimes of service to exercise the less perfect eye by itself for a certain fixed time daily, and it will usually be found that visual improvement progresses steadily until, after perhaps several months of this exercise and training, the powers of the two eyes become almost, if not altogether, equal.

But when the glasses have been worn a month or more without improvement, or when the squint is of very high degree, tenotomy must be performed, and so long as the vision of each eye is fairly good a perfect result can be expected if the glasses be worn in addition. If, on the contrary, the operation has been too long delayed until the vision of the squinting eye and the tone of its muscles have alike suffered, only a partial correction of the disfigurement can be hoped for. But for the sake of both vision and appearance every squint dependent on error of refraction, and not overcome by wearing of the proper glasses, should be subjected to operation.

Thus far our attention has been directed to defects of the ocular muscles unmistakably manifesting themselves in the eyes. But there is even a more numerous class of cases of this character in which the symptoms, in addition to being local, may manifest themselves to a considerable degree in parts of the body seemingly remote from the eyes. *Heterophoria* is the term now generally employed to describe those ocular conditions formerly very imperfectly and oftentimes quite incorrectly known as *insufficiencies*. But this class of muscular faults differs so widely from those at present under consideration that it has been thought best to give them separate consideration. Accordingly, the writer's experience in the treatment of the various forms of heterophoria will be given in another paper.

1537 Chestnut Street.

TREATMENT OF COMMON COLDS IN CHILDREN.

By HERMAN B. ALLYN, M.D.,
INSTRUCTOR IN PHYSICAL DIAGNOSIS IN THE UNIVERSITY OF PENNSYLVANIA; CHIEF OF THE DISPENSARY FOR DISEASES OF WOMEN AND CHILDREN, ST. JOSEPH'S HOSPITAL.

The affection commonly called a cold consists, in its mild form, in a congestion of the mucous membranes of the respiratory tract, attended first with an outpouring of serum and subsequently of mucus and muco-pus. The cold may be limited to any part of the respiratory tract, but the nose and naso-pharynx are the portions generally involved. Frequently the process begins in the nose or throat, but, when the patient comes under observation, the bronchial mucous membrane is most affected. The

stage of congestion is of brief duration, especially in those who are more or less subject to colds; hence, when seen by the physician, the affection consists in an acute or subacute catarrh of the mucous membranes involved.

The nature of the process, as seen in children, does not differ from that in adults. Children are, however, more prone than adults to develop bronchial catarrh, and the nasal catarrh is, in the former, more apt to become subacute and even chronic. The chief reason for the latter fact is doubtless to be found in the relative helplessness of children, who cannot cleanse their noses properly, and are often neglected by their parents. The spectacle of a neglected child of poor parents, with a disgusting muco-purulent discharge from the nose, is too common to occasion much comment. Another reason for the preponderance of these catarrhs in children is the difficulty attending treatment.

For a cold in the congestive stage, the child may be given a hot bath and then be put to bed, well wrapped in blankets, to encourage free perspiration. Veratrum viride and aconite may also be of distinct service; one or the other should be given in doses suited to the age of the patient to produce the effect desired. The atmosphere of the room need not be above 70° F., but while the mucous membranes are dry and parched a certain degree of moisture will be grateful to the little patient. This moisture can be provided by having a steaming teakettle in the room, or by keeping a pan filled with water on the stove. If there should be no stove in the room, a gas-jet may be utilized, first suspending over it on top of the shade a sheet of wire, such as is sometimes used to avoid the scorching of a table-cloth by a hot coffee-pot. The best device for use in the sick-room is a Bunsen burner made with a flat, circular top, two inches in diameter. The gas-jets are made to emerge horizontally in a radiating manner beneath this top. The whole Bunsen burner can be screwed on an ordinary bracket in place of the customary burner. On this burner a tin cup or other small vessel can be placed, and the room quickly filled with vapor, medicated or not, as desired.

In the first and second stages of a nasal catarrh, menthol is an excellent remedy. All are familiar with Cushman's menthol inhaler, which is an admirable apparatus for adults; its employment, however, cannot be made effective in the case of children; while with infants its use is out of the question. For the benefit of these little patients, therefore, I am in the habit of ordering menthol in crystals, having about a third or half of a teaspoonful placed in water and heated gently until it begins to steam. The menthol vapor is liberated very rapidly. One must regulate the quantity of menthol and water in accordance with the size of the room, especially its height, and not keep doors and windows open unless the vapor of the menthol should become too pungent. As the menthol vapor is irritating to the mucous membrane of the eye, I prefer to use it in the sleeping-room of the child at night after it is asleep.

In the second stage of acute rhinitis, benefit will be obtained from the local use of a weak solution of salt in warm water, say about a fourth of a teaspoonful of salt, or even less, to a tumbler of water. The salt-and-water solution is so soothing that children who get over the first fright at having any liquid put into the nostrils, no longer make any objection. I have found a medicine-dropper the most serviceable instrument for instilling the lotion. Thorough cleansing of the nasal passages cannot, of course, be performed in this way, but, on the other hand, there is less risk of causing an acute inflammation of the middle ear than if a syringe were used. At a later stage in the catarrhal process, the "alkaline and antiseptic" tablets, prepared according to a formula by Seiler, are better than simple salt and water. Half of one of the tablets should be crushed and then dissolved in a third of a glass of warm water. Not infrequently the resulting solution is too irritating; when this is the case a little salt should be added to it. Before the solution is introduced, the nasal passages should, as thoroughly as possible, be freed of secretion. The solution should be employed several times a day. An extemporaneous substitute for the tablets can be prepared by adding to a weak salt-water solution minute quantities of soda and borax. These are especially indicated when there is a tendency for the secretion to become thick and purulent and for crusts to form. I have found a five or ten per cent. solution of menthol in almond oil, applied to the nostrils with a pledget of cotton or a camel's-hair brush, also very helpful. The local applications, with inhalations of menthol at night, as a rule, soon effect a cure in a subacute rhinitis.

When a child is disposed to "catch cold" easily and frequently, there is often a strumous habit present, and the tonsils are often enlarged. In such cases cod-liver oil, begun in the autumn and taken until the following spring, effects a great improvement. I have seen no good results from the syrup of iodide of iron, but the syrup of hydriodic acid has seemed to do good.

As a rule, before a cold subsides, there is more or less bronchitis, from extension of the catarrhal process. Generally only the larger and middle-sized tubes are affected. Local remedies are here of great value. In infants and in very young children, a stimulating liniment containing oil of amber, camphor and oil of turpentine, with soap liniment as a

vehicle, is very serviceable. Poultices are, as a rule, not needed in mild cases of bronchitis occurring in the course of "colds." They can, however, be of great service. In using them in these cases I prefer to have them applied at night. They should be large enough to cover the entire chest, anteriorly and posteriorly. Strips of tape passed over the shoulders and fastened with safety-pins to the muslin of the poultice will aid in keeping the poultice in place. The poultices should be thin, and preferably made of flaxseed meal, with the addition of one part of good mustard to 16 or 20 parts of the flaxseed, according to the age of the child. The proportion of mustard should be small, as it is desirable that the child should sleep the entire night in one jacket-poultice.

When the flaxseed and mustard poultices are made up with glycerin and white of egg, a larger proportion of mustard can be incorporated, and the poultices can also be kept on longer, without risk of blistering the patient.

For older children, painting the chest gently in the morning with iodine once a day, until the skin becomes somewhat tender, is better than the application of liniments or poultices.

In these cases of mild bronchitis, inhalations of oil of turpentine, or, still better, oil of eucalyptus, are decidedly helpful. In the houses of the poor they can be given by keeping the patient in the kitchen and having on the stove or range an open vessel of water containing about a teaspoonful of the oil to a pint of water. It may be desirable to have the patient sleep in the kitchen at night.

Of internal remedies, nothing is better than the remedy almost universally employed—chloride of ammonium. It is best given at intervals of an hour or two, in doses appropriate to the age of the patient. When it has seemed necessary, I have sometimes induced the mother to take the chloride for the benefit of the nursing infant.

It is true that, so far as life is concerned, the majority of these cases would not terminate seriously if no treatment were employed. But it cannot be denied that in some cases a grave catarrhal pneumonia would be the ultimate result of a neglected cold, and in many others neglect to treat the case would lay the foundation for an obstinate chronic naso-pharyngeal catarrh, with all its unpleasant consequences. We cannot, therefore, afford to be indifferent to the treatment of these common colds.

310 North 40th Street.

Francis May Dickinson, M.B. Lond., has been appointed anesthetizer at the Alexandra Hospital for Children with Hip-disease, in London. She is said to be the first woman appointed to such a position in a London hospital, excepting the New Hospital for Women.

FOUR CASES OF TRUE PELVIC ABSCESS.

By CHARLES P. NOBLE, M.D.,
SURGEON-IN-CHARGE, KENSINGTON HOSPITAL FOR WOMEN, PHILADELPHIA.

During the past few years many abdominal surgeons have denied the occurrence of true pelvic abscess, or have admitted it only as a pathological curiosity. These men have permitted themselves to be blinded by their own personal experience, and have so lacked scientific spirit that they have accused other observers, equally worthy of credence, of incompetence. Because they have found pus in the pelvis only in cases of pyosalpinx, abscess of the ovary or purulent peritonitis, they have argued that true pelvic abscess—abscess in the connective tissue of the pelvis—does not occur; that, because they have found pelvic inflammation to be inflammation of the uterine appendages or peritoneum, therefore cellulitis does not occur. They have confused the relative with the absolute.

No one believes more firmly than I that the common form of pelvic inflammation is salpingitis, with peritonitis; and that when pus forms in the pelvis it is usually in the Fallopian tubes, the ovaries or within the peritoneum; yet I know that, as a *puerperal* condition, cellulitis and true pelvic abscess not rarely occur. Four cases of such abscesses have come under my notice. As a non-puerperal condition I have not seen cellulitis or true pelvic abscess, and I know of no evidence that such inflammation occurs, except after traumatism within the pelvis.

As to the relative frequency of true pelvic abscess as compared with the other varieties of accumulations of pus within the pelvis, I believe the former is rare, constituting only a small percentage of cases. I report these cases as a contribution to the subject of pelvic inflammation. In three, the evidence of their true nature is incontestable; in the fourth, it is perfectly satisfactory.

The first two cases have already been reported in full to the Philadelphia Obstetrical Society; so I shall merely refer to them. The first was operated upon by Dr. Longaker, some weeks after labor, Dr. Parish and myself assisting. The belly was opened, the tubes were found healthy, a second incision was made parallel with Poupart's ligament and a large quantity of pus was evacuated. The abscess occupied the left broad ligament and had burrowed between the uterus and bladder into the right broad ligament. Recovery followed.

The second case was operated on by Dr. Wilson, whom I assisted. The operation was similar to the first. The tubes were healthy. As the induration was in the region of the false pelvis, a second incision was made near the anterior superior spine of the ilium. A large quantity of pus was evacuated. Recovery followed.

The third case I saw in consultation with Dr. Himmelwright, March 2, 1890. The history, as given to me by Dr. Himmelwright, is as follows:

The patient had a miscarriage, January 3d, in the second month of pregnancy. One week later, symptoms of pelvic inflammation appeared, and a diagnosis of peritonitis was made. The patient got about by February 1st. After a week, pain was felt in the right inguinal region, and gradually increased in intensity, extending to the lumbar region. After another week (February 15th), she was unable to walk erect and to put her right foot firmly upon the ground, but had to stoop forward. During this time the temperature remained normal and there were no chills. At times the pulse was slightly accelerated. The pain continued to increase, and, on February 27th, a swelling was noticed in the right lumbar region. March 1st, the temperature rose to 101° F., and the pulse to 120, and there were slight chills. March 2d, I saw her. The temperature was normal, the pulse about 90. The right inguinal region was tender, suggesting, indeed, appendicitis, but there were no symptoms to warrant the supposition. A semi-fluctuant swelling was found in the right lumbar region. The next day this swelling had increased, and a hard mass was felt in the right inguinal region, extending as high as the ribs. The swelling in the lumbar region was opened and two or three pints of pus escaped. Introducing my index finger, it passed around the ilium into the iliac fossa. A rubber drainage-tube was introduced, and irrigated daily with a dilute solution of peroxide of hydrogen. For a few days large quantities of pus were discharged. The discharge gradually decreased and the tract rapidly healed—closing from the bottom.

It may be asked: "Why do I claim this as a case of true pelvic abscess?" The abscess was undoubtedly situated in the false pelvis, on the right side. I had my finger in it. The entire absence of bowel-symptoms excludes perityphlitis. The fact that, on examination, the uterus was found movable and the broad ligaments free from exudate—no fixation of the appendages—excludes pyosalpinx. Hence I take it the abscess was due to the breaking down of an infected pelvic gland situated behind the peritoneum, in the right iliac region.

The fourth case was in every way similar to the first. I saw the patient in consultation with Dr. Longaker, five weeks after labor.

The perineum had been torn and was sutured some hours after labor. Septic infection occurred, and for three weeks the temperature ranged between 100° F. and 103° F. During this time there was no pain or distention of the abdomen, or tenderness of the uterine appendages on examination. The perineal wound became inflamed, however, and the stitches were removed. During the fourth week all the symptoms abated. At the beginning of the fifth week the fever increased and tenderness in the left inguinal region became marked. Purulent matter had been discharged *per vaginam*, but whether or not it came from the abscess which had formed was questionable. On examining the patient five weeks after labor, I found her much depressed, in a typhoid condition, with a swelling above the pubes and to the left. Under chloroform, a mass of exudate was felt in the left broad ligament extending between the uterus and bladder, and plainly palpable above the pubes. My diagnosis was true pelvic abscess. I advised median section for an absolute exclusion of complicating pyosalpinx; then a second incision, parallel with Poupart's ligament, to evacuate the abscess. This was done by Dr. Longaker on the following day. The uterus, ovaries and tubes were found healthy; nor was the bladder involved. The omentum was, in places, densely adherent. The abscess was situated beneath the broad ligament and extended upward, behind and two inches above the ramus of the pubes. It contained about six ounces of thick pus, which was evacuated by an incision in the left inguinal region, directly above Poupart's ligament. As there was considerable hemorrhage, a glass drainage-tube was introduced into the median incision and a rubber tube into the lateral. The ultimate recovery was perfect.

The report of these cases simply confirms what has long been known, namely, that as a puerperal condition true pelvic abscess does occur.

CLINICAL MEMORANDUM.

THE ROLLER BANDAGE FOR THE PAINS OF TABES DORSALIS.

BY JOSEPH LEIDY, M.D.,
OF PHILADELPHIA.

THIS note is for the purpose of drawing attention to the results of a simple method for the relief of pain during the course of spinal disease, and especially tabes dorsalis.

Warmth, in the form of the warm bath, has long been recognized as of considerable utility in the treatment of this symptom.

The writer has frequently observed the relief afforded by the firm application of a roller bandage in the spasmodic and painful conditions so common in the extremities following traumatism. It occurred to him that the application of such a bandage (flannel or hose) to the part the seat of pain in locomotor ataxia might be of some service in mitigating the suffering. He found that the firm application of a bandage (flannel) from the toes to the upper third of the thigh was attended with great relief. During the past six months this method of treatment has been employed with most encouraging results. For the girdle pains a bandage, similar to the abdominal binder, firmly applied at the level of the abnormal sensations, afforded almost instant relief. The cases under observation had been treated with galvanism, with absolute rest, and the usual therapeutic measures, the majority of which had failed. The usefulness of this method depends principally upon the pressure and warmth that the bandage affords, combined with rest. It is worthy of further trial, if only as a substitute for morphia. In one case

the removal of the chest-binder was in several hours followed by a return of the girdle sensations. Two other patients invariably suffer a return of pain in the lower extremity on the removal of the bandage. In suitable cases the elastic stocking may, with advantage, be substituted for the bandage, as it does not interfere with locomotion.

The application of a roller bandage about the seat of pain was equally useful in several instances in which the area of pain was localized.

The method of treatment indicated will, I trust, commend itself for its simplicity, with the advantage of acting as a substitute for drugs.

ORIGINAL LECTURE.

THE HEART: ITS MURMURS, THEIR DIAGNOSIS AND TREATMENT, AND THE ACTION OF THE CARDIANTS AS A CLASS.[1]

By WILLIAM HENRY PORTER, M.D.,
PROFESSOR OF CLINICAL MEDICINE AND PATHOLOGY IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

LECTURE IV.

Gentlemen: At our last lecture we finished the discussion of alcohol; to-day we shall consider digitalis and some of the other drugs that are of avail in treating cardiac lesions.

Probably there is no single drug that has received so much attention as *digitalis*, and even now there is a wide difference of opinion as to its action and true therapeutic value. Much of this doubt, however, is removed, and the action of the remedy made plain by a thorough knowledge of the chemical composition of digitalis. Then, by keeping clearly in mind the physiological laws that govern the animal economy, and carefully noting the changes that take place under the influence of digitalis, much that has heretofore been vague and uncertain becomes positive, and the action of the drug sharply defined.

Another important reason for many of the incomplete and contradictory statements in connection with digitalis —in fact, with most drugs, and especially when the deductions are based upon clinical evidence—is furnished by the fact that frequently conclusions are arrived at when two or more drugs of a similar, and sometimes even of a dissimilar, character are simultaneously administered. As a natural sequence, the evidence is worthless, for under such circumstances no human mind is able to decide to which drug justly belongs the credit, nor how much the action of one drug alters or modifies that of another. The correct and sure way to develop clinical deductions of real value is to administer one drug at a time to a large number of cases of similar character, and under as nearly as possible the same conditions. Then the drug under study should be continued in increasing doses for a period long enough to make certain that the system has been fully brought under its influence, and that the physiological limit has been reached and exceeded. In this way two distinct results are obtained: the physiological action of the drug is determined, and its toxic symptoms are clearly defined. Such evidence, together with that derived from experiments upon the lower animals, and with an accurate knowledge of the physiological laws of the body, enables us to obtain results almost absolute in nature. Such knowledge permits us to say exactly what can be accomplished by the internal administration of a single drug under given circumstances, and raises therapeutics from empiricism to an exact science.

After learning the actions of individual drugs, we have a rational basis upon which to combine to advantage in a single formula two or more remedies; thus intelligently united, they can often be administered with great benefit to the patient.

On this point I have always with profit remembered the teaching of Professor Edward Curtis, which practically was: "Never make a general contribution-box or postoffice of a patient's stomach by turning into it all the drugs at hand, hoping, perchance, to satisfactorily combat his ills with some of the agents used, but, rather, first accurately learn the physiological actions of the drugs to be administered; then give them with a definite and fixed purpose, and if the desired effect is not forthcoming, find out the trouble with the physiological mechanism of the patient, and do not condemn the drugs wholesale because the expected result was not at once obtained." It has always seemed to me that if we only more closely followed this admirable rule in using old and common drugs until thoroughly familiar with their full powers, rather than to rush madly after new and untried remedies, hoping in or through them to find specifics with which to combat complex and multitudinous abnormal physiological problems, our efforts would be better rewarded in the much more exact and satisfactory results obtained for our patients.

But let us return to the composition of digitalis. By reference to our table of cardiants,[1] we find that digitalis is quite a complex body, containing chemically five substances, four of which have been formulated. You further notice that these substances are composed of the elements carbon, hydrogen and oxygen, combined in varying atomic proportions. Most of them are classed as glucosides, because by boiling with acids or other agents they can be made to take up a molecule of water and be converted into glucose. Within the system it is quite probable that they are oxidized, forming compounds or by-products resembling alcohol, and are finally converted into and eliminated from the system as carbon dioxide and water. While passing through this transitional process, they evolve heat and energy, and stimulate the nervous mechanism and functions of the body with varying degrees of intensity.

Drugs of this chemical composition, as well as foodstuffs of an analogous nature, are best called CHO compounds, for by using this term no confusion can arise as to the character of the substance administered, and the chemical elements entering into its constitution are sharply defined, even though the exact atomicity of the drug is not given.

You will remember that in studying digestion and assimilation, and the results obtained by the use of alcohol, it was shown that there is a common tendency on the part of the physiological economy in dealing with

[1] A series of lectures delivered at the New York Post-Graduate Medical School and Hospital.

[1] The Medical News, July 25, 1891, p. 99.

these CHO substances to oxidize or split them up into compounds or by-products resembling alcohol, if that had not already been accomplished outside the body, as is the case when starch and sugar are first converted into alcohol before being introduced into the system, and ultimately to transform them into the final or excrementitious products—carbon dioxide and water. In some instances this result is quickly accomplished, while in others a considerable lapse of time may intervene before the bodies are completely changed. In all instances, however, while they are passing through this cycle of transformation to reach the final products to be eliminated by the excretory organs, they are continuously evolving heat and energy. This development of heat and energy and the consequent results, in some way stimulate the nervous system, and through it the functions of the body are excited to greater activity, or depressed below the normal standard. Whether these changes are due directly to the action of a specific drug *per se*, or result from a disturbance in the general body-oxidization and the development out of the proteid bodies of various intermediate nitrogenous compounds, has not as yet been fully made out by the physiological chemist. In the case of digitalis, however, the latter factor seems to be sustained, for when digitalis is administered in full doses, the proportion of uric acid in the urine is augmented, while the percentage of urea often falls, an evidence that there is a marked tendency on the part of the system, when under the influence of the drug, to imperfectly oxidize proteids. The diminished excretion of urea could be explained by the increased rapidity of the renal circulation, but in such a case the excretion of uric acid ought also to be diminished; but as this is not the fact, the condition must be dependent upon disturbed oxidization.

In diseased conditions, stimulation by digitalis, within physiological limits or temporarily, may be of service to the animal economy, in the same way as is alcohol, by calling into action the reserve force of the system. If, at the same time that this increased vital activity is developed, the requisite quantity of proteids can be digested and assimilated to fully compensate for this excessive work, a positively improved condition may be the final result. But, owing to the high arterial tension induced by the action of digitalis, this desirable nutritive condition cannot be permanently maintained. For we have already found that the nutritive interchange between the blood and perivascular tissues is effected exclusively through the arterial capillaries.[1] With this unduly high arterial tension, the blood is sent through this vascular area into the venous capillaries and veins so rapidly that the nutritive interchanges are very greatly impeded or totally abolished. Consequently, if digitalis is given in large quantities or continuously it prevents the nutritive fluids and pabulum from gaining access to the perivascular tissues and system, but, at the same time, it augments vital action, interrupts proteid metabolism, both by disturbing oxidization and by these marked changes in the vascular phenomena.

With these fundamental principles well in mind, we are in a position to state the physiological and therapeutic value of digitalis.

[1] THE MEDICAL NEWS, July 25, 1891, p. 98.

Before considering the action of digitalis in detail, it will be well to study the active principles a little more closely, if we wish to understand accurately the physiological and therapeutic results to be obtained from its use. We find that digitalis contains four decidedly active principles, three of which are said to have almost identically the same action, while the fourth, digitonin, has an effect almost opposite, poisoning and weakening the muscular activity of the heart and lowering the arterial tension.

Therefore, in using powdered digitalis, one of its contained elements is opposing the action of another set. The same holds true when the infusion is used, because the digitonin is freely soluble in water, but the digitoxin is insoluble and the digitalin and digitalein are only sparingly soluble in water. But with the tincture, the reverse is true; digitoxin, the most active stimulating principle, is freely soluble; digitalin and digitalein are sparingly soluble, while digitonin is insoluble in alcohol. Consequently, when the tincture is used, and especially a tincture made from the fresh leaves, we have in solution the three elements that act alike and comparatively little or none of the opposing agent, digitonin, to counteract the action of the other three. Therefore, in speaking of digitalis and its actions, the tincture is the preparation to be used.

Briefly and concisely stated, digitalis shortens the systole, prolongs the diastole, increases the intrinsic muscular contractility of the heart, poisons the muscle protoplasm, heightens arterial tension, thereby reducing the nutritive interchange between the blood and the perivascular tissues, at the same time primarily lowering the blood-pressure in the splenic arcade and renal vessels. The well-known physiological law that when the heart's action is augmented and the general arterial tension heightened, the blood-pressure in the splenic arcade is lowered, and *vice versa*, enables us to clearly explain the diuretic action of digitalis. It also perfectly elucidates the reason why digitalis acts so well as a diuretic in some instances and entirely fails in others.

Cognizant of these physiological laws, we find that when digitalis is given to a healthy individual, the heart's action is slightly augmented and the general blood-pressure is increased, while that of the splenic arcade is decidedly lowered. Following upon these vascular changes, and as a necessary sequence, an abnormally large volume of blood passes through the vascular areas of the kidneys; and owing to the generally increased blood-pressure, the general rapidity of the blood-current is increased. Now, if there is no impediment to the escape of venous blood from the renal veins, the blood simply flows more rapidly through the organ, so that the augmented volume is fully accommodated. The increased rapidity of the current of blood in the renal vessels allows much less time for each volume of blood to be in contact with the bases of the epithelial elements; consequently, a smaller quantity of effete material is taken up from the blood-stream by the vital action of the epithelial cells and necessarily a proportionately smaller quantity of waste matter is discharged by them into the lumen of the uriniferous tubules. The same is true for the transit of fluid through the walls of the capillary vessels forming the Malpighian tufts. In this way the increased volume of blood is counterbalanced by the greater

rapidity of the blood-current; and the physiological excretory function of the renal gland practically remains unchanged.

If, on the other hand, digitalis is administered under pathological conditions in which the action of the heart is feeble, the general arterial tension low, and an obstruction to the exit of blood from the renal vessels exists—as is the case in a general venous engorgement from any cause, or better in the parenchymatous lesions of the kidneys, in which the secondary or venous capillaries of the organ are obstructed by the pressure exerted by the swollen epithelial cells lining the convoluted and straight tubules—an entirely different result is obtained. Now, the digitalis increases the power of the heart's action, heightens arterial tension and raises the blood-pressure to the normal standard or above, and greatly increases the volumetric tension in the splenic arcade and in the renal arteries; but, owing to the venous obstruction existing beyond or within the kidney, the blood cannot be accommodated, so that it passes more rapidly through the renal vessels. As a result, the increased volumetric pressure brought to bear upon the capillaries constituting the Malpighian tufts is enormously increased and one of four things must occur: *First*, the water of the blood may find its way into the uriniferous tubules; *second*, the venous obstruction may be overcome and the blood more rapidly carried through the kidneys; *third*, the vessels forming the Malpighian capillaries may rupture and allow the blood to pass out into the uriniferous tubules to be discharged with the urine; *fourth*, the renal circulation may be arrested. The first and second conditions most commonly result. First the water of the blood passes off through the Malpighian tufts into the uriniferous tubules, thus diminishing the volume of blood to be forced through the secondary plexuses of the kidneys; a little later the increased volumetric pressure, which has been somewhat reduced by the escape of the water, causes the current of blood to move more rapidly through the secondary capillary plexuses in the kidneys. As a result, a large volume of blood moves out of and through the kidneys in a given space of time, more blood is brought in relation with the renal cells and an increased quantity of effete material is taken up from the blood by the physiological action of the epithelial cells lining the uriniferous tubules, and discharged into the lumen of the excretory ducts. Thus, by converting an almost stagnant renal circulation into one of normal or even augmented activity, the elimination of both the watery and solid ingredients of the urine is greatly increased and the body protected from the poisonous effects that must follow their retention in the system.

From this it naturally follows that when the heart's action is fully up to the normal standard, and the renal circulation unobstructed, digitalis will simply drive the blood through the kidneys more rapidly, and will not produce diuresis. In diseased conditions in which there is no venous obstruction, if any effect is produced upon the renal secretion the elimination of the solids will be diminished. Digitalis first stimulates and then weakens the heart's action; by the high tension produced the nutritive system is physiologically starved.

Considering the heart simply as a mechanical pump, wholly independent of the physiological laws governing its movements and nutritive vitality, we ought to be able to favorably influence its action by the internal administration of digitalis, especially if there are organic changes in the valves. This line of reasoning, however, is inconsistent, because it assumes a physiological action for the drug and a mechanical action for the heart, independently of the normal laws governing the movements of the organ. This one-sided method of reasoning is largely responsible for the differences of opinion and the variable results obtained from the internal use of digitalis. On the other hand, if we keep clearly in mind the physiological and mechanical laws associated with the heart's action and the drugs acting upon the organ, accurate deductions can be made.

Beginning with the mitral lesions, we find, from a purely mechanical standpoint, that when digitalis is administered in a case of mitral stenosis, the mechanical defect is somewhat compensated for by a shortening of the systole and prolongation of the diastole, thus affording the left auricle more time to force blood into the ventricle. If, now, the force of the systole is augmented, in addition to the shortening of its duration, a larger volume of blood will be sent into the aorta; if the arterial tension remained normal, the general nutritive condition of the system would be improved.

In case of mitral incompetency, the time during which regurgitation can occur is shortened; and here, as in the stenosis, if the force of the systole is augmented, in addition to the shortening of its duration, then the same improved condition of the general circulation and nutrition is established. If, at this point, heightened arterial tension and increased activity of circulation would establish a more perfect and effectual nutritive condition—as Dr. Fothergill assumed that it did—digitalis would be the remedy *par excellence* in the treatment of organic mitral affections; but, unfortunately, physiology teaches the reverse: nutritive interchange is not instantaneously effected between the blood and the perivascular tissues, but depends upon a somewhat slow flow of a large volume of blood through the arterial capillaries. When the blood has passed into the intermediate and venous capillary systems and on into the veins, nutritive activity is practically at an end; with high tension and active circulation, nutrition is reduced to the minimum or totally abolished.

Clinically, this law is fully sustained, for it is a well-known fact that, when high tension is developed that cannot be overcome, death rapidly ensues.

These physiological vascular and nutritive laws clearly explain the so-called cumulative effects of digitalis; they also elucidate the good effect that follows its temporary use, and the bad results so frequently observed when the drug is taken continuously, as well as the empirical statement, so commonly found in text-books, that the administration of digitalis must be intermittent and not continuous.

While digitalis mechanically improves the conditions associated with mitral lesions, by heightening the tension in the aorta and coronary arteries it at the same time rapidly lowers the nutritive supply of the cardiac muscle; the blood is forced through the arterial capillaries of the heart so rapidly that sufficient time is not allowed for the nutritive pabulum to be taken up by the perivascular structures. As digitalis is a non-nutritive

compound capable of calling into action the inherent and vital forces of the cardiac muscle, it will of necessity temporarily improve the mechanical action of the heart and cause it to accomplish more work, as a result of which the histological integrity of the muscular elements is impaired; at the same time the drug lowers the nutritive supply and causes progressive deterioration of the muscular tone.

Consequently, when digitalis is given, it becomes almost impossible to develop a truly physiological and compensatory hypertrophy, and as the attainment of this is the chief object in the treatment of all cardiac affections in which the mechanical action is defective, the use of this drug or any other of similar nature is constantly thwarting our endeavors. With a fully developed and sustained cardiac hypertrophy sufficient to compensate for the mechanical defect in the valvular apparatus, the condition of the patient is physiologically normal and may continue so for years.

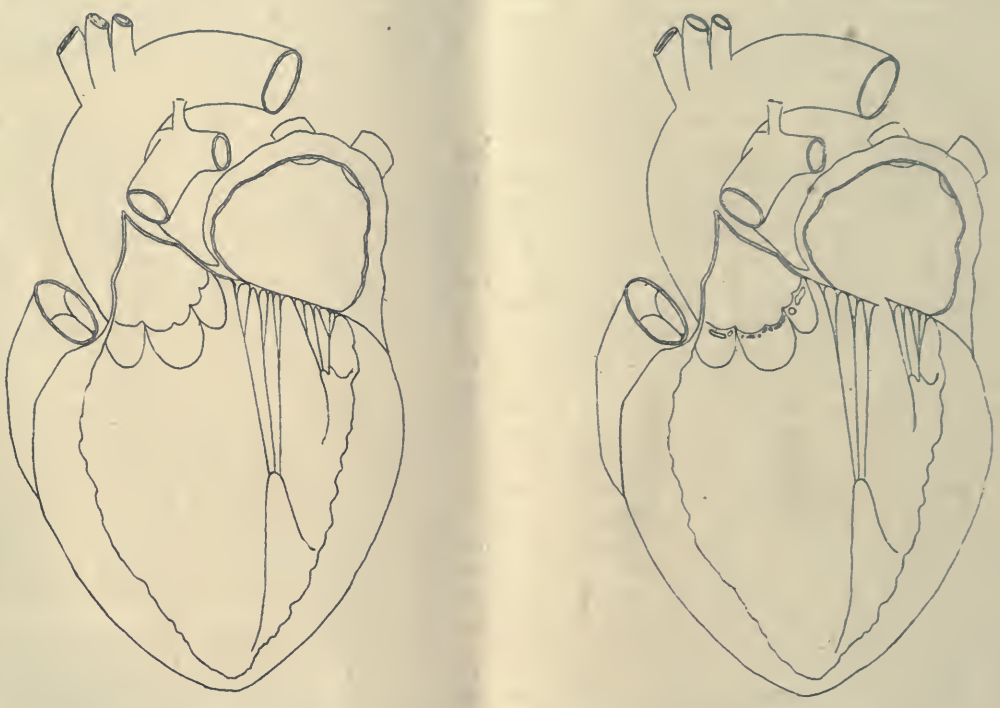
muscle and regulating the rhythm of the heart, this functional derangement can be rapidly dissipated and the action of the heart and the valvular sounds restored to the normal.

The slowing of the heart's action under the influence of digitalis appears largely due to the increased resistance to the onflowing blood by reason of the unduly high arterial tension, and later, to the impaired nutritive power of the cardiac muscle, rather than by a direct action of the drug upon the organ or its nervous mechanism.

Viewed in this light, digitalis can only be of temporary service; its continuous administration in doses sufficient to produce the decided action of the drug must of necessity be followed by harm.

As the weight of clinical, experimental, physiological and theoretical evidence all conclusively show that digitalis damages the heart-muscle by cutting off its nutritive supply, and that it has little or no tendency to

a FIG. 1. *b*



a. Normal heart, showing perfect closure of the mitral valve, and normal aortic semilunar valve-segments.

b. Functional derangement, showing imperfect closure of mitral valve, but without organic changes; also, congenital perforations in the aortic semilunar segments.

In the common condition of functional regurgitation at the mitral orifice so well illustrated in Fig. 1 and fully explained in the first lecture[1] on this subject, digitalis, by temporarily increasing the working power of the heart, and, at the same time, still more decidedly impairing the nutritive condition of the cardiac muscle —as already explained—causes the mitral regurgitation to remain stationary or even to progress, and the murmurs are heard with greater intensity. On the other hand, by increasing the nutritive supply of the cardiac

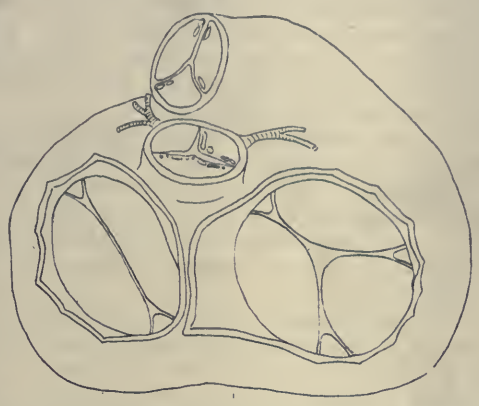
[1] THE MEDICAL NEWS, May 23, 1891, p. 585.

produce or maintain a compensatory hypertrophy of the cardiac muscle, I have ceased to consider or to use digitalis as a cardiac stimulant, and especially as we have so many far more efficient agents.

In aortic lesions there can be no possible excuse for using digitalis. Admitting that digitalis augments the force of the heart, in addition to shortening the systole, and thus enables a larger volume of blood to be thrown into the aorta, the increased arterial tension and the prolonged diastole permit of increased regurgitation. Accompanying this there is the progressive cutting off of the nutritive supply of the heart. Were it not for the

heightened tension produced by digitalis and the consequent diminished nutritive supply to the cardiac muscle, and the increased activity of circulation in the coronary arteries, the drug might be used with advantage in aortic stenosis, but never in aortic incompetency.

Fig. 2.



Illustrating the congenital perforations in the aortic and pulmonary semilunar segments.

Many cases of aortic regurgitation, however, depend upon congenital perforations in the semilunar segments, as illustrated by Fig. 2 and explained in my second lecture on this subject.[1] These defects in the valve-segments often give rise to decided physical signs, and the diagnosis of organic lesions of magnitude—while, in truth, the mechanical leakage is quite small, the condition does not grow worse, and the physiological actions of the heart and circulation are not at all disturbed. In these cases, the administration of digitalis, in moderate doses, appears to strengthen the heart, so long as the administration is intermittent and the dose not large enough to give rise to positively bad effects. In this way it has been conceived that the drug can be used to advantage in aortic regurgitation; but used continuously in case of a truly organic lesion, it has caused not only serious but absolutely fatal results.

I have frequently been asked why it is that, digitalis being such a perfect drug as it is claimed to be, patients are but temporarily improved under its influence, but almost invariably get worse before the heart is gotten into a desirable condition. I trust that this question has been satisfactorily answered and explained by the facts presented in connection with our knowledge concerning digitalis.

MEDICAL PROGRESS.

A Teratological Curiosity.—There has recently been on exhibition in Paris a unique twin-monster, of the class pygopagus. The twin-sisters were born thirteen years and a half ago, in Bohemia, the labor, at which the village midwife officiated, presenting no particular difficulty. The mother, then twenty-two years old, had, two years previously, given birth to a girl of normal physique. The sisters are of very fair complexion, small for their age, resemble each other closely, and, when seen seated side by side, hardly convey the impression that they are united by so intimate an anatomical bond. Directly, however, one sister moves, the other is constrained to follow. The trunks are not parallel, the axes of the spinal columns forming an angle the apex of which is situated below at the junction of the pelves. Each trunk is twisted on itself at an angle of about 45°, so as to turn the faces forward and to incline the heads somewhat inward. Viewed in profile, it is at once seen that the sisters are united by the posterior wall of the pelves, just as were Hélène-Judith, a description of whom is met with in old works on teratology. The apex of the angle or V formed by the conjunction of the trunks is constituted by the intimate soldering, in the median line, of the sacral and coccygeal regions, and, laterally, of the four buttocks. The composite pelvis is abnormally large, composed as it is of four ossa iliaca, from which spring four well-formed lower extremities. Below the sacral junction, between the four buttocks, in the quadrilateral and dome-like space bounded by the four thighs, is found a region the description of which is of special interest. At first view, one would be inclined to believe that the space contained only azygos parts—viz., one urethra, one vulva and one anus. There is, in effect, only a single urethral orifice from which urine has been seen to issue. But as no sound has ever been introduced through this opening, the existence of two distinct bladders can only be inferred from the fact that the desire to urinate is not simultaneous in the sisters. Immediately anterior to the urethra is situated a single, fairly well-developed clitoris. From either side of this organ is directed from before backward a rudimentary labium minus. Encircling all these parts is a nearly oval collar, representing two labia majora, which limit a single vulva. This vulva contains two vaginæ, distinctly separated from each other by a complete partition, the entrance to each vagina being guarded by a crescent-shaped hymen. Between the two vaginæ and the single anus, situated at a short distance behind, is a frail perineum. The rectum is probably single up to a certain height (no rectal examination was allowed), for the desire to defecate is simultaneous; but it is certain that there exist two large intestines. The anus, clitoris and urethra are situated in the median line corresponding with the antero-posterior diameter of the vault formed by the sacro-gluteal junction. Breisky, who, in 1878, was professor at the German Medical Faculty of Prague, and who examined Rosa-Josepha when the latter were only six months old, states that he then noticed a remarkable asymmetry of the crania, very plainly appreciated when the heads were viewed from above and behind. The foregoing details will have prepared the reader for the information that in Rosa-Josepha we have to deal with two perfectly distinct psychical personalities. The only parts that can be considered common property are the lower portions of the genito-urinary apparatus (urethra, clitoris and vulva), the rectum and perchance the lower end of the vertebral canal. That they are independent beings is evidenced by the fact that one sister can sleep while the other remains awake; one can occupy herself at a task that does not interest the other; one likes beer, the other wine; one is very fond of salad, which the other dislikes, etc. Moreover, one sister may be thirsty without the other experiencing any such sensation. The radial pulses do not beat syn-

[1] The Medical News, May 30, 1891, p. 611.

chronously. There is a zone of common sensibility to afferent impressions, limited to a cutaneous space corresponding to the transverse mass situated between the two pelves. The movements of this conjoined twin are free and graceful enough. When one sister walks, her companion is not obliged to follow backward. Generally, the two inner feet advance together, to be followed by the synchronous movement of the two external ones. Either sister can walk while supporting the weight of the other. In order to accomplish this feat it suffices for the bearer to incline her body anteriorly, while the other one, having lifted up her feet from the ground, reclines on her sister's loins. They have been seen to progress on only two and on three legs respectively, mount the stairs, dance, etc. In waltzing they are very proficient. One had the croup when twelve months old without communicating the disease to her fellow. Soon afterward the non-croupous twin was seized with convulsions, the other remaining unaffected. How can we explain the existence of such a phenomenon as Rosa-Josepha? Dareste has shown that the explanation lies in the accidental fusion of two germs developed in a single ovum, and enclosed in a single chorion. The two germs, represented at the early period of development by their primitive streaks, must be inclined the one toward the other, so as to form a V, the union occurring at the future sacral region. In the case of Rosa-Josepha this must have taken place toward the end of the first fortnight after fecundation, when the medullary canal had not quite closed posteriorly. The single urethra, clitoris, vulva and rectum are easily explicable on this theory; but, as the allantois is already formed, these conjoined twins probably always possess two large intestines, two bladders and two uteri.—*Paris Correspondence, Lancet*, July 18, 1891.

The Value and Limitations of Tuberculin.—From a study of nineteen cases of pulmonary tuberculosis treated with tuberculin, DENISON in a paper read before the Colorado State Medical Society, formulates the following conclusions:

1. Tuberculin is a remedy to be classed with stimulants, hypophosphites, chloride of gold hypodermatically used, exercise, high altitudes, and cold, dry air; it is too powerful to be indiscriminately used, and the cases in which its use would be advantageous remain to be determined.

2. It is unreasonable to expect that tuberculin will be useful in septicemia or in any poisonous blood-state other than tuberculosis.

3. Tuberculin should be used not as a substitute for, but as an aid to climate and other natural methods of cure; especially are high altitudes and exercise indicated, if not otherwise contra-indicated, because they favor pulmonary expansion and aëration.

4. Only local reactions in the affected tissues are to be aimed at. High or prolonged febrile reaction is, if possible, to be avoided. The minimum dose that will accomplish this purpose is to be used; it is preferable to permit at least a day to elapse between the subsidence of one reaction and the possible production of another.

5. Deficiency of pulmonary expansion and aëration, whether a result of the injection of tuberculin or of pre-existing conditions, is a contra-indication to persistence in treatment.

6. The test for the proper expansion and aëration of a tuberculous or fibro-tuberculous lung consists in a comparison of the spirometric record with the bilateral measurements of the chest and with the physical signs.

7. The stage of the pulmonary affection has not so much to do with the question of using tuberculin as has its extent and localization, the febrile course and the expansion and aëration of the affected lung. It were desirable that the average daily range of temperature should not exceed two degrees, and the patient should be much of the time in the open air.

8. The diagnostic value of the injection of small quantities of tuberculin is borne out by the manifestation on auscultation at suspected or affected spots in the pulmonary structure of an *increased roughness of a previously existing broncho-vesicular respiration;* or by *high-pitched harsh breathing* that previously had been but enfeebled.

9. With the appearance of unfavorable physical signs, indicative of bronchial obstruction, or moist râles suggestive of softening, it would be well to intermit the injections of tuberculin and for a while substitute those of iodine, or to give iodine in some form internally, or to use inunctions of the oleate of mercury over the affected lung, until a resumption of the treatment with tuberculin seems safe.

10. As to the permanence of the effects produced by treatment with tuberculin, there is to me no reason to expect more lasting results than are to be obtained from any other agency. There is no reason why, after the disappearance of bacilli from the sputum, in the course of treatment with tuberculin, they should not again appear, as they do in the case of climatic treatment and after injections with the double chloride of gold and sodium. It is probable that the effect of tuberculin is temporary. Immunity from tuberculosis cannot be hoped for, except under such other conditions of healthful living as would insure it. Tuberculin is not a remedy suitable for the great majority of pulmonary consumptives in preference to a proper change of climate. Its efficacy does not equal that of the latter, to which, however, it may serve as an important adjuvant in a large number of selected cases.

Glioma of the Retina.—COLBURN (*Chicago Medical Recorder*, July, 1891) reports five cases of glioma of the retina in children four months, eight months, three years, and six years old, respectively (in one the age is not given). In two, after the lapse of a considerable interval, recurrence had not followed enucleation of the affected eyeball. One died with meningeal and one with cerebral symptoms. In the fifth, the disease had progressed to such a degree as to forbid operative interference.

Sunstroke.—The following circular has been issued by the Pennsylvania State Board of Health:

This dangerous illness is caused by excessive heat of the blood (from 100° to 110° F.), which produces great depression of the nervous system. It occurs during the hot season of the year, and usually to those exposed to the hot sun, but it sometimes occurs at night, and also to those exposed to great heat, in glassworks, laundries, furnaces, bakeries, iron-foundries, and the engine-rooms

of steamships. It is largely confined to the hot, close streets and passages of the cities, but is not unknown in the country. Those habituated to the use of alcohol, and the delibitated, are especially predisposed to attacks.

Dark, close-fitting clothing and such as compresses the chest and neck should be avoided during the heated term. For those obliged to labor in the sun, light clothing and a straw or light felt hat, permitting free circulation of air, are preferable.

On very hot days, one should drink frequently, but in small quantities. A large quantity of any iced drink entering the stomach at one time is injurious.

Cool water, into which oatmeal has been stirred, is a safe and refreshing drink. Water should not be drunk in considerable quantities at a temperature lower than that of spring water, namely, 56° F. Immediate death is often caused by "ice-cold" drinks. The immoderate use of alcoholic beverages is also dangerous.

The sleeping-room should be freely ventilated and cool. Constipation of the bowels should be avoided. When overheated, work slowly, frequently cooling the head, chest and back with cold water. Keep a wet cloth or some green leaves in the hat on the head, frequently wetting them with cold water. When, on a very hot day, the skin becomes dry and uncomfortably hot, a burning sensation is felt in the head, and the face is flushed and the eyes bloodshot, with a frequent tendency to urinate, the person should immediately quit work, retire to a cool place and rest in quietness; and if not speedily relieved of the sensation of heat, take a cold bath.

The attack may be very sudden and take the form of delirium in which the patient rushes wildly about and may attack those around him; or he may become weak and sink to the ground as if in a fainting spell or stupor. Loss of consciousness and mental disturbance may be only partial. Nausea or sickness at the stomach often precedes the onset. Convulsions may occur.

Sunstroke must be carefully distinguished from heat-exhaustion, in which the general symptoms are similar to those of sunstroke, but the bodily temperature is below the normal. The difference can be at once recognized by feeling the skin underneath the clothing: in sunstroke the skin feels burning hot; in heat-exhaustion it is cold.

Treatment.—1. Carry the patient into a cool and shaded place, where there is plenty of pure, fresh air.

2. Strip his clothing to the waist, and place him in the recumbent position.

3. Pour cold water (ice-water is best) upon his head and chest until consciousness returns. The points at which the blood may be most effectually cooled are the wrists, the temples, and the ears, because at those points it approaches the surface more nearly in considerable quantities. Ice may be applied to the head and chest and rubbed over the body, but if the skin is cold no ice should be applied. Internally, small doses of brandy may with success be administered; but in all cases of sunstroke the patient should, as soon as possible, be placed in charge of a competent physician.

The patient should do no mental work for some months, and should keep free from all excitement. Persons who have once suffered from sunstroke are liable to a second attack. Insanity, in some of its varied forms, frequently follows sunstroke.

In heat-exhaustion give alcoholic stimulants and place the patient in a hot bath, so as to raise the bodily temperature.

Ignipuncture for Hypertrophied Tonsils.—Cullen (*Cincinnati Med. Journ.*, 1891, vi. 5) states that the galvano-cautery may be employed either to completely dissect the hypertrophied tonsil or to cause a diminution in size by cicatrization from puncture. After an application of carbolic acid and cocaine, he introduces at one sitting an appropriate electrode at moderate, red heat into two or three lacunæ close together, and repeats the procedure in from three to six days. The operation is followed by a soothing antiseptic spray. If the subsequent hemorrhage should be considerable he administers tannic and gallic acids.

The following are the main indications for the employment of the galvano-cautery in the treatment of hypertrophy of the tonsils: When the tonsils have ceased to perform their functions by reason of interstitial thickening and occlusion of their lacunæ, the mouths of the crypts becoming blocked by sebaceous matter, which rapidly decomposes, they form an excellent culture-medium for various pathogenic germs, which may ultimately find their way into the lymphatic system; when a tonsil shows itself liable at short intervals to become inflamed and give rise to peritonsillar abscess; when the tonsil is so situated that it is a matter of difficulty and danger to use the tonsillotome, with extensive adhesion of the pillars, and a liability to severe hemorrhage; in all cases in which the patient is of a hemorrhagic diathesis or in other cases in which alarming hemorrhage is feared; when patients will not consent to the use of the knife and yet the demand for the removal of the gland is imperative.

Maternal Impressions and Monstrosities.—Ground (*Northwestern Lancet*, August 1, 1891) reports the case of a woman who, in the eighth month of pregnancy, aborted with a monster, weighing five pounds. The vault of the skull was absent, the cranial cavity being occupied by the meninges and a small mass of cerebral structure. The spinal processes and the lamina of the cervical and dorsal vertebræ were wanting, so that the cord was exposed as far down as the lumbar region. In addition, there was a large umbilical hernia. Some time later, a pregnant woman, coming for consultation, saw the specimen preserved in a jar. Naturally frightened, she could not exclude the hideous picture from her mind. In the course of several weeks this woman aborted with a fetus of four months—a monster, crudely resembling that of the first case; the vault of the skull and the spinal canal were open. Both women were primiparæ. The first has since given birth to a well-developed female child. Both monsters were of the female sex. In the first a history of a mental impression was wanting.

Hemiplegia followed by Restoration of the Knee-jerks in a Tabetic.—Hughlings Jackson and James Taylor (*British Medical Journal*, July 11, 1891) have reported the case of a man, forty-nine years old, with the symp-

toms of hemiplegia in addition to those of tabes dorsalis: lightning pains, ataxia, contracted pupils that reacted with accommodation but not on exposure to light, and absent knee-jerks. There had been two attacks of hemiplegia, with an interval of three days. Forty-seven days after the second, the knee-jerk was elicited upon the right but not upon the left. On examination, twenty-two months subsequently, the right knee-jerk was readily elicited, the left but feebly on reinforcement. The explanation of the phenomenon must be dependent upon a heightened irritability of the ganglion cells of the anterior horns of the spinal cord, occasioned by the secondary descending degeneration of the crossed and direct pyramidal tracts.

Immunity from the Diplococcus Pneumoniæ Conferred by a Glycerin Extract of Hopatized Lung.—VASSALE and MONTANAIRE (*Gaz. d. Ospit.*, No. 19) removed soon after death from a case of croupous pneumonia in the stage of gray hepatization about an ounce and a half of pulmonary tissue, which they cut into small pieces and placed in a steam sterilizer, then rubbed up, and added thirty parts each of distilled water and glycerin; the mixture was well shaken and filtered. Of this filtrate nine c.c. were injected, in three parts, into each of two rabbits. These and two control-rabbits then received one c.c. of a virulent emulsion of a hepatized lung. The control-animals succumbed to pneumonia, the protected animals survived. A rabbit which first received an injection of a glycerin extract of a healthy lung and then an inoculation from a hepatized lung, died of pneumonia. —*Wiener klinische Wochenschr.*, June 4, 1891.

Psorosperms in a Case of Paget's Disease of the Glans Penis.—PICK (*Prager medicin. Wochenschr.*, June 17, 1891) has reported to the Society of German Physicians in Prague, the case of a man who presented an eczema of the glans penis that had existed a year and a half. The diseased weeping surface was ulcerated and displayed a tendency to proliferation of the epithelium, with the formation of nodules. An existing phimosis was thought to be the source of the disorder and was removed. Primary union took place and the condition improved—soon, however, to recur. The new nodules were removed. These presented microscopically, in addition to the small-celled infiltration common to eczema, typical carcinomatous proliferation within which was an abundance of psorosperms. Upon this a diagnosis of Paget's disease was made.

Operative Treatment of Morphine-poisoning. — In the *Detroit Emergency Hospital Reports*, June, 1891, is reported the case of a girl, twenty-one years old, not an opium-habitué, who had taken twenty grains of morphine. The respirations were but four in the minute and the coma was profound. Artificial respiration by Sylvester's method proved insufficient. The trachea was opened, a tube introduced, a hand-bellows attached and respiration thus maintained for three hours. At the end of this time, the reflexes returned and the restoration of the patient was assured. The bellows must be so constructed as not only to introduce air into the bronchi, but also to allow for the escape of the vitiated air. The action should, as far as possible, correspond to the usual respiratory action.

The Re-union of Cut-off Fingers.—POPOFF (*Vratch*, No. 14, 1891) has reported the case of a soldier, who, while hewing a block, struck his left hand with an axe. Thirty or forty minutes after the accident the index, middle and ring fingers were found to be completely severed through their first phalanges, at the line of the interdigital fold, and the little finger through the first inter-phalangeal joint, all four being held by bridges of skin. The detached parts were at once replaced and sutured. The little and index fingers united perfectly, though with impaired mobility. The second and third phalanges of the middle finger sloughed, but the first united. The ring finger became gangrenous and was thrown off.—*The Provincial Medical Journal*, June 1, 1891.

Public Institutions as Sources of Impairment of Vision.—LIPPINCOTT (*Pittsburg Medical Review*, July, 1891) maintains that blindness is increasing in the United States disproportionately to the increase in population. He holds that granular conjunctivitis is an important factor in the causation of impairment of vision, that it is a contagious disease, the dissemination of which is facilitated by the agency of orphan asylums, orphan and reform schools, and similar institutions, from which it can be excluded by rigid inspection (including systematic eversion of the eyelids), and the spread of which can be checked by absolute isolation of infected cases, together with appropriate hygienic regulations.

The Treatment of Surgical Tuberculosis.—The Paris correspondent of the *Wiener medizinische Presse*, July 12, 1891, states that at a recent meeting of the Académie de Médecine, LANNELONGUE presented a new method of treating tuberculosis, especially surgical tuberculosis. The treatment is not directed at a local destruction or inhibition of the growth of the tubercle bacilli, but at a conversion of the tuberculous tissue and its immediate surroundings into fibrous tissue—in a word, at encapsulating the tuberculous mass, which is accomplished by injecting about it small quantities of chloride of zinc. The results thus far obtained have been gratifying.

The Contracted Pelvis as an Evidence of Degeneration.—As a result of his investigations, WIEDOW (*Münchener medicin. Wochenschr.*, June 30, 1891) concludes that the various types of deformed pelves are but expressions of an abnormal constitutional condition. In thirty-five women with deformed pelves he found cretinism in four, anomalies of the skeleton in ten, small growth of the body in seven, anomalies of the internal and external genitalia in eleven, and struma in three. The causes of these anomalies may be operative in the germ or during intra-uterine or extra-uterine development.

The Cure of Chronic Peritonitis by Laparotomy.—HENOCH *Berliner klin. Wochenschr.*, July 13, 1891) presented to the Society of Physicians of the Charité, at Berlin, the case of a girl five years old, who, following a fall, developed considerable ascites. Not yielding to thrice-made puncture, laparotomy was performed. On opening the abdominal cavity, the peritoneum was found not only reddened and thickened, but covered with innumerable grayish-red miliary nodules. Carefully examined microscopically, the nodules presented nothing tuberculous in character. The child recovered perfectly.

THE MEDICAL NEWS.
A WEEKLY JOURNAL
OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, AUGUST 29, 1891.

THE PROPER SPHERE OF THE OPTICIAN.

IT is but a few years since the province of the druggist was clearly outlined, and its delimitations, in contra-distinction to that of the physician, sharply determined. A little further back in history it was found that the barber and the surgeon had functions that very properly required differentiation. When the barber was restricted to his proper field of action by other barbers that had become or had determined to become surgeons, there was doubtless much bitterness of heart and outcries against the injustice on the part of those that kept as their sign the red-banded post. In the same way, when the apothecary, if he would continue to practise medicine, was compelled to obtain a medical instead of only a pharmacological education, he doubtless also thought himself aggrieved. In both cases the world in general and each of the four professions in particular, is finally the better off. No druggist of character would wish the old days back.

Another great stride in the march of medical progress must soon be taken, and when it is resolutely done the world will be by far the better. The optician, *quâ* optician, must be forbidden to prescribe spectacles. It should be as illegal for an optician to prescribe glasses as it is for a pharmacist to prescribe morphine or arsenic. Both the optical instrument and the drug are medicinal agents, and only a physician is fitted to judge of the propriety of their use. It is a common error prevalent in the community, and one that some few ignorant opticians have accepted, that the prescription of spectacle lenses is a purely optical, physical, or mechanical process. This is a most grievous mistake, and one that is costing thousands of innocent people their happiness, health and vision.

Every pair of glasses worn has a medical significance, and every case of refraction resolves itself into a question of physiology, pathology and pathogeny. The merely physico-optical part is but the simple alphabet of the matter—the most primary rudiments of the therapeutics of ocular, and of ocularly originating neurological affections. A few considerations may help toward an apprehension and acknowledgment of this great truth:

1. The eye is a living, not a dead, camera-obscura, and the simple mechanico-optic laws will apply to it only in a subordinate and very limited sense. The purely optical laws must be used by a physician, by a living intelligence, in accordance with manifold and changing circumstances and ever-varying function. Even when no disease exists other than ametropia and ametropically-caused conditions, there are physiology, life, occupation, hereditary factors, anisometropia, and a possible multitude of dyscrasiæ, of which only a physician can judge.

2. It is admitted that when the optician suspects disease he should refer the patient to the physician. The admission is death to the contention. Only a physician *can* suspect many diseases of the eye, or diseases caused by ocular abnormality. The proof of this lies in the horrible fact always turning up with mournful regularity at the oculist's office—the fact of ruined eyes because the opticians have *not* suspected. Glaucoma *cannot* be suspected except by one who has studied glaucoma—*i. e.*, by a physician. Glaucoma *is not* suspected by the optician, and while he is trying to find a glass for the eye the eye is ruined. Choroidal, retinal, and optic-nerve diseases of a hundred kinds cannot be suspected by the optician, and while he is pottering with glasses blindness overcomes the patient. The horde of reflex neuroses of ocular origin cannot be known by the optician, and their causes cannot be stopped by means of any purely optical knowledge.

3. Ametropia in persons under forty-five years of age (and often in those from forty-five to fifty-

five) cannot be accurately diagnosticated except by the use of a mydriatic, and a mydriatic should never be used, and even now cannot legally be used except by a physician. Ophthalmologists are in thorough accord that refraction without paralyzed accommodation is mere guess-work, and is not scientific. It is the small degrees and the unsymmetrical axes of astigmatism, the so-called spasms of accommodation, the relations of ametropia and heterophoria, the existence of anisometropia, the tendency to progressive myopia, etc., that, uncorrected, are breeding a host of ills in the hyperesthetic and ocularly overworked urban resident, and these are facts that can be diagnosticated and proceeded against solely by a *medically* educated mind.

4. As a last resort the optician claims the presbyope as his own. This claim must also be denied. The reasons for the denial are patent. Only a physician can say when the presbyopic process is complete. Some power of accommodation often persists up to fifty or sixty, and even a greater age, and may always be the exciting cause of pathologic reflexes. But most important is the fact that it is in the presbyope that glaucoma and cataract arise—glaucoma in which the loss of a day may mean blindness, cataract that requires constant medical watchfulness and medical advice to prevent many evil results.

Many other reasons of a like kind will arise spontaneously in the mind of the student of the living eye, or will be forced upon those that yield ungraciously to the growing need. It is but fatuous self-deception to charge the medical specialist with avarice or with jealousy of the optician; it is only struggling against the inevitable to attempt keeping the two professions longer united. The prescription of glasses is one sort of work, the scientific and artistic filling the prescription is another kind of work. There is not the most far-away tendency of the physician to belittle the function of the optician. The physician in many ways is greatly dependent upon the optician, and is helped by him to realize the common aim—the good of the patient. The two professions must work in harmony, and this can never be so long as their respective spheres are not delimited.

The greatest enemy of the optical profession is he that contends that opticians are capable of prescribing spectacles. The blunders that the optician is repeatedly making, and, since he is not a physician, must necessarily make in attempting to prescribe, are bringing upon him the increased contempt both of the physician and the public. If the optician *could* prescribe without grievous mistakes, the opposition of all the physicians in the world would not and should not change the common custom or affect the optician's reputation. The only way to elevate the optical profession is to restrict the optician's field of action to such work as he can do rightly and well. The scientific manufacture and the artistic fitting of a perfect pair of glasses according to the prescription of the physician is an art requiring high qualities of mind and skill, and, when it comes to be estimated at its proper therapeutic value, will command increasingly more and more respect.

It is wretched ethics and very far from our aim to encourage malpractice suits, but such suits often correct and open the eyes of the community to existing wrongs. One of the greatest advances in medico-legal progress, fraught with incalculable good to humanity, consists in the decision of the French courts, that it is illegal for an optician to prescribe glasses or give advice for any visual trouble. This has been called "a narrow technical theory," but by none who understands a tithe of the evils daily resulting from the non-existence of such a law in the United States.

SIMPLICITY AND INDEPENDENCE IN PRESCRIPTION-WRITING.

IN this day of extensive knowledge of drugs and of their physiological actions there is a great tendency to complexity of prescription. Impatient or dissatisfied with the slowness or uncertainty of action of a single remedy, the therapeutist is tempted to devise formulæ that will answer many and varied purposes. In this he is encouraged by the unfortunate practice of introducing into text-books formulæ the memorizing of which the student deludes himself into believing is the essence of therapeutics. He would be better taught if, instead, he were shown that the most effective treatment depends upon a knowledge of disease and of the action of individual drugs.

A drug should be prescribed for the effects that it will produce. Given alone, in this way, its action can be best studied. Experimental therapeutics in the lower animals has only a relative value, to be confirmed or modified by observation in man. There can be no objection to the intelligent combination of a number of remedies in a single prescrip-

tion; but they should be rationally combined, from a knowledge of their therapeutic effects, to accomplish definite results that it is known can only be obtained by such combination. The danger consists in the indiscriminate and routine use of such formulæ, as a result of which prescription-writing becomes merely mechanical, while the isolated action of a remedy escapes observation, and the lesson that every case should teach is lost.

Sometimes, of course, drugs are prescribed when drugs are not required. The mere existence of a valvular lesion of the heart or of derangement of the gastro-intestinal apparatus does not, by any means, indicate the administration of medicaments. The physician owes it to himself and to his patient not to prescribe unnecessarily. He has no more right to deceive or pretend under such circumstances than under any other.

To be successful, a therapeutist, besides being observant and conscientious, must be intelligent, original, independent, and have a distinct purpose in view. The prescriptions of such an one will always be simple, spontaneous, rational, and adapted to the individual case. To him ready-made formulæ are as obnoxious as they are unscientific.

INFLUENZA AND ITS COMPLICATIONS.

Though we are not at present cognizant of the ultimate cause of influenza, the evidence is sufficient and of such a character as to warrant the assumption of its toxemic nature; and the next step in this line of thought is to refer the etiology of the disease to microbic influence. Its epidemic occurrence, its transmission along lines of travel, its fatality among the debilitated, its peculiar symptomatology and its disastrous complications, all point to an infectious agency of origin.

Of the group of infectious diseases there is none to which influenza bears perhaps a more striking analogy than to diphtheria. Both occasion profound depression, from which recovery is tedious and tardy. Both are followed by the evidences of polyneuritis, especially manifest in the ocular and peripheral palsies, in the neuralgias, in the abolition of the reflexes, in the trophic changes that take place. In both are cerebral symptoms observed. One other manifestation—or rather group of manifestations—do these two diseases present in common, that is, those referable to the heart—a complex of symptoms that may be ascribed to inflammation of the vagus. The action of the heart is at first slowed, then accelerated and irregular; ultimately death may ensue from heart-failure, a result of degeneration of the cardiac muscle. In the recent epidemic this manifestation of cardiac deficiency was especially noticeable, and to it is the fatal result in not a few cases to be ascribed. The profound alterations in nerve and nutrition also afford sufficient explanation for the protracted convalescence and the long-deferred and oft imperfect recovery.

THE PATENT MEDICINE SUBSTITUTION BUSINESS.

"No one like a thief to catch a thief" is an old motto and one that is being illustrated in the proprietary medicine business. The nostrum-venders must now fight their imitators, and it is to be hoped that in this piratical and parasitical rough-and-tumble the public may become disgusted with the whole crew. Millionnaire patent-medicine venders are becoming as common as ward politicians, and no one will feel sorry that they must take some of their own medicine. It seems that almost every secret compound now has many imitations, and that there are a number of large manufacturers whose sole business it is to make these counterfeits. The standard article is imitated in originals, in qualities, appearance, name, and appearance of the packages, as nearly as it is possible or safe. Druggists buy these counterfeits and use their own printed wrappers to give them a personal guarantee of value and private manufacture. Whenever an imitation attains any considerable popularity it is probable that it will find imitations. And thus is again illustrated the old saw:

> These little fleas that do me tease
> Have lesser fleas that bite 'em,
> And these again have lesser fleas,
> And so *ad infinitum!*

THE HOT SPRINGS DISGRACE.

The excellent *Journal of the State Medical Society of Arkansas* very justly and courteously sets us right concerning the fiendish doctors and their drummers at Hot Springs. It is indeed a serious matter, and our banter was far from being meant as reproach to those that have heroically tried to make head against the disgusting abuse. Our own withers are far from being unwrung. It appears that the city, county, and State authorities have vainly tried to break up the practice, the licensing

and ticketing the drummers with badges being the last attempt to make these wretches odious. The bottomlessness of human shamelessness has frustrated all such attempts, and the execrable business still goes on. Our contemporary has our sympathy, and for the very evident reason that East and West alike—the whole profession, indeed—must willy-nilly share in the disgrace.

SOCIETY PROCEEDINGS.

SECOND CONGRESS OF TUBERCULOSIS.

Held in Paris from July 27 to August 2, 1891.

(Continued from p 199.)

AT the second session the subject of "The Identity of Human Tuberculosis with Tuberculosis of Fowl, of Cattle, and of Other Animals" was taken up.

M. CHAUVEAU presented a communication upon "The Identity of Human Tuberculosis and that of the Ox: an Experimental Study based upon Inoculation of Cows with Tuberculous Products obtained from Human Subjects." In his experiments with the products of tuberculosis in man M. Chauveau had been struck by the apparent identity of tuberculosis in different animals. He endeavored, particularly, to infect cattle with the products of human tuberculosis, so as to determine whether or not bovine tuberculosis would result. These experiments were conducted upon three lines: The ingestion of tuberculous matters, intra-venous injection, and subcutaneous introduction.

Infected food was administered to three young animals: one six months old, another eleven months, and the third one older.

The first was given a small quantity of a mass made with fragments of lungs obtained from a patient who died from acute miliary tuberculosis. This animal became tuberculous, as did a control-animal to which were given the products of bovine tuberculosis in the same manner. The lesions were confined to the digestive tract, consisting of a confluent eruption of tuberculous granulations on the peritoneum and small intestine; the liver also presented a few well-developed tuberculous granulations, while the respiratory and grandular apparatus were free from lesions.

The second animal also was given a mass composed of a fragment of lung from a case of miliary tuberculosis, to which was added a fragment of lung obtained from a case of caseous pneumonia. In this animal the lesions were limited to the respiratory apparatus, no lesions being found in the intestine or abdominal viscera; the lung presented a certain number of caseous masses, and the mediastinal glands were involved.

The third animal was given a mass made from a piece of lung from a case of caseous pneumonia. The resulting lesions were situated in both the digestive and respiratory apparatus; there existed a confluent tuberculous eruption on both the small intestine and peritoneum, while the rennet presented a lenticular eruption that had already reached the ulcerative stage; in the respiratory apparatus a fine eruption had begun to appear in the larynx, and was extending into the smallest bronchial ramifications.

The second series of experiments was intended to demonstrate the transmission of human tuberculosis to the ox by means of intra-venous injections. An emulsion was made with a piece of lung obtained from a young man who had died from acute tuberculosis. This was injected into the jugular vein of a three-months-old calf. The animal was killed on the twenty-ninth day, and at the post-mortem examination the bronchial glands were found tuberculous, while in the lungs granulations were present; these same lesions were found in a control-animal that received bovine virus in the same way. In a third series the subcutaneous method was employed. A mixture of tuberculous matter containing no solid particles was made with material obtained from a case of tuberculous arthritis. Injections were made in the subcutaneous tissue; in each instance a tuberculous tumor was obtained. A few hours after the injection has been made, a slight swelling appears at the site of injection; then follows a period of latency, succeeded in turn by an irritative process, resulting in tumefaction that does not disappear; this is the tuberculous tumor. In all such cases the nearest lymph-gland became swollen; in no case did the tuberculosis generalize itself, the nearest lymph-gland apparently arresting the process.

As a result of his experiments, M. Chauveau believes that the tuberculosis of man is absolutely identical with that of the ox.

M. VIGNAL next presented a communication on "The Non-identity of Human Tuberculosis and that of Birds." The experiments were made with a view to confirm the statements made a few years ago by MM. Nocard and Roux, that the bacillus of bird-tuberculosis was but an attenuated form of the bacillus of human tuberculosis. The experiments of M. Vignal were made to determine whether Koch's bacillus by passing through several cultures would not lose its virulence and become more like that of bird-tuberculosis. With this end in view, on the 4th of March a pheasant was inoculated with sputa obtained from a tuberculous patient. A guinea-pig that at the same time received a certain quantity of the preparation died very rapidly, demonstrating the virulence of the material used. The pheasant was living two months after the operation. Then the same pheasant was again inoculated with tuberculous virus, as was also a guinea-pig; the latter died, while the pheasant remained well. A third inoculation of tuberculous matter was made, and again the control guinea-pig died, while the pheasant remained well.

PROF. STRAUS and DR. GAMALEIA next presented a communication on "The Differential Characters of Human and Bird Tubercle Bacilli." The first character that differentiates these two bacilli is the appearance of the culture on a solid medium—cultures from human tuberculosis being dry, nodular, scaly and hard, while bird-tubercle cultures are unctuous, soft, and moist. Again, the bacilli differ in their pathogenicity, certain animals being susceptible to one culture and refractory to the other. Hens are refractory to human tuberculosis, while they readily die from bird-tuberculosis; while the contrary is the case with the dog. The rabbit and guinea-pig are susceptible to the action of both bacilli, but in

different ways. Guinea-pigs inoculated with human tuberculosis die, the viscera presenting apparent tubercles; while inoculations of the bird-bacillus will kill these same animals, but without leaving any macroscopic signs of the disease in the internal organs.

Straus and Gamaleia have also found that these two bacilli invariably preserve their peculiar properties and their special pathogenicity independently of the culture-medium employed. They endeavored by certain means to modify the two bacilli. The products of tuberculosis in birds were introduced beneath the skin, into the peritoneal cavity, and into the veins of rabbits and guinea-pigs, which died with tubercles in many organs. Fragments of these organs were introduced into a second series of guinea-pigs and rabbits, which in turn died, showing tuberculous lesions, especially in the lungs in guinea-pigs and in the liver in rabbits. In the third and fourth series, however, even when these animals died, their organs contained no tubercles nor any bacilli.

These investigators have not succeeded in permanently domesticating the bird-bacilli in the rabbit and guinea-pig, still less in developing from it the bacillus of human tuberculosis. They have also endeavored to determine whether it were possible to vaccinate the dog against human tuberculosis by frequently inoculating him with bird-tuberculosis. Several dogs experimented upon for months received intra-venous injections of the bacilli of bird-tuberculosis; but when they were subsequently subjected to an intra-venous or intra-peritoneal injection of the bacilli of human tuberculosis they all died with the same lesions presented by a control-animal. As an outcome of their experiments, Straus and Gamaleia are led to believe in the non-identity of bird-tuberculosis and the tuberculosis of man.

MM. CADIOT, GILBERT, and ROGER presented a paper on "Human and Bird-Tuberculosis." They first described the appearance of bird-tuberculosis, and stated that it presented itself as caseous masses and granulations, more or less extensive and occupying the liver, spleen, and peritoneum—the intestines presenting ulceration, and in this case the evacuations containing bacilli, thus explaining the mode of infection in, and the origin of, certain epidemics. In hens tubercles are histologically constituted of a mass of epithelioid cells, the central portion of which becomes vitreous; while in pheasants these epithelioid cells are surrounded by connective tissue that undergoes amyloid degeneration; in all these lesions the bacilli present the same appearance and the same reactions to stains as do those of human tuberculosis.

Cadiot, Gilbert, and Roger have also experimented to determine the relation between the tuberculosis of birds and that of mammals. Two series of experiments were conducted. In the first bird-tuberculosis was studied. The virus of bird-tuberculosis injected into the veins and peritoneum of hens produced lesions similar to spontaneous or primary tuberculosis; the same virus injected into the peritoneum of rabbits resulted in a general eruption of visceral tuberculous granulations; the same injections made into guinea-pigs afforded variable results. Twenty-four guinea-pigs each received a peritoneal injection; thirteen presented no appreciable lesion; in seven localized visceral granulations were found; in each of five a caseous abscess was found at the inoculation-point.

In another series two guinea-pigs were inoculated with virus obtained from a case of pheasant-tuberculosis. In both, generalized tuberculosis resulted, the tuberculous products of which were inoculated into another series of guinea-pigs, and this was repeated until the tuberculous products had passed through three series of animals, when it was found that this bird-tuberculosis, by passing through three series of mammals, had lost the specific properties of bird-tuberculosis, and was no longer destructive to birds.

In the second group of experiments forty hens were inoculated with human tuberculous virus and none died; two were still living; while of the remaining thirty-eight, which were killed, thirty-three presented no lesion at autopsy, while in the remaining five, small, transparent, tuberculous granulations were found, evidently identical with human tubercles, as they induced disease in guinea-pigs; in another case, the virus was so much transformed that its inoculation into another hen resulted in disease.

MM. COURMONT and DOR, of Lyons, read a communication on "Bird-Tuberculosis," discussing the probability of its bacillus being only a variety of the bacillus of human tuberculosis. They conducted two sets of experiments. On the one hand, they inoculated hens with mammalian tuberculosis by the subcutaneous method and also by the digestive tract; while on the other hand, rabbits and guinea-pigs were inoculated with bird-tuberculosis. The conclusions arrived at are: that the hen is not absolutely refractory to human tuberculosis; and that inoculation by the digestive tract is much less certain than inoculation by the subcutaneous method; also that the bacillus of human tuberculosis can be propagated in hens by subcutaneous inoculations. Courmont and Dor also believe that when bird-tuberculosis has lost its special influence or character by passing through mammals, it retains the faculty of producing general tuberculosis in the rabbit; but this same virus after a single passage through a hen loses all its peculiar properties toward mammals.

DR. HÉRICOURT, of Paris, related that he had treated 56 cases of tuberculosis with injections of the serum of dogs' blood. He divided his observations into two groups: one included those who had reached the third stage of the disease; in these the treatment had no influence whatever; in the second group, composed of cases of tuberculosis in the second stage, advanced bone-tuberculosis, facial lupus, etc., a remarkable change had taken place, manifested by improvement in the digestion and diminution in the number of bacilli in the sputum, while an absolute cure was only observed in cases at the very beginning of the disease, when no bacilli could be found in the sputa.

DR. LANDOUZY presented a communication on "Tuberculosis of Newborn Children." In the category of newborn, Dr. Landouzy included all children between one day and two years old. He maintained that deaths from tuberculosis constitute a large part of the mortality in the newborn, as shown by the statistics of the Tenon Hospital in Paris—statistics the data of which have been verified by autopsy. Dr. Landouzy insisted that the community ought to be taught the ease with which children are infected with tuberculosis, especially by the digestive tract, even when not predisposed by heredity.

PROF. SEMMOLA, of Naples, read a paper on "The Treatment of Pulmonary Tuberculosis by the Combined Action of Iodoform and Injections of the Serum of Dogs' Blood." He stated that during the preceding eleven years he had obtained good results from the administration of small, frequently repeated doses of iodoform, given by the mouth. For several months he had employed the method of injection of the serum of dogs' blood recommended by MM. Richet and Héricourt, with such favorable results as to encourage him to continue the method, at the same time combining it with the internal administration of iodoform in small, frequently-repeated doses.

DR. VIGNAL next read a paper on the "Heredity of Tuberculosis," being the outcome of laboratory experiments. These experiments were conducted as follows: a number of guinea-pigs were inoculated with fragments of fetal organs or of organs taken from newborn animals the mothers of which were definitely tuberculous.

A second group of guinea-pigs was inoculated with fragments of placenta, macerated, as in the first instance, in a ¾ per cent. salt solution; while a third group was given injections of sputum and fragments of organs obtained from the mothers.

The results were negative as to the transmission of tuberculosis from the mother to the fetus; for, while all the guinea-pigs that received fragments of sputa and organs from tuberculous mothers became tuberculous and died, twenty-four guinea-pigs inoculated with organs obtained from children born of tuberculous mothers and eighteen guinea-pigs that had been inoculated with fragments of placenta remained normal.

In another series of experiments an effort was made to ascertain whether tuberculosis could be directly transmitted to the fetus by the mother. For this purpose an injection of Koch's bacillus was made into the peritoneum of five pregnant guinea-pigs. The liver and spleen obtained from the products of conception were inoculated into nineteen other guinea-pigs, all of which remained non-tuberculous. Several that were killed five months later presented not the slightest trace of tuberculosis. Vignal concludes that instead of being frequent, tuberculous heredity, on the contrary, seems to be very rare.

DR. HUTINEL, of Paris, in connection with the same question, stated that, according to his experience, congenital tuberculosis is very rare; for out of a series of 252 autopsies on children, in only 8 had he found tuberculous lesions, the age in three varying from five to six and seven months, the youngest being forty-one days old, and in none does he feel justified in stating that the tuberculosis was congenital. In the second year, however, he finds that one-third of the children dying present tuberculous lesions, and that this propertion increases still more in the third and fourth year.

Another argument in favor of the tuberculosis not being congenital is that of 18,000 newborn city children who are annually sent to the country through the care of public charitable institutions, not more than 20 tuberculous children have ever been met.

The conclusion to be drawn is that all children born of tuberculous parents are not tuberculous, but constitute subjects favorable for the development of this constitutional disease.

DR. BERNHEIM presented the following conclusions: That there is no such thing in tuberculosis as heredity of the tuberculous germ, and that the predisposition to the development of tuberculosis is not greater in the offspring of tuberculous parents than in those born of individuals suffering with any other constitutional disease; finally, that *tuberculosis is always transmitted by contagion.*

DR. JACOBI, of New York, stated that he was the first, over twenty years before, to present a case of congenital tuberculosis.

DR. KIRMISSON read a paper on "The Treatment of Tuberculous Peritonitis by Means of Injections of the Serum of Dogs' Blood." The patient was a girl, three years old, with ascites, for the relief of which puncture was performed. The liquid again accumulating, laparotomy was resorted to. A large number of tuberculous granulations were found all over the visceral and parietal layers of the peritoneum. After carefully washing out the peritoneal cavity, the abdomen was closed, but a few days later the liquid had again collected. Dr. Kirmisson then proceeded to make injections of the serum of dogs' blood. Soon after, all induration of the abdomen and the ascites completely disappeared.

DR. PINARD also read a communication on "The Treatment of Weak Newly-born Children with Injections of the Serum of Dogs' Blood." Two children, both born before term, of mothers who had reached the last stage of the tuberculosis, and who died soon after confinement, were given injections of the serum of dogs' blood with great benefit. Encouraged by the favorable results obtained, Pinard made injections of the serum of dogs' blood in all children that from whatever cause weighed less than four pounds. In seventeen children the results were so satisfactory as to have stimulated Dr. Pinard to employ this method in all instances in which a considerable weakness is present at birth.

DR. BERTIN, of Nantes, insists that the goat is refractory to spontaneous tuberculosis, and that the economy of this animal contains a substance that is a protective against tuberculosis.

DR. BERNHEIM stated that of forty-eight goats on which he had performed autopsies he had found tuberculous lesions in none, and that he had never been successful in inoculating a goat with tuberculosis.

(*To be continued.*)

CORRESPONDENCE.

THE POWER OF WILL IN DISEASE.

To the Editor of THE MEDICAL NEWS,

SIR: On reading your editorial on "The Power of Will in Disease," in THE MEDICAL NEWS of June 27th, a case came to my mind that may be cited in illustration of the correctness of your remarks.

While I was resident house-physician in the German Hospital in London, a girl, about twenty-two years old, came to the out-patient department, accompanied by her mother and walking with much difficulty on crutches. She stated that she was unable to stand without support, not to mention walking; that this condition had existed for a long time, for months if not for years, and that she had gone the rounds of pretty nearly all the London hospitals without deriving any benefit. Her condition,

in fact, was continually becoming worse. At first sight I judged the case to be one of hysterical paraplegia and told the girl to wait until I had disposed of the other patients, when I would examine her case more thoroughly. After the other patients had been attended to, I made a few necessary inquiries and examined the feet and legs, and was convinced that my diagnosis was correct. I thereupon applied the faradic current to each leg for a few minutes, prescribed some embrocation (the nature of which I have entirely forgotten), and told the girl to report in a fortnight.

When she returned she came without crutches, walking with perfect ease, and exceedingly happy and grateful for the improvement. I have not heard of her since, having left the hospital some years ago, but as this occurred about three-quarters of a year before I left, I presume that the cure lasted at least that long, as she would otherwise probably have returned, having been so much benefited the first time.

As an epicrisis to this note I should like to offer the following: This case had, no doubt, been correctly diagnosticated at the other hospitals, but had possibly not received the necessary *sympathy* at the hands of the physicians; for we all know what a *crux medicorum* hysteria often proves. Then some good friend may have told the girl to try the German Hospital; that the physicians there were very clever people. Probably favorably prepossessed she came, and on finding that she received more attention than had been given her in the other over-crowded places, possibly with a lot of students worrying over the cases, she conceived the idea that her disease could be cured, and the successful termination was, in fact, the direct outcome of her own (subjective) conviction. I am, etc.,

F. A. Philippi, M.D.

Nieheim, Westphalia.

TYPHOID FEVER AND INSANITY.

To the Editor of The Medical News,

Sir: The recent reports in The Medical News by Dr. E. E. Graham and Professor H. A. Hare of cases of typhoid fever complicated by insanity are certainly of great interest.

There is, however, a criticism which I wish to make for the sake of accuracy.

Mercier (*Sanity and Insanity*, p. 140) says: "There are only two causes of insanity—*heredity* and *stress*." This broad definition, it seems to me, entirely covers the ground. Everyone has more or less tendency, on account of heredity, to become insane. The greater this tendency, the less the stress of outer circumstances will there be required to produce insanity, and *vice versa*.

Cases have been reported by Wood, Osler, and others in which insanity has developed in the course of or during convalescence from typhoid or other fevers and also after injuries and surgical operations. The operative causes producing insanity, common to all these physical processes and conditions, are malnutrition, exhaustion and irritation of the cerebral structure. Now, ordinarily the cerebral disturbance induced by these physical ailments does not provoke insanity, because there is not sufficient cerebral instability. But let a person with an exceedingly unstable nervous organization be attacked with dysentery, typhoid fever or pneumonia; then insanity will be apt to develop as a complication or a sequel. This insanity will, in all likelihood, be of that *form* to which the person is predisposed.

In Dr. Graham's case, for instance, it is very probable that a severe surgical operation, an attack of one of the severe fevers (other than typhoid), or any great emotional disturbance would have induced insanity. The heredity existed. The fever was sufficient stress.

In a certain sense, it must be admitted that it is correct to speak of insanity as a complication or a sequel of any of these physical processes. But I would call attention to and emphasize the fact that when insanity occurs in this connection, these various physical diseases simply act as the exciting causes. It would therefore be also entirely correct to speak of typhoid fever as the exciting or determining cause of insanity, or to say that insanity was induced by typhoid fever.

Theodore Diller.

KNIFE-BLADE IN THE BRAIN.

To the Editor of The Medical News,

Sir: The report in The Medical News of July 25th of a remarkable case in which a knife-blade was carried in the brain for years after its entrance, recalls a peculiar and somewhat similar case presented to the class of medical students in the University of Louisville in the winter of 1849–50, at the medical clinics of Prof. Elisha Bartlett, at the Louisville City Hospital. A man was brought into the medical wards for an undiagnosticated brain-trouble. He appeared insane, could give no history of himself, did not make any complaint, nor, as I remember, did he talk at all.

The cerebral disturbance was evident enough, but its cause could not be determined. Examination of the body revealed many scars (principally over the chest) which appeared to have been a result of knife-stabs and cuts. There was also above the external angle of the left eye a festered spot, so small that it was not regarded as of any significance.

In the course of a few weeks the man died. On post-mortem examination a piece of a dirk knife blade from two to three inches long, I think, was found in the left anterior lobe of the brain, having penetrated the orbital process of the frontal bone and having been broken off, entering in at the festered spot, which proved to be the orifice of a sinus communicating with a deep abscess formed around the blade of the knife in the brain. How long the knife-blade occupied this situation could not be stated, but supposing that the injury was inflicted at the same time as that to which the scars were due, it must have been some months, as the cicatrices appeared to be old.

I do not know if this case was ever published and I write exclusively from memory; my record may not be exact, but the history in more perfect form ought to be found in the old records of the Louisville City Hospital.

Very respectfully, Virgil McDavitt, M.D.

Quincy, Ill.

DuBois-Reymond, of Berlin, has been awarded the Gold Medal of Science.

NEWS ITEMS.

The Association of American Physicians will hold its sixth annual meeting, in connection with the second Congress of American Physicians and Surgeons, at Washington, D. C., September 22, 23, 24 and 25, 1891.

The following program has been formulated:

TUESDAY, SEPTEMBER 22D.

Session of the Association, 10 A.M.

President's Address, by Dr. William Pepper, of Philadelphia.

General business, reports, etc.

Discussion on the Treatment of Visceral Tuberculosis by Koch's Method. Reports by Dr. F. P. Kinnicutt, of New York; Dr. Harold C. Ernst, of Boston; Dr. William Osler, of Baltimore; Dr. J. H. Musser and Dr. J. P. C. Griffith, of Philadelphia.

The Climate of Southern California for Respiratory Diseases: a Preliminary Paper, by Dr. Norman Bridge, of Los Angeles.

Experimental Studies on the Causes of the Localization of Pulmonary Phthisis and certain other Infectious Diseases in the Lungs, by Dr. J. W. Roosevelt, of New York.

Session of the Congress, 3 P.M.

Conditions Underlying the Infection of Wounds, including a Discussion of Disinfection with reference to the Treatment of Wounds, of the Relation of Bacteria to Suppuration, of the Resistance of Tissues to the Multiplication of Bacteria, and of the Effects of Antiseptic Agents on Wounds. *Referee*, Dr. William H. Welch, of Baltimore. *Co referee*, Dr. Roswell Park, of Buffalo.

The discussion will be adjourned, if necessary, until Friday afternoon.

WEDNESDAY, SEPTEMBER 23D.

Session of the Association, 10 A M.

Discussion on the Remote Results of the Removal of the Ovaries and Tubes. *Referee*, Dr. William T. Lusk, of New York. *Co-referee*, Dr. Wharton Sinkler, of Philadelphia.

Nerve-stretching in Inveterate Cases of Trigeminal Neuralgia, by Dr. James Stewart, of Montreal.

On the Diseases of the Kidney, popularly called "Bright's Disease," by Dr. F. Delafield, of New York.

Note on the Recognition of Certain Cases of Epilepsy, accompanied by Albuminuria, which might be mistaken for Cases of Uremic Convulsions, by Dr. James Tyson, of Philadelphia.

Bradycardia in Acute Articular Rheumatism, by Dr. I. E. Atkinson, of Baltimore.

Session of the Congress, 3 P.M.

The Late Manifestations of Syphilis. *Referee*, Dr. Phineas S. Conner, of Cincinnati. *Co-referee*, Dr. Abner Post, of Boston.

The President's Address will be delivered in the Lecture Hall of the National Museum at 8 P.M., and will be followed by the reception of the President from 9.30 to 12 P.M.

THURSDAY, SEPTEMBER 24TH.

Session of the Association, 10 A.M.

Discussion on the Relations between Arterial Disease and Visceral Changes. *Referee*, Dr. George L. Peabody, of New York. *Co-referee*, Dr. W. T. Councilman, of Baltimore.

Intestinal Perforation in Typhoid Fever, by Dr. R. H. Fitz, of Boston.

The Relation of Drinking-water to Disease, by Dr. Henry P. Walcott, of Cambridge.

A Contribution to the Pathology of Pernicious Anemia, by Dr. J. P. Crozer Griffith and Dr. Charles W. Burr, of Philadelphia.

On Changes in the Red Blood-corpuscles in the Pernicious Anemia of Texas Cattle Fever, (by invitation) by Dr. Theobald Smith, of Washington.

Session of the Congress, 3 P.M.

Fibroid Processes (Chronic Interstitial-Inflammation Scleroses): Their Pathology and Etiology, with Special Reference to the Influence of Diathesis and Heredity. *Referee*, Dr. A. L. Loomis, of New York City. *Co-referee*, Dr. William Osler, of Baltimore.

Dinner, conjointly with the American Surgical Association, in honor of foreign guests, at the Arlington Hotel, at 8 P.M.

FRIDAY, SEPTEMBER 25TH.

Session of the Association, 10 A. M.

The Condition and Prospects of the Library of the Surgeon-General's Office, and its Index Catalogue, by Dr. John S. Billings, of Washington.

Sequel to a Case of Slow Pulse (Purdy), by Dr. D. W. Prentiss, of Washington.

Report of Autopsy, by Dr. Robert T. Edes, of Washington.

Grave Forms of Purpura Hemorrhagica, by Dr. J. H. Musser, of Philadelphia.

Pathological Histology of Acute and Chronic Appendicitis, by Dr. William F. Whitney, of Boston.

The Treatment of Typhoid Fever by Systematic Cold Bathing, by Dr. James C. Wilson, of Philadelphia.

Concluding business.

Session of the Congress, 3 P.M.

If necessary, the discussion on the "Conditions Underlying the Infection of Wounds," etc., will be resumed.

Drs. James G. Glover and William M. Ord, of London; Drs. McCall Anderson and W. T. Gairdner, of Glasgow; Dr. J. Battey Tuke, of Edinburgh; Professor Curschman, of Leipsic; Professor Kühne, of Heidelberg; and Dr. Löwenberg, of Paris, have already accepted the invitation of the Association to attend the Congress, and will be the guests of the Association, participating in the discussions of the papers read before it.

The Association will hold its meeting in Hall No. 1 of the Grand Army Building, 1412 and 1414 Pennsylvania Avenue, and in the Main Hall of the same building the meetings of the Congress will be held.

Members of this Association are *ipso facto* members of the Congress, and as such are expected to register. Parlors 1 and 2 in the Arlington Hotel will be provided for that purpose, from which the mail of the members and guests will be distributed, and at which the city residence of each member or guest can be ascertained. The registration fee is five dollars.

A copy of the Transactions of the Congress will be sent to each person who may register, and only those who

may register, invited guests, and ladies accompanying them, will be admitted to the reception of the President.

Dr. Samuel C. Busey is the representative of the Association on the Committee of Arrangements, of which he is Chairman.

The American Gynecological Society will hold its sixteenth annual meeting at Washington, D. C., on September 22, 23, and 24, 1891. The following program has been arranged:

Tuesday, September 22d. Address of Welcome; by Dr. Joseph Taber Johnson, of Washington.

The Advantages of Mixed Anesthesia in Gynecological Surgery; by Dr. John C. Reeve, of Dayton, O.

Concealed Accidental Hemorrhage during Labor; by Dr. Henry C. Coe, of New York.

Diffuse Adenoma of the Uterine Body; by Dr. James R. Chadwick, of Boston.

The Influence of Season on Recurrent Pelvic Inflammations; by Dr. Frank P. Foster, of New York.

The Therapeutic Aspect of Some Ovarian Disorders; by Dr. Edward W. Jenks, of Detroit.

Insanity following Laparotomy; by Dr. J. M. Baldy, of Philadelphia.

Vaginal Hysterectomy by Morcellement: Technique and Indications for Operation; by Dr. Samuel Pozzi, of Paris, France.

A Clinical Study of Primary Carcinomatous and Sarcomatous Neoplasms between the Layers of the Broad Ligament, with Report of Cases; by Dr. Joseph E. Janvrin, of New York.

The Present and Improving Status of Cæsarean Surgery; by Dr. Robert P. Harris, of Philadelphia.

Unique Case of Multiple Neuro-lipomata following Laparotomy; by Dr. H. Marion Sims, of New York.

Wednesday, September 23d. President's Address.

The Treatment of Cancer of the Cervix Uteri by High Amputation; Second Series of Cases, with Additional Report on the First Series; by Dr. William H. Baker, of Boston.

The Advantages of Delivery in the Left Lateral Posture; by Dr. Henry J. Garrigues, of New York.

The Influence of Imperfect Development as a Cause of Uterine Disease; by Dr. W. Gill Wylie, of New York.

The Technique of Vaginal Fixation of the Stump in Abdominal Hysterectomy; by Dr. Henry T. Byford, of Chicago.

Can we Avoid Mural Abscesses and Ventral Herniæ after Laparotomy? by Dr. Horace T. Hanks, of New York.

Some Clinical Testimony as to the Ultimate Results of Removal of the Uterine Appendages; by Dr. Thaddeus A. Reamy, of Cincinnati.

Indications for Abdominal Section in the Treatment of Puerperal Pelvic Inflammations; by Dr. R. B. Maury, of Memphis, Tenn.

A Study Relative to the Functions of the Reproductive Organs in American Indian Women; by Dr. Andrew F. Currier, of New York.

The Immediate Closure of Laceration of the Cervix; by Dr. Cornelius Kollock, of Cheraw, S. C.

The Conservative Treatment of Pelvic Tumors and Diseases; by Dr. Eugene Gehrung, of St. Louis.

The Anatomical Relations of the Lacerated Perineum to the Mechanics of its Causation; by Dr. Edward Reynolds, of Boston.

Thursday, September 24th. In Memoriam—Dr. Fordyce Barker; by Dr. James R. Chadwick, of Boston.

Ureteritis in the Female; by Dr. Matthew D. Mann, of Buffalo.

The Surgical Treatment of Retroversion and Prolapse of the Uterus; by Dr. Paul F. Mundé, of New York.

A Paper; by Dr. Theophilus Parvin, of Philadelphia.

Series of One Hundred Laparotomies; My Mistakes and Failures; by Dr. A. Palmer Dudley, of New York.

Laparotomy in Trendelenburg's Posture, with Exhibition of a New Operating-table; by Dr. Clement Cleveland, of New York.

The Electrical Treatment of Uterine Fibroids in England; by Dr. George Keith, of Brooklyn.

Diabetes Mellitus Gravidarum; by Dr. Henry D. Fry, of Washington.

A Successful Porro Operation; by Dr. R. Stansbury Sutton, of Pittsburg, Pa.

An Argument against the Stem-pessary, or so-called Drain-tube; by Dr. Egbert H. Grandin, of New York.

American Ophthalmological Society.—The twenty-seventh annual meeting of the American Ophthalmological Society will be held this year, beginning on Wednesday, the 23d of September, at the Arlington House, Washington, D. C.

Titles of the following papers to be read at the meeting have been received, and will take precedence on the bulletin:

Gouty Retinitis—Neuro-retinitis and Chorio-retinitis; History of Case of Brain Tumor with Autopsy; The Operative Treatment of Detachment of the Retina by Schöler's Method, with Report of Five Cases; by Dr. C. S. Bull.

The Use of Vaselin in Gonorrheal Conjunctivitis; by Dr. F. M. Wilson.

Case of Orbital Traumatism followed by Immediate Monocular Blindness due to Fracture of the Foramen Opticum; by Dr. P. A. Callan.

The Significance of Macular Changes in Advancing Myopia; by Dr. H. Derby.

Glaucoma after Extraction of Cataract; by Dr. F. Buller.

The Blind of New York City; by Dr. H. S. Oppenheimer.

Additional Experiments to Determine the Lesion in Quinine Blindness; A Case of Elephantiasis of the Eyelid; A Case of Acute Glaucoma occurring in an Eye with Coloboma of the Iris and Supernumerary Pupils (the first two papers illustrated by photo-micrographs and microscopic slides); by Dr. G. E. de Schweinitz.

A Clinical Study of the Ocular Symptoms found in the so-called Mongolian Type of Idiocy; by Dr. C. A. Oliver.

Extraction of Foreign Bodies from the Vitreous; by Dr. E. E. Holt.

Contributions to the Study of Heterophoria; by Dr. Swan M. Burnett.

Report of Cases of Cataract Extraction; by Dr. D. Webster.

Extraction of Foreign Bodies from the Interior of the Eyeball; by Dr. S. B. St. John.

A Partially Bony Growth of Orbit—Removal—Recovery; by Dr. B. L. Milliken.

Clinical Studies in Scotoma Scintillans; by Dr. D. De Beck.

Retinal Vessel Observations in Contusion of the Brain; by Dr. A. G. Heyl.

Ulcerative Keratitis in the Negro; Eye Complications in La Grippe; by Dr. J. A. Andrews.

Subnormal Accommodative Power in Young Persons a not infrequent Cause of Asthenopia; A Case of Successful Skin-grafting upon the Eyelid by Thiersch's Method; Supplementary Note to the Case of Useful Vision maintained by the Aid of a Totally Dislocated Lens, heretofore reported to the Society; by Dr. S. Theobald.

The Occurrence, Prevention, and Management of Prolapse of the Iris in Extraction of Cataract; Demonstration of a Roller Forceps for Pressing Out Trachomatous Granulations according to the Mangle Principle; by Dr. H. Knapp.

Recurrent Inflammation of Tenon's Capsule of both Eyes in connection with Mercurial Poisoning; Phlegmon of the Orbit in the Newborn; Gangrene of the Skin of both Lids in both Eyes; by Dr. C. J. Kipp.

On the Measurement of Simple and Compound Lenses; by Dr. L. Howe.

Routine Syringing-out of Cortical Matter in Cataract Extraction as Illustrated in 100 Cases; by Dr. J. A. Lippincott.

Two Cases of Intense Vertigo produced by an Attempted Correction of Astigmatic Refraction; by Dr. George Strawbridge.

The American Surgical Association will hold its annual meeting at Washington, D. C., September 22, 23, 24, and 25, 1891. The contemplated program includes discussions upon the following subjects:

Present Status of Brain-Surgery; by Dr. D. Hayes Agnew, of Philadelphia.

Report of the Committee on the Results which Should be Considered as Satisfactory, of Treatment of Fractures of the Shaft of the Femur; by Dr. Stephen Smith, of New York.

Conditions Underlying the Infection of Wounds: including a discussion of Disinfection with reference to Treatment of Wounds; of the Relation of Bacteria to Suppuration; of the Resistance of Tissues to the Multiplication of Bacteria; and of the Effects of Antiseptic Agents on Wounds.

Aseptic and Antiseptic Details in Operative Surgery; by Dr. A. G. Gerster, of New York.

Surgical Treatment of Injuries and Diseases of the Vertebral Column; by Dr. J. William White, of Philadelphia.

On Retro-peritoneal Abdominal Tumors, and Especially Those Involving the Kidney, by Dr. A. Vander Veer, of Albany, N. Y.

The Late Manifestations of Syphilis.

Recurrence of Cancer of the Breast; by Dr. Frederic S. Dennis, of New York.

The Treatment of Tuberculosis of Bones and Joints by Parenchymatous and Intra-articular Injections; by Dr. Nicholas Senn, of Milwaukee, Wis.

Fibroid Processes (Chronic Interstitial Inflammation, Scleroses): Their Pathology and Etiology, with Special Reference to the Influence of Diathesis and Heredity.

Treatment of Fractures Involving the Elbow-joint; by Dr. Lewis A. Stimson, of New York.

Fractures Involving Upper Third of Femur, Exclusive of Neck; by Dr. Oscar H. Allis, of Philadelphia.

Thoracic Surgery; by Dr. DeForrest Willard, of Philadelphia.

A Case of Diffuse Hypertrophy of the Breasts, with Photographs; by Dr. C. P. Porter, of Boston, Mass.

Fractures of the Bones which form the Elbow-joint, and their Treatment; by Dr. Levi C. Lane, of San Francisco, Cal.

Old Unreduced Luxations of Elbow; by Dr. Lewis A. Stimson, of New York.

The Study of a Case of Hemiplegia with Aphasia, following Ligature of Common Carotid Artery; by Dr. J. Ewing Mears, of Philadelphia.

Investigation of Pistol-shot Wounds of the Skull, and their Treatment; by Dr. E. H. Bradford, Boston, Massachusetts.

The Result of some Experiments in the Filling of Cavities in Bones following Operations for Caries; by Dr. E. H. Bradford, of Boston, Mass.

The American Otological Society will hold its twenty-fourth annual meeting, September 22, 1891, at Washington, D. C. Titles of the following papers to be read at the meeting have been announced:

Some Partially Successful Attempts to Promote the Healing of Old Perforations of the Tympanic Membrane; by Dr. S. Theobald.

An Unusual Form of Dislocation of the Malleus Handle; by Dr. S. Theobald.

Some Unusually Severe Cases of Mastoid Disease in Influenza; by Dr. H. Knapp.

Three Cases of Suppurative Otitis with Complications and One Death; by Dr. F. M. Wilson.

A Case of Suppuration, Exostosis, and Otitic Epilepsy—Trephining followed by Fatal Septic Meningitis; With a Consideration of Other Specimens, Illustrating the Avenues of Communication of Otitis to the Brain; by Dr. B. Alexander Randall.

Notes on the Use of the Leiter Coil in the Early Stage of Mastoid Disease; by Dr. Gorham Bacon.

A paper (title not yet announced); by Dr. C. J. Blake.

Acute Suppuration of the Middle Ear; Meningitis; death; autopsy; no involvement of the Temporal Bone; by Dr. J. M. Ray.

A Concluding Communication on the Anatomy of the Elephant's Ear; by Dr. Huntington Richards.

Membership in the American Medical Association is open to members of any State or local Medical Society entitled to send delegates to the Association who will send to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues. Attendance as a delegate at an annual meeting of the Association is not necessary in order to obtain membership. The weekly journal of the Association is forwarded regularly to members.

REPORT OF FIVE SURGICAL CASES FOLLOWING GUNSHOT INJURY.

BY PAUL R. BROWN,
CAPTAIN AND ASSISTANT SURGEON IN THE UNITED STATES ARMY.

CASE I.—On May 7, 1886, I was ordered to Nogales, Arizona, to see Corporal E. S., who on May 3d, in the Sierra Pinita, Sonora, Mexico, had been shot in a skirmish with hostile Apaches. This man rode horseback eight miles on the same day, and on the day following he was carried in a wagon without springs a distance of twenty-eight miles. On the day of his removal, cold-water applications and a side splint were put on his thigh by Dr. Purdy, a civilian physician from Nogales. Except a few injections of morphine, he received no other treatment until my arrival in Nogales on the evening of May 7th. I found him in a room without any window, a door opening into the corridor being the only means of ventilation. I made a cursory examination of his wounds, but as he was suffering greatly, deferred my systematic examination until the following morning. The knee and foot were greatly swollen and inflamed. As he had a temperature of 104.8°, and was suffering for want of fresh air, I had his bed moved into an open shed, much to his comfort. Ice-water applications were placed upon his knee and foot, and I gave orders to have them constantly renewed during the night. On the morning of May 8th I made a careful examination of his wounds, and found that he had been hit by a bullet, caliber 45, that had entered the right knee-joint a little above the middle of the internal edge of the patella. The projectile passed through the internal condyle of the femur, then downward through the head of the tibia, and emerged from the leg about the center of the middle third on the internal lateral aspect. After emergence from the leg it still continued its course downward and forward, and penetrated the left foot on its superior aspect, finally lodging between the second and third metatarsal bones, fracturing, but not comminuting them. The internal condyle of the femur and the head of the tibia were both badly shattered. I considered amputation to be necessary, although I had grave doubts as to the result, both on account of the intense inflammatory action, and also from the length of time that had elapsed since the injury was received, and the fact that the amputation must necessarily be "intermediate." Accordingly, at 11 A.M., assisted by Drs. Terrill and Purdy, I proceeded to amputate the thigh in the lower third by a modified antero-posterior flap operation. A. C. E. mixture was used as the anesthetic, and Esmarch's tourniquet was employed to restrain hemorrhage. Four silk ligatures were applied, but even then there was free parenchymatous oozing from the flaps, which was instantaneously arrested by hot water at a temperature of 150° F.

Since 1878 I have habitually used hot water, never under 150° F., to check parenchymatous hemorrhage following the use of Esmarch's tourniquet, and I have invariably tested the temperature, before using, with a small chemical thermometer. In the Philadelphia *Medical Times* of August 30, 1879, page 569, is a brief article communicated by me in reference to this use of hot water. Dr. Charles T. Hunter, at that time Demonstrator of Anatomy in the University of Pennsylvania, in an article published in the same journal, "On the Use of Hot Water as a Hemostatic in Surgery," (November 22, 1879, page 91), says that this high temperature of the water "is a matter of some surprise, for it is reasonable to suppose that a degree of heat sufficient to coagulate albumin would scald living tissues and excite a grade of inflammatory action incompatible with union by first intention." Facts are stronger than suppositions. I have used hot water, never less than 150°, very nearly a hundred times since December, 1878, to restrain hemorrhage, and not once have I seen it give rise to even the slightest inflammatory action.

A rubber drainage-tube was then inserted at the angle of the wound, the flaps irrigated with sublimate solution 1:1000, and united by deep and superficial silk sutures. The amputation-wound was dusted with iodoform, covered with sublimate gauze, and the stump wrapped in absorbent cotton and snugly bandaged. The foot was then examined, and although the ball could be located with the Nélaton probe, it was so tightly wedged between the bones that I did not deem it advisable at that time to remove it, as the patient had been sufficiently long under the anesthetic. The foot was then irrigated and dressed. No attempt was made to make the operation an antiseptic one, although the parts, hands, instruments, etc., were made thoroughly clean before the operation. On May 10th S. was placed on the cars and transported forty-nine miles, and then seven miles in an ambulance to Fort Huachuca. Twenty-four hours after the operation I turned the case over to Dr. Terrill, who accompanied him to this post, I being ordered into the field. The dressings were removed on the evening of May 13th on account of some bloody oozing, much sooner than there was any necessity. Union

of the flaps was found to be complete, except where the drainage-tube was inserted. On May 16th the stump was completely healed. On May 22d the bullet in the foot was removed, the wound soon healing. An examination of the knee-joint after the operation showed, in my opinion, that under the circumstances amputation of the thigh was the only justifiable operation, as the internal condyle of the femur and head of the tibia were shattered into a dozen fragments, and all statistics of military surgery to date give a most frightful mortality following excisions of the knee-joint for gunshot fracture, greatly exceeding that of amputations of the thigh in the lower third.

The pathological specimen has been sent to the Army Medical Museum at Washington, D. C., and also a photograph representing the appearance of the stump January 1, 1887.

CASE II.—E. K., twenty-five years old, an American, a miner by occupation, and of good habits and fine physique, on February 19, 1886, while passing through Santa Rosa Cañon, Mexico, was fired upon by hostile Chiricahua Apaches and seriously wounded in two places. One bullet, caliber 45, entered the left knee-joint at the middle of the external lateral border of the patella, just grazing it, and then, passing downward and inward, penetrated the head of the tibia, comminuting it and completely separating from its articulation fully one-half of the head of the internal portion of that bone, and finally lodged underneath the skin four inches below the articulation on the internal lateral aspect of the leg. The second bullet, caliber 44, after passing through the sides of a heavy lumber-wagon, entered the right foot on its external lateral aspect, shattered the cuboid bone, and, passing forward, lodged between the fourth and fifth metatarsals, comminuting them. In spite of these serious wounds, K. succeeded in cutting a mule loose from the wagon, mounted it and rode eight miles to his camp, and then fell from the animal, fainting from shock and loss of blood. His fellow-miners did all they could for him, putting cold-water compresses upon his wounds and giving him laudanum to alleviate his suffering, he requiring nearly a quarter of an ounce at a dose. An irregular practitioner from Moctezuma, Sonora, was summoned, whose principal object seemed to be the removal of the bullets, everything else being of secondary importance. After removal of the ball from the leg he poured pure carbolic acid into the wounds and about them, nearly skinning the man's leg, and finally put on side splints and left him. Within a week the wounds were suppurating freely, small fragments of bone occasionally being discharged. Two months after the injury a small abscess formed on the internal lateral aspect of the thigh, communicating with the initial wound of the knee. Save that above mentioned, he received no surgical treatment until I took charge of the case. As he was rapidly losing flesh and strength from the profuse suppuration, he was sent up from Sonora, riding 110 miles over rough roads, and brought to me for examination on July 23, 1886, five months after the injury. He was very much emaciated, exceedingly weak and nervous, and had a temperature of 101.8°. Three fistulous openings on the inner side of the upper third of the leg were discharging freely, and large, loose fragments of dead bone could be plainly felt with the probe. There were also two fistulous openings in the right foot that were discharging pus, and, upon probing, dead bone could be detected. I urged the necessity of an immediate excision of the knee-joint or an amputation of the thigh, but the patient bitterly opposed both procedures, and left the hospital the same day.

On August 4th he returned and placed himself under my care, still strenuously opposing any capital operation. The knee-joint was ankylosed and the relations of the parts were so much changed from their normal condition that it was virtually impossible to ascertain the magnitude of the lesion. As there was much uncertainty as to the extent of the injury to the knee-joint, I informed the patient that there was a bare possibility of saving his leg by cutting down upon it and removing all dead and carious bone. This I did, on August 6, 1886, taking away three large, loose fragments and chiselling out all that what was necrosed or carious. During the operation it was discovered that the large fragment of the head of tibia detached at the time of the injury, although living, had been entirely separated from its articulation and forced externally and posteriorly, so that it lay behind the fibula and in contact with the external condyle of the femur, being ankylosed to both bones. The operation-wound was irrigated with sublimate solution 1:1000, stuffed with absorbent cotton soaked in the same solution, dusted with iodoform and covered with sublimate gauze. The case progressed favorably for six weeks, the patient's general condition greatly improving. The suppurative discharge was very slight and it began to look as if the leg might yet be saved. But a suspicious redness appeared over the external lateral aspect of the articulation that in a few days culminated in a well-defined abscess, the patient having an evening temperature of 103°. This was freely opened and irrigated with sublimate and the joint carefully examined with a probe, with the result of finding the condyles of the femur in a carious condition. At my earnest solicitation the patient finally consented to permit me to use my own judgment in regard to the case. I decided to cut down upon the knee-joint and perform excision in case the lesion of the femur was not extensive; if it was, to amputate the thigh at whatever point I might find sound bone. The operation was performed on September 7, 1886. Both condyles of the femur were found to be seriously diseased and there were also carious patches fully three inches above upon the lower part of the shaft. Amputation of the thigh about the middle of the lower third was then performed by a modified circular operation. A. C. E. mixture was the anesthetic. Esmarch's tourniquet was used to restrain hemorrhage, and catgut employed for ligatures and sutures. Rubber drainage-tubes were placed in the angles of the wound, the stump irrigated with sublimate

1 : 1000, and the edges of the amputation-wound united by deep and superficial sutures. Iodoform was then dusted on the wound and the stump was wrapped in sublimate gauze and absorbent cotton and very snugly bandaged. Whilst dressings were being applied to the amputation-wound, I cut down upon the lateral external aspect of the right foot and removed the cuboid bone and parts of the forth and of the fifth metatarsals. The wound of the foot was dressed similarly to that of the thigh, and one-half grain of morphine given hypodermatically. The patient's temperature on the morning after the operation was 99.6°, three and two-tenths degrees lower than on the day before, and at no time after the operation did his temperature go above 100.2°. Both stump and foot were dressed on the seventh day. There was no purulent discharge from the stump, the amputation-wound having almost entirely healed by first intention and fully one-half of the wound in the foot had healed in the same manner. The case progressed favorably every way, strict asepsis being observed, and in twelve days after the amputation the stump was entirely healed. The foot healed much more slowly, but on November 1st the patient left the hospital, well and in magnificent condition, with the aid of crutches walking upon the injured foot.

The pathological specimen, which, so far as I know, is unique, has been forwarded to the Army Medical Museum at Washington. It shows what tremendous efforts unassisted Nature sometimes puts forth to repair an injury. That the internal half of the head of the tibia, torn from its articulation with the internal condyle of the femur, should retain its vitality and eventually become completely transposed and ankylosed to the external condyle of the fibula and the posterior surface of the other half of the head of the same bone, seems almost incredible, but such is the fact. I am greatly indebted to Chas. C. Barrows, Assistant Surgeon U. S. A., for valuable assistance rendered me during the last two operations on E. K.

CASE III.—On December 15, 1886, while hunting, Private Martin P. Johnson, Fourth Cavalry, was accidentially shot by a comrade. At the time he was shot, he bled profusely, but his comrades succeeded in stopping the hemorrhage by tightly bandaging his leg. On the same day he was carried to a ranch six miles distant. A messenger was sent to the post and Assistant Surgeon T. S. Mason immediately started back with the messenger, reaching the ranch at 3 A.M. As the hemorrhage was controlled, Dr. Mason, fearing a renewal of the hemorrhage, only made a cursory examination of the wound In five hours he started back with Private Johnson and arrived at the post at 8 o'clock in the evening. Owing to the lateness of the hour, I ordered cold antiseptic lotions to be applied to the ankle during the night. The next morning, after etherizing the patient, I carefully examined the leg and found that the ankle-joint was irreparably injured, the carbine bullet, caliber 45, having entered the left foot just above the os calcis, on its internal lateral aspect, had passed obliquely upward, forward and outward through the tibia and fibula about half an inch above the articulation with the astragalus, comminuting them fully three inches above the joint. The articular surface of the tibia was broken into fragments, and in all probability the main arteries of the leg had been torn across. This was, after operation, found to be the fact. The ankle was badly swollen and inflamed and the wound very offensive in spite of the antiseptic applications. I immediately proceeded to amputate the leg at the upper border of the lower third by the ordinary circular operation. Two ligatures, both of gut, were applied to the anterior tibial and peroneal arteries, the posterior tibial being absent. The edges of the amputation-wound were brought together with gut sutures, after irrigation with sublimate 1 : 1000, then dusted with iodoform and covered with sublimate gauze and the stump wrapped in cotton and firmly bandaged. One-half grain of morphine was then given subcutaneously. The stump was not dressed until the fifth day. There was no purulent discharge, but there had been some oozing of bloody serum. The wound was about two-thirds healed by first intention. The stump was irrigated internally through a drainage-tube, the insertion of which I omitted to mention, with sublimate 1 : 2000, and again dressed as before. The case progressed favorably until the thirteenth day, when there was a slight hemorrhage from a small opening that was still unhealed and the whole stump was inflamed. The inflammation was subdued in twenty-four hours and the case went on uninterruptedly to recovery in a little more than three weeks.

An examination of the amputated leg fully justified the operation, as the tibia and fibula had been broken into fragments, eleven in number, some entirely detached, others nearly in place. The anterior tibial and peroneal arteries had been torn across and decomposition had already commenced in the foot. Any attempt to save the leg would have been worse than useless. In the year 1877 I had a case almost identical, save that the arteries were not injured. An attempt was made to save the leg, but after seven or eight months of fruitless labor on my part and a great deal of suffering on the part of the patient, I was compelled to amputate in the lower third. A special report of the case, and also the morbid specimen, were at the time forwarded to the Surgeon-General's Office.

CASE IV.—Private W. R., Company C, 17th U. S. Infantry, aged forty-seven, of Irish birth, was admitted into the post hospital, Fort D. A. Russell, Wyoming, on July 21, 1887, "suffering from a severe penetrating gunshot wound of the right shoulder, with injury to the head of the humerus, the ball passing through the shoulder-joint downward and backward, probably lodging under the scapula. The missile was a 45-caliber rifle bullet." Nothing in the way of operation had been attempted prior to my taking charge of the case in November

1888. At that time the arm and shoulder were honeycombed with sinuses which were discharging profusely, and rapidly draining the vitality of the patient. For over fifteen months he had been in bed, and this also had greatly weakened his constitution. On account of the swollen and indurated condition of the shoulder it was virtually impossible to make a precise diagnosis, but after careful probing I decided that there was necrosis of the coracoid process and glenoid cavity, and of the head and shaft of the humerus to at least two inches below the surgical neck. From time to time small fragments of bone had been discharged from the various sinuses. I then determined that after getting the patient in as good general condition as possible, I would cut down upon the shoulder-joint, remove the necrosed bone from the scapula, and exsect the head and as much of the shaft of the humerus as might be found diseased. By opening some of the sinuses and the daily irrigation of all of them with antiseptic solutions, the amount of purulent discharge was greatly reduced. The improved condition of the patient soon demonstrated the advisability of this procedure. On November 19, 1888, a year and very nearly four months after the injury, I proceeded to carry out the various steps of the operation above mentioned. Ether was used as the anesthetic, and Esmarch's tourniquet as the means of controlling hemorrhage. The first incision was about five inches in length, commencing at the superior edge of the glenoid cavity of the scapula and extending down the middle of the external aspect of the arm. Another incision of three inches in length was now carried across the upper edge of the glenoid cavity and at a right angle with the first one, the two incisions forming a T. These incisions fully opened up the joint. As ankylosis had taken place, to break up the adhesions with very little force I lifted up the arm, when to my surprise the humerus broke off at about the middle of shaft, showing a very much more extensive necrosis than I had anticipated, and adding greatly to the difficulty of the operation and to the risk to the patient. I then cleared the upper fragment of the shaft, disarticulated the head of the humerus and curetted the edges and bottom of the glenoid cavity, removing nearly the half of the coracoid process of the scapula. Then, after lengthening the primary incision, I exsected the lower fragment of the shaft of the humerus at a point four inches above the elbow-joint. During the operation, hemostatic forceps were applied to the spirting arteries, for which, later on, catgut ligatures were substituted. To restrain capillary hemorrhage the wounds of operation were douched with hot water, and, after the introduction of drainage-tubes, closed with deep and superficial sutures of silk. Iodoform was then dusted over the wounds, which were then covered with gutta-percha tissue, with an outside dressing of sublimate gauze. During the last half-hour of the operation the patient was almost *in articulo mortis*, several times becoming pulseless, and twice his respiration stopped. Ether and brandy were injected hypodermatically, the muscles of the chest stimulated by electricity, artificial respiration practised, and as a last resort diluted aqua ammoniæ injected into the median basilic vein. This was followed by a most favorable result, the respiration, although shallow, soon becoming regular, and the pulse reappearing at the wrist. Still for twelve hours the patient was in a very critical condition. The progress toward recovery was very slow, and months elapsed before the wounds of operation were firmly healed. Several of the sinuses remained patent, indicating that some diseased bone had been left behind, and that necrosed bone was still there. This man was kept in the service until March 16, 1890, when he was discharged. Assistant Surgeon Appel, who relieved me at Fort Russell, informs me "that his arm was practically useless from swelling supervening upon any active motion. Discharge from the sinuses would be arrested for a time, but would be renewed after each supervention of inflammation."

Had I not feared that the patient would die upon the table, after my discovery of the extensive necrosis of the shaft of the humerus, I should have amputated at the shoulder-joint, and possibly under the existing circumstances this might have been the preferable operation. At the time of R.'s discharge his general condition was good, yet his arm was useless and constantly liable to inflammation, and he would have been better off without the arm. Of one thing there can be no doubt—that if, at the time of injury, the head and less than two inches of the shaft of the humerus had been excised, this man would have been well in a short time with a fairly useful arm; as it was, sixteen months elapsed before any operation was performed, and as a result his humerus and also the glenoid cavity and coracoid process of the scapula, were necrosed. An examination of the morbid specimen showed that the bullet penetrated the humerus at about its middle and just below the line of junction of the head with the anatomical neck, splitting off a large fragment, but leaving the glenoid fossa uninjured. This man's recuperative powers must have been great, as he stood the drain of a profuse suppuration for sixteen months, and in addition a formidable capital operation. I am indebted to Captain and Assistant Surgeon Frank Ives, U. S. A., and to Dr. Masten, of Cheyenne, Wyoming, for valuable assistance during the operation.

CASE V.—Sergeant H. H., Troop I., Seventh U. S. Cavalry, was admitted to Division Hospital, Pine Ridge Agency, Dakota, December 29, 1890, having been shot in an action with hostile Sioux at Wounded Knee Creek. Sergeant H. was transferred to the post hospital, Fort Riley, Kansas, January 6, 1891. The diagnosis of his case, as given on the "transfer slip," was severe penetrating gunshot-wound of the left arm. Ball entered just external to coracoid process, left scapula, passing through deltoid muscle. "Direction of ball not determined, but supposed to be in neighborhood of joint." If a more precise diagnosis had been made on the entrance of the patient into the Division

Hospital it is probable that the true nature of the injury would have been recognized and a primary operation performed for the removal of the head of humerus. This case came under my charge on January 22, 1891, I having been temporarily ordered to duty at Fort Riley. On January 21st an incision had been made in the shoulder by Assistant Surgeon J. T. Clarke, U. S. A., over the superior portion of the upper third of the humerus, for the purpose of improving the drainage. On account of the swollen and inflamed condition of the parts, I found it impossible at my first examination, to make a positive diagnosis, but felt fully satisfied that the head of the humerus had been struck by the missile and that caries and necrosis of this bone was rapidly going on. The general condition of the patient was bad. He had a daily elevation of temperature several degrees above the normal and he was rapidly becoming exhausted from the profuse suppuration. In addition, he had a severe bronchial catarrh, probably due to exposure en route from Pine Ridge. Although the outlook was not promising, Assistant Surgeon Clarke and myself concluded that it would be advisable to cut down upon the shoulder-joint, determine the extent of injury, and if it should be found necessary, to exsect the head of the humerus. On January 23d, after ether-anesthesia had been induced, two ounces of brandy having been previously administered, I proceeded to carry out the plan mentioned. I first enlarged and deepened the incision previously mentioned, carrying it down to the bone. This incision extended from the center of the superior edge of the glenoid fossa to a point on the shaft of the humerus four inches below. To facilitate the operation, I made a second incision directly over the superior edge of the glenoid cavity and at a right angle to the upper end of the first incision. The first incision opened a pocket containing a large amount of purulent débris. The tissues generally were in bad condition and infiltrated with pus, the small arteries breaking down under the forceps. Following the first incision there was very free hemorrhage, which, on account of the friability of the arteries, was exceedingly difficult to control, it being almost impossible to take them up with the hemostatic forceps. The second incision opened up the joint and it was then ascertained that the bullet had furrowed its way through the superior surface of the head of the humerus and that there was free communication with the medullary cavity of the shaft, the result of osteo-myelitis. It was then deemed best to exsect the head and a small portion of the shaft of the humerus. This was done by passing a chain-saw under the bone, cutting through it, and afterward disarticulating the head of the humerus. It was then discovered that the osteo-myelitis had attacked the humerus below the point of section and that the medulla was converted into purulent pulp. But for the exceedingly precarious condition of the patient I should have amputated at the shoulder, as I was firmly convinced, in case he survived the present operation, that a future amputation would be inevitable. From the beginning the patient did not take the ether kindly, and when I finished the operation proper, even after repeated hypodermatic injections of brandy, he was almost moribund. The operation-wounds were douched with hot sublimate solution 1 : 2000 and rapidly closed with interrupted sutures of silk, a drainage-tube having been introduced. The wounds were then dusted with iodoform and covered with compresses of sublimate gauze. Hot-water bottles were placed around the patient and a half grain of morphine was given hypodermatically. In about twenty minutes there was some reaction and, being able to swallow, he was given some strong coffee and brandy. Stimulants by mouth and rectum were given from time to time, but the patient gradually sank and died of exhaustion at 8 P.M. on the same day, six hours and a half after the conclusion of the operation.

Death in this case probably resulted from the shock of operation and hemorrhage, which latter, although not excessive, was sufficient in the patient's enfeebled condition, added to the shock, to superinduce an unfavorable termination. The quantity of ether consumed was twelve ounces. The length of exsected bone was two inches and a half. The morbid specimen has been sent to the Army Medical Museum. I am deeply indebted to Assistant Surgeon J. T. Clarke for his skilful assistance during the various stages of the operation.

These cases have not been reported because they present any very marked peculiarities or anything original in the way of operation or treatment, but because they are cases representative of injuries which at present are rarely seen in military and hardly ever in civil practice. They are also illustrative of the havoc that the modern rifle-bullet produces when traversing a joint or passing through bony tissue. When one of these projectiles enters a joint, it comminutes everything within three or four inches. The tremendous force with which these missiles are propelled not only makes them destroy and devitalize bony tissues directly in their path, but also makes every fragment another projectile which in its turn breaks and rends. When it is considered that the rifle-bullet, weighing from four to five hundred grains, impelled by the explosive force of from seventy to ninety grains of gunpowder, will kill at a greater distance than two thousand yards—more than a mile—these injuries are not so marvellous. The experience of our Civil War, as recorded in the *Surgical History of the Rebellion*, most strongly trends in the direction of primary operations when large joints are opened and especially so in injuries of the shoulder-joint. During the last twenty years a strong tide of conservative surgery has swept over the world and now no injury is looked upon as necessitating a capital operation unless vitality in the wounded part is absolutely destroyed. This, I think, is a grave error, especially as regards gunshot wounds produced by missiles

the caliber of which exceeds 38. In addition to the apparent injury, the concealed injury must be taken into consideration, as it often becomes the most important factor in the case. Take for instance the case of Sergeant H. The head of the humerus had been furrowed by a bullet of large caliber, with no apparent fracture, and at first sight the injury does not seem sufficiently severe to demand operative interference; yet when we bear in mind the fact that the cancellous tissue for an inch beyond the track of the missile was probably devitalized by the tremendous impact of the ball and that in this class of cases caries and necrosis must almost be the inevitable result, it may be well to consider the future danger, and by timely operative interference save life and limb. A primary exsection would probably have saved Sergeant H.'s life and given Private R. a useful arm. Asepsis will do much, and I know of no heartier advocate of its merits than myself, yet I am of the opinion that whenever any of the large joints are injured by the modern rifle-bullet of large caliber, conservative surgery must fall to the rear and give place to more heroic methods. Civil surgeons rarely encounter such cases, most of the gunshot wounds that they treat being made by bullets of small caliber, from 22 to 38, and propelled by small charges of powder. Here conservative surgery has a most brilliant opportunity, the injury done by such projectiles being limited in extent, because they do not have sufficient force to do much harm outside of their direct course.

THE CAUSES AND PREVENTION OF DIPHTHERIA IN CITIES.[1]

BY W. H. WASHBURN, M.D.,
ASSISTANT COMMISSIONER OF HEALTH, MILWAUKEE, WIS.

THE air that surrounds our earth like a vast sea, at the bottom of which we dwell, teems with innumerable forms of minute organisms, some animal and some vegetable, which, possessing vitality, are subject to constant changes. As with larger organisms, these changes are greatly influenced, if not absolutely caused, by the environment, while the organisms in their turn reciprocally produce or aid in the production of changes in the materials surrounding them. Many of them, such as the putrefactive germs, are incapable of existence within the living body and can only complete their life-history surrounded by that which is dead. Others again are capable of maintaining an existence in living tissues in a pathological state, being either the cause or the effect of such pathological condition as an accidental concomitant.

Since the discovery some years ago that tuberculosis owes its existence to a specific germ, the bacillus tuberculosis, many students have entered the field of bacteriological research, and extensive experiments have been conducted in order to discover, if possible, the microscopic organism or organisms that might be the *materies morbi* of the several contagious and infectious diseases. In the prosecution of these studies, diphtheria has received its full share of attention. At intervals during the past fifteen years or more, the discovery of the specific germ of the disease has been announced, but thus far in every instance further investigation has shown that the pathogenic germ of the disease, if there be such, has not yet been isolated. The Klebs-Löffler microörganism, discovered in 1883–1884, was for a long time thought to be the ultimate cause of the disease, but its claim as such has since been greatly weakened or destroyed, inasmuch as in a number of cases of diphtheria it was absent, and it has been found on the buccal and faucial surfaces in cases of measles, scarlet fever, and in cases in health. Professor Oertel, who early advocated the microbic origin of the disease (*Ziemssen*, 1868), now admits that that theory is only plausible, not proved. He expresses the belief that bacterial organisms cause the disease, though not directly, by producing ptomaïnes that infect the system and render the disease constitutional. The microbe itself is mostly confined to the surface, while the action of the virus is "widespread and deep." Professor Crookshank (*Lancet*, vol. i., 1888, p. 115) states as the result of his own investigations and those of Winckel, Fränkel, Eiselsberg, Löffler, Baumgarten, and others, that the microörganisms once thought to be the *materies morbi* of the various diseases—erysipelas, scarlatina, diphtheria, puerperal fever, surgical fever, pneumonia, typhoid fever, variola, vaccinia, measles, yellow fever, pyemia, septicemia, broncho-pneumonia, syphilis—are one and the same, namely, the streptococcus pyogenes, variously modified by the individual disease. Drs. Welch and Abbott, of Johns Hopkins University (*Bulletin of Johns Hopkins Hospital*, February and March, 1891), have recently published an article on the etiology of diphtheria, and from their own experiments and operations conclude that the Klebs-Löffler bacillus is absolutely the specific cause of the disease, that the blood and tissues are profoundly affected by the virus of that disease, and that microörganisms may gain entrance into the circulation and escape destruction."

We are thus at this time unable to state with any degree of certainty that this or that microörganism is the specific cause of diphtheria, or even that the disease is of microbic origin at all. Indeed, much evidence has been adduced that tends to prove that the virus of the disease is not a specific germ, and

[1] Read before the Wisconsin State Medical Society, June, 1891.

the opinion is held by at least a few good observers that cases may arise from a combination of unsanitary environments not fully determined. Repugnant as this view may be, in this era of germ-theory of infectious diseases, there are nevertheless many facts not to be ignored that appear to support it. For example, of fifty outbreaks of diphtheria in England (*British Medical Journal*, 1888, p. 167) it was only possible in four to trace the first case to contagion. In the remaining forty-six outbreaks, the first cases were all attributed to unsanitary surroundings; in 15 to cesspools, in 10 to defective drainage, in 11 to the keeping of animals in an unclean condition in close proximity to the house, and in the remaining 10 to decaying and offensive manure-accumulations. Cases of the disease, moreover, regularly appear in greater numbers in the winter months, a period relatively unfavorable to the growth of the lower forms of both animal and vegetable life. Thus, in the last five years, during the winter months there were in Milwaukee 245 deaths from diphtheria, whereas during the summer months of the same year there were but 92 deaths from this disease. Barnes (*British Medical Journal*, 1888, p. 167) gives prominence to the fact that the disease is as prevalent in rural districts as in cities and towns, the element of contagion in cities being counterbalanced by decaying animal and vegetable matter, and dampness of soil in the country. M. W. Taylor (*British Medical Journal*, 1889, p. 938) reports a number of cases of diphtheria that appeared to have been caused by mold-fungi on the walls of sleeping-rooms, and he advances the suggestion that these innocent vegetable fungi—aspergillus, coprinus penicillium—may by special cultivation become pathogenic, and referred to the experiments of Grawitz, Sepinger, Nägeli and Buchner to sustain his position. He thought that the existence of zymotic diseases depended, not on individual germ, but upon the soil in which the germ grew, and drew the inference that common molds, both by spores and byssoid mycelia, might originate diphtheria by growing on noxious media. The disease, once having arisen, spreads by contagion in public places and in private houses. In cities, particularly in the East, the sewers have become infected by the virus of the disease, so that many cases are attributed to defective plumbing, by which means dwellings are impregnated with sewer gas.

During the past year diphtheria has been unusually prevalent in the city of Milwaukee, the vast majority of the cases occurring in the outlying districts and in houses having no inside sewer connection, so that we have no reason to think that one sewage system has become the habitat of the *materies morbi* of the disease. Another fact observed in a large number of cases was that the cellars under the houses were low and damp, and frequently contained vegetable matter in a state of partial decomposition. In a number of instances, chickens or ducks were kept in the cellars, and the emanations from their excreta were added to those from decaying vegetable matter. While such environments may not actually cause the disease, it will certainly not be denied that they contribute to that end. Thus Dr. Sternberg (*Lomb. Prize Essay*, p. 38) says: "It seems extremely probable that the diphtheritic poison-germ is capable of generation, independently of the sick, in damp, foul places such as damp cellars, especially under old houses in which the floors come near the surface of the ground, leaving damp, ill-ventilated spaces."

While reluctantly compelled to admit that in spite of the enormous amount of labor expended in the search for it, we are still ignorant of the *materies morbi* of diphtheria, we are fortunately able to speak with greater positiveness as to the means to be adopted in order to limit its spread. Recognizing that all unsanitary environments are predisposing causes of the infectious diseases, reason dictates that such factors should, as far as possible, be removed. The soil should be drained so that the cellars may be free from dampness; decaying animal and vegetable matter should be removed; the thorough ventilation of enclosed spaces, of the cellars and rooms of dwelling-houses, should be secured; the source of water-supply should be investigated, a supply of impure water being a no less potent factor in the causation of disease than an impure atmosphere. Any locality in which attention is paid to these matters will generally exhibit a mortality below the average for the whole community; if these precautions are neglected the reverse will be the case. Thus, to compare four wards in the city of Milwaukee in which the contrast in this respect is striking. The mortality for the whole city for the year 1890 was 17.02 per 1000 of population; in the 15th and 16th wards, with a population of 16,389, in which the environments are comparatively sanitary and the drainage good, the mortality was 13.54 per 1000, whereas in the 8th and 14th wards, with a population of 28,576 and comparatively unsanitary surroundings and imperfect drainage, the mortality was 20.05 per 1000, that of the 14th ward alone being 21.72 per 1000.

The environment having been rendered as favorable as possible, the other measures to be enforced in limiting the spread of diphtheria may be summed up in the two words: *isolation* and *disinfection*. Under existing circumstances isolation cannot be perfectly accomplished in the large cities; an ideal isolation would require the removal of the patient to

an institution especially provided for his care, and the admission to his presence of none but the physician and nurse. So far as I am aware, there are not many cities in this country in which even an attempt has been made to secure such isolation, but in Great Britain and in Germany, where this has been more or less vigorously enforced, the results in lowering the mortality from diphtheria have been very striking (*Sanitarian*, September, 1890, p. 218). In cases of smallpox it is a comparatively easy matter to secure almost ideal isolation, for, with few exceptions, the people, even the most ignorant, are fully alive to the dangers of that disease and the mode of its propagation by contagion; but it is altogether different in the case of diphtheria, a disease which every year carries off its victims by thousands. It is not uncommon to find the room of a diphtheritic patient filled with sympathizing neighbors and their little children, and in order to secure private funerals in these cases it has been necessary for the health officials to use force in clearing the houses of people who were willing to submit their families to the probability of infection. Until this singular ignorance or indifference is removed it will be impossible to obtain more stringent legislation for the isolation of the infected, or even to rigidly enforce the laws already in existence. In 1887, the city of Boston provided a place for the treatment of contagious diseases; since that time public sentiment has been so educated as to render it possible to treat a constantly increasing proportion of such cases in that institution (the Boston City Hospital). An effort is now being made by the Health Commissioner to establish in Milwaukee a system of isolation-hospitals or cottages for the treatment of infectious diseases, and it is greatly to be desired that his efforts may be crowned by success. It seems to me that when public sentiment shall have been properly educated in this direction, and a large proportion of cases of disease, occurring especially among the poorer and more ignorent classes, is treated in hospitals provided for the purpose, to which visitors are not admitted, a great advance will have been made in preventive medicine. The city of London is not only the greatest, but is also the healthiest city in the world, having the smallest annual mortality, very largely because the system of isolation is thoroughly enforced.

Under the present system of placarding houses in which diphtheria or other contagious diseases exist, the number of cases occurring in an outbreak has been materially lessened, but placarding a house only secures partial isolation. If there are other children in the infected family, they are excluded from the schools, public or private, but they run at large upon the streets, enter neighbors' houses, and not infrequently are accompanied to their own homes by their little playmates. They go to the stores and markets, the father continues at his usual occupation, and the mother will even often leave the sick one to go out washing or scrubbing. The disease occasionally makes its appearance in a family the business of which is carried on at home, for example dressmaking or tailoring, and unless under police supervision the members will often continue their pursuits and infect families remote from and unknown to them.

The length of time during which isolation, as far as is practicable at present, should be maintained is an important question. It has been the custom of the Health Department of Milwaukee to remove placards from houses infected with diphtheria as soon as the attending physician reports the case recovered, and that is frequently within a week from the first notice of the disease. All experience goes to show that isolation for so short a time is entirely insufficient. At a meeting of the Society of Public Hygiene of Paris last year (*Sanitarian*, August, 1890, p. 154) it was decided that a child should not be readmitted to school in less than forty days from the date of the onset of the disease. Roux and Yersin (*British Medical Journal*, vol. ii., 1890, p. 753) remark: "Active diphtheritic virus can remain in the mouth for a long time after the malady is cured. Consequently diphtheritic patients should only be allowed to resume their ordinary course of life when they are no longer bearers of the bacillus." It is not uncommon for successive cases of diphtheria to occur in the same family at intervals of several days or weeks, or for the same child, after recovery, to be seized a second time. When families are so situated as to render it impossible to keep the sick in a separate apartment, it has been thought that the danger of the spread of the disease to other members of the household would be lessened if they used a gargle of a one per cent. solution of creolin four or five times a day (*Medical Record*, January 31, 1891, p. 136).

In case of death from diphtheria the body should be immediately wrapped in a sheet saturated with a 1 : 3000 solution of mercuric chloride and should still remain isolated. Funerals should be strictly private, no one being admitted to the presence of the body except those who have already been exposed, and the clergyman whose duty calls him to such places; the service over, the view of the body should be as brief as possible. Strictly private funerals should be rigidly enforced, there being no doubt whatever but that in cases of contagious disease, public or semi-public funerals materially aid in the spread of the disease. This was found to have been the case in Milwaukee during the past year, and our Commissioner of Health found it

necessary to enforce funeral regulations with a firm hand, a sanitary police officer attending every funeral to see that the law was observed. At first, some difficulty was experienced and in some cases physical force was necessary to disperse crowds that assembled about the remains of the dead. The people, however, have now learned that they can have funerals of only the most private kind, and the officers have no further trouble. Following the adoption of this rule by the Commissioner, the number of cases reported weekly has gradually diminished, so that there can be no doubt but that one source of contagion has been removed. While the rule as to private funerals has been thus rigidly enforced, the people have been assured that the law was not enacted for the purpose of restricting the rights of individuals, but for the conservation of the public health.

Disinfection is not less important than isolation in limiting the spread of diphtheria. The atmosphere of an enclosed space cannot be said to have been disinfected until not only the vitality of pathogenic microörganisms has been destroyed, but also the vitality of their spores. As practised by the Health Department, disinfection is not accomplished at all. Infected houses, to be sure, are fumigated, but that is about all it amounts to. We have abundant proof of this. When a member of a family falls a victim to the disease the children are frequently sent to a neighbor's or out of town. After the recovery or death of the patient and the fumigation of the house the children are brought back and in a large proportion of cases in their turn become subjects of the same disease. With the means at our disposal, however, this is all that is attempted for the public, and until that public is willing to place large resources in the hands of its health authorities and confer upon them greater power, it is *all that can be done in this direction.*

[NOTE.—At the present time the Health Department of Milwaukee has under consideration plans for the construction of a disinfecting patrol, by means of which it is hoped to secure more complete destruction of disease-germs, especially in clothing and bedding.]

In Milwaukee one man is expected to "disinfect" about a thousand houses per year, and as a matter of fact he does fumigate nearly fifteen hundred. The public will pay liberally to protect itself against fire and the predatory acts of the criminal class, but for the disposition of its feces and the prevention of disease it doles out the dollars with a niggard hand.

It is no part of my intention to enter at all minutely into the subject of disinfection. To do so would require a paper beyond the limits of this. It will suffice to call attention to the well-settled conclusions reached by experiments and confirmed by experience. The air in the sick-room should be kept as pure as possible; the use of disinfectants here seems to me entirely inefficient and illogical. No human being could long live in a room the atmosphere of which was impregnated with a disinfecting agent in degree sufficient to produce results; hence the futility of using anything of the kind. In fact, by obscuring foul odors emanating from the sick, positive harm may be done the patient and attendants. The only appropriate disinfectant for the room occupied by a diphtheritic patient is *pure air;* hence the room should be thoroughly and systematically ventilated, a change of air being effected as frequently as possible. By this means we effect disinfection by dilution and oxidation. The discharges of the patient should be disinfected, and especial care should be given to the discharges from the nose and throat, which should be received into cloths that immediately after having been used are to be consigned to the flames. As these discharges are the sources of contagion, great care must be taken that they are destroyed absolutely. The clothing and bedding used about the patient can best be disinfected by thorough boiling for half an hour or more. They may equally well be disinfected by immersion for four or five hours in a 1 : 2000 solution of mercuric chloride. The disinfection of the room which has been occupied by the patient must receive careful attention. The windows and doors should be tightly fastened, so that the room is as nearly as possible hermetically sealed, and, according to the directions of the American Public Health Association, three pounds of sulphur should be burned, in the presence of moisture, for every thousand cubic feet of air-space. The fumes of the sulphurous acid should pervade the atmosphere of the room for at least twelve hours (twenty-four would be better), and then the room should be ventilated. The carpets and the furniture should then be removed and thoroughly aired, while at the same time the wood-work in the room is vigorously scrubbed. Unless great care has been exercised in confining the contagion to the room occupied by the patient during the course of the disease, every room in the house should be treated in the same way. By this plan of disinfection I believe the *materies morbi* of the disease can be destroyed, so that susceptible persons may subsequently occupy the rooms with impunity.

Some years ago, while acting as health officer of a town in the northern part of Wisconsin, these means were thoroughly applied in three outbreaks of contagious diseases, namely, scarlatina, smallpox, and measles, with the result that only one house was infected in each outbreak, although the field was a good one for the spread of any one of these

diseases—that is, there had never before been a case of either of them in the town.

When the disease has prevailed to any extent among the pupils of a given school, that school should be thoroughly disinfected according to the directions already given, and I would suggest that, in cities, all of the school-houses should be submitted to this proceeding every year.

THE PURSE-STRING OPERATION FOR CYSTOCELE.

With a Report of Cases.

BY HENRY D. INGRAHAM, M.D.,

PROFESSOR OF GYNECOLOGY IN THE MEDICAL DEPARTMENT OF NIAGARA UNIVERSITY, AND GYNECOLOGIST TO THE BUFFALO HOSPITAL OF THE SISTERS OF CHARITY.

EVERY practitioner of experience is well aware of the trouble and annoyance that a cystocele occasions, not only to the patient, but to himself; of the many expedients to which it may be necessary to resort to keep the prolapsed parts in their normal position, and the want of success that often attends his most persistent and painstaking efforts. As yet no means of mechanical support has been devised that, in a goodly number of the cases that come to us for treatment, permanently benefits or even temporarily remedies the displacement with comfort to the patient. Neither has operative treatment accomplished all that was fondly hoped of it.

To Dr. Marion Sims is due the credit of bringing to the notice of the profession an operation for the relief of cystocele, with which he claims to have had unusual success. In his *Notes on Uterine Surgery* he reports only one failure in the large number of cases operated on. Later operations, however, were not attended with as good results. In fact, owing to the stretching of the tissues, many of the cases operated upon were no better a short time after the operation than they had been before.

The writer believes that whenever a cystocele can be supported with comfort "by any kind of pessary with the only inconvenience of an occasional removal of it, and the substitution for a week or so of astringent tampons to allow an erosion to heal, an operation is not necessary, even though the pessary must be worn continuously; nor in the case of young women, whose vaginæ have not become overdistended throughout, and where a cure may be expected in a year or two, if the parts be properly supported; also in old women past the menopause, whose tissues have become so relaxed and flabby from age and childbearing, and whose vaginal walls have lost all contractility, so that a cicatrix would be sure to stretch soon after the patient left her bed." In cases like those referred to, an operation is not justifiable, because it is not necessary, or because there is no prospect of a cure; but in cases in which the woman objects to wearing a supporter, in which the tissues possess a fair degree of tone, in which the cystocele is too large to be cured by wearing a supporter, and in which there is rupture of the perineum that demands an operation, then anterior colporrhaphy is indicated and will usually be followed by a good result.

During the first years of my operative experience I performed the Sims operation, or some modification of it—but in all cases the sutures, which were of silver wire, were passed as Sims recommended, *i. e.*, transversely. The parts always healed, and for a time the operation appeared to be successful; but in a few months, in quite a large proportion of the cases, the parts began to stretch, and in a few months more the patient was in a condition similar to that existing before the operation. Another objection to this operation is the difficulty of removing the stitches, if the perineum is repaired at the same time, as it has been in all of my cases. Not satisfied with the results in these cases, about fifteen months ago I performed my first so-called purse-string or tobacco-pouch operation for cystocele, with very satisfactory results.

CASE I.—Mrs. B., thirty-eight years old; born in Germany; married nineteen years; was the mother of eight children, the eldest eighteen years old, the youngest two years old. Her labors were always comparatively easy and rapid. For the preceding ten years she had suffered from both rectocele and cystocele, the condition gradually growing worse. Doubtlessly, the perineum had been ruptured at the birth of the first child, although the patient did not know when the rupture occurred. Whenever she was on her feet for any length of time, a prolapse of the anterior vaginal wall, as large as a medium-sized orange, would take place, and every pessary that was tried failed to keep the parts in place. Hence, it was decided to operate. The operation was performed on March 6, 1890, at the patient's house, with the assistance of two members of the graduating class of Niagara University. For two or three days previously the woman had received the preparatory treatment usual in such cases. She was placed in the lithotomy position, and the legs supported by Kelley's Beinhalter. Before the patient is completely anesthetized there is always retching or straining, so that the parts are usually protruded to their full extent. Beginning at a point about half an inch below the meatus, and passing around the protrusion, near its junction with the parts that were in normal position, I cut through the mucous membrane and made a complete sweep of the cystocele, returning to the point at which the incision began. In this case the cut was less than an inch in front of the cervix. Then, with a tenaculum catching the membrane, with a knife I carefully dissected off the entire mucous membrane included within the line of incision, care being taken not to cut too deeply, as the bladder is easily entered, and it unnecessarily weakens the parts to remove more tissue than is

absolutely required. The membrane was removed in one piece, and the bleeding was slight. The denuded surface was two and three-quarters inches in its antero-posterior diameter, and about two and a half inches in the transverse. For sutures I used No. 7 braided silk that had been kept for six hours in melted wax one ounce, and carbolic acid and salicylic acid, of each half a drachm. Threading a piece, fifteen inches long, at each end with the needles that are used in operations upon the cervix, the first suture was passed nearest the cervix, on one side of the raw surface, in and out of the mucous membrane, about a third of an inch from the denuded edge, until the median line just below the meatus was reached. The same method was pursued on the other side with the other end of the suture. The wound was then cleansed, and with the point of a sound pressed in toward the bladder. The edges of the wound were brought closely together by crossing and pulling on the ends of the silk, in the same way as a purse or tobacco-pouch is closed. The suture was then tied. There was a little dimple in the center, but no raw surface was to be seen or felt. One end of the suture was cut short, and the other end brought out upon the thigh, and secured by adhesive plaster. A thick mass is formed on the anterior vaginal wall, the apposed raw surfaces of which adhere to one another without inconvenience, resulting in a firm support to the bladder.

The perineum was repaired by Emmet's operation. The patient was put to bed, and treated in the manner usual after such operations.

For the first twenty-four hours she had nothing but a swallow of hot water every hour or so. After that she was given beef-tea or broth, until on the third day her bowels were moved. This was insured by the administration of a grain of calomel every hour until three doses had been taken, followed by a Seidlitz powder two and a half hours later. The bowels were subsequently moved every second day.. A light diet was given. The catheter was used but twice, the patient being allowed to urinate as soon as she was able to do so. After each urination the parts were cleansed with carbolized water from a fountain syringe. No vaginal douche was used. Ten days after the operation the suture was removed without difficulty, and union was found perfect. The sutures were removed from the perineum at the same time. The patient was kept in bed three weeks, when she was allowed to sit up, and a week later to walk about the house.

This patient is obliged to work hard, and to be on her feet a good deal. At this writing, nearly fifteen months after the operation, the support is apparently as good as it was when she got out of bed. She has no cystocele, and suffers no inconvenience whatever from the effects of the previous injury.

CASE II.—Mrs. H., forty years old, the mother of seven children, the oldest twenty-one years old, the youngest six years, was admitted into the Sisters of Charity Hospital, October 7, 1890. Her labors were said to have been severe, but not tedious. The patient was stout and fleshy, and only complained of the enormous cystocele and the accompanying symptoms. She stated that the trouble had existed for eight or ten years, and that it was growing worse.

The protrusion externally of the anterior vaginal wall was as large as a fetal head. The patient was unable to urinate without returning the prolapse with her fingers. The uterus also dragged down. The perineal rupture was slight. The patient was put in as good condition as possible, and four days later anterior colporrhaphy was performed as in the preceding case, the denudation, however, being much more extensive, involving an area three inches in the antero-posterior diameter, and nearly as large in the transverse. Excepting that the flap-splitting operation was performed on the perineum, the procedure and the after-treatment were the same as in the first case. The stitches were removed on the eleventh day, but the patient was not allowed to get out of bed for three and a half weeks. A week later she was permitted to walk. The union was complete.

The patient, who is a laundress, has followed her occupation for several months past, is well, and now, after the lapse of seven months, presents no indication of her former trouble.

CASE III.—Mrs. W., forty-two years of age, a widow, the mother of three children, the oldest twenty years old, the youngest nine, was admitted into the Sisters' Hospital November 1, 1890. Her labors had been severe and tedious. She had been a domestic for the preceding six years, but was then unable to work.

She had a decided cystocele, with a moderate perineal rupture. A week after admission I operated as in the cases related, doing the flap-splitting operation on the perineum. As the prolapse was not as great in this as in the previous cases, as much surface was not denuded, but the rest of the operation and the after-treatment were the same, except that the catheter was used but once. The stitches were removed on the eleventh day. The patient was allowed to sit up at the end of three weeks, and to walk about at the end of four.

There is now no prolapse or sagging of the parts.

I am aware that the last two cases are too recent to be considered definitely cured; yet, one of the patients has had nearly five months of hard work since the operation, and there are no indications of a return of her former trouble—and this was the worst case of the kind I ever saw. If the operation were not successful it would seem that there should be some indications of a recurrence of the previous condition.

In the last case, as already mentioned, there is now no prolapse or sagging of the parts, yet the woman complains of a dragging sensation in the pelvis, which I attribute to a dislike of work rather than to any pelvic trouble. It will, however, take

at least another six months to tell whether this operation will have been successful or not.

In the first case, the operation was performed sufficiently long ago, and the woman has done enough hard work since to fully demonstrate that in her case the benefit is permanent.

In addition to the foregoing cases, I have performed the operation in two others, with apparent success, yet time enough has not elapsed to determine definitely what the results will be. I am convinced, however, that better results will be obtained from this operation than from any other, as it gives a thicker and firmer support that is less likely to stretch.

One important point in this operation is to denude as large a surface as practicable—the cicatrix is the firmer, and the result is the more likely to be permanent. Another important element in securing a good result is to keep the patient in the recumbent position for some time, until union becomes secure and firm, so that stretching is not likely to occur.

ORIGINAL LECTURE.

THE HEART: ITS MURMURS, THEIR DIAGNOSIS AND TREATMENT, AND THE ACTION OF THE CARDIANTS AS A CLASS.[1]

BY WILLIAM HENRY PORTER, M.D.,
PROFESSOR OF CLINICAL MEDICINE AND PATHOLOGY IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

LECTURE V.

HAVING in previous lectures discussed the physiological actions of alcohol and of digitalis, we to-day begin with a consideration of convallaria.

In regard to *convallaria* there is comparatively little to be said. Of its two active principles only one, convallamarin, is supposed to have any action upon the heart. It, like digitalis, is a CHO compound and is transformed into and eliminated from the system as carbon dioxide and water. While passing through its cycle of change within the body it evolves heat and energy, as a result of which the force and length of the systole are increased. This salutary effect upon the heart appears to be largely due to the lowering of a previously existing unduly high tension; if any increased blood-pressure follows the use of convallamarin, it is a secondary result of the improved action of the heart. It is stated that convallaria should be clinically used when high tension contra-indicates the use of digitalis. It is also said that convallaria in some inexplicable manner stimulates the right heart in preference to the left, and especially in pneumonia. If convallaria primarily lowers arterial tension and secondarily improves the heart's action—which is in accord with clinical observation—its good effects upon the right heart in pneumonia are quite in harmony with general physiological laws and do not necessitate the supposition of an undemonstrable and specific action of the drug. By lowering the general blood-pressure, it very decidedly removes the resistance to the onflowing blood in front of the left heart, thus enabling the left ventricle more rapidly and effectually to pump the blood out of the engorged pulmonary vessels. This, in turn, makes more room within the pulmonary circuit, reducing the resistance in front of the right ventricle, and explains the apparent directly stimulating action upon the right heart, with its clinical results. As convallaria lowers the general blood-pressure, it tends to raise that of the splenic arcade and renal system. It is for this reason not diuretic, except in a mild and secondary manner, through a universal improvement in the general circulation and heart's action.

Strophanthus is another drug of exceedingly uncertain composition. As the evidence stands at present, strophanthus contains two CHO or glucosidal bodies. One of these is freely soluble both in alcohol and in water, the other is insoluble in both. Strophanthus is also said to contain two alkaloids, one of which is toxic and freely soluble both in alcohol and in water. The chemical atomicity of these alkaloids has not yet been formulated, so that their exact action is uncertain. This complex composition and positively poisonous nature of some of the contained active principles render the administration of strophanthus unsatisfactory. Again, the source and purity of the original plant render doubtful the absolute composition of any preparation used. Nevertheless, the most positive results are attributed to the action of strophanthus upon the system.

Personally I have had little experience with strophanthus and that little has been most unsatisfactory. My first acquaintance with strophanthus and its action upon the human economy was at the necropsy table. The subject in question had been admitted to the hospital a few days previously and the diagnosis of a mitral lesion was made. A mixture of strophanthus was administered. The cardiac murmur disappeared and the patient died. The post-mortem examination showed every organ in the body to be macroscopically sound. Microscopically no lesion of sufficient magnitude could be found to explain the sudden death. In every instance in which I have administered or recommended strophanthus, the patient has died, not necessarily from the action of the drug, but from the results of the legitimate pathological conditions. Cognizant of the great uncertainty as to the composition and actions of strophanthus, I have ceased to use it and am patiently waiting for further developments. Being in part a CHO compound, it must over-stimulate and ultimately injure or poison the cardiac muscle, like digitalis and other drugs of similar constitution. If it does not directly increase the blood-pressure, there ought to be no danger of the so-called cumulative or poisonous effects upon the muscle-fibers of the heart. If it does not increase the general tension, its diuretic action must be slight, limited and secondary to the uniform improvement in the circulation by the augmented heart power.

I have had no experience with *Adonis vernalis* or its active principle *adonidin*. If it be true that it is ten times as poisonous to the cardiac muscle as digitalis, I prefer not to experiment with it.

The same may be said of the active principle of

[1] A series of lectures delivered at the New York Post-Graduate Medical School and Hospital.

broom, *sparteine*, which is a toxic liquid alkaloid. It must of necessity be a dangerous drug. It may be a ready and positive cardiac stimulant, capable of being converted into urea, carbon dioxide and water (see table); but in passing through the changes necessary to its elimination as excrementitious matter it is likely to give rise to the development of toxic leucomaïnes or nitrogenous principles, with disastrous consequences.

This brings us to a consideration of the most valuable class of remedies in the treatment of cardiac affections, functional or organic, namely, the true cardiac tonics, or compounds that have a nitrogenous basis and are capable of forming body-tissue or of retarding retrograde metabolism.

POSSIBLE PRODUCTS OF OXIDATION OF THE CHO, CHN, AND CHNO DRUGS.

	Sparteine, *liquid alkaloid*,	$C_{15}H_{26}N_2 + 40O$	=	$CH_4N_2O + 14CO_2$	$+ 11H_2O$.
Ammonium Carbonate,	Salt,	$2(N_3H_{11}C_2O_8)$	=	$3CH_4N_2O +$ CO_2	$+ 5H_2O$.
Coffee,	Caffeine, *alkaloid*,	$C_8H_{10}N_4O_2H_2O + 13O$	=	$2CH_4N_2O + 6CO_2$	$+ 2H_2O$.
Nux vomica,	Strychnine, "	$C_{21}H_{22}N_2O_2 + 47O$	=	$CH_4N_2O + 20CO_2$	$+ 9H_2O$.
Opium,	Morphine, "	$2C_{17}H_{19}NO_3 + 82O$	=	$CH_4N_2O + 33CO_2$	$+ 18H_2O$.
Belladonna,	Atropine, "	$2C_{17}H_{23}NO_3 + 85O$	=	$CH_4N_2O + 33CO_2$	$+ 21H_2O$.

First upon the list, as regards both rapidity of action and efficiency, stands *ammonium carbonate*. By a reference to our table of the possible results of the oxidation of various glucosides and alkaloids it will be seen that theoretically two molecules of ammonium carbonate, by a simple rearrangement of the atoms, without the addition of oxygen, yields three parts of urea, one of carbon dioxide and five of water. As there is no well-established evidence that ammonium carbonate is eliminated in the urine, perspiration or breath in a proportion approximating that in which it is administered, it seems rational to suppose that it passes through a series of changes within the system and makes its final exit from the body in the form of the excrementitious products enumerated. While undergoing this transition within the animal economy, it evolves energy that increases both the force and length of the systole. At the same time, it tends to regulate the cardiac rhythm and arterial tone, not producing decidedly high tension or abnormally rapid circulation. If, with this improved circulatory condition, together with the fact that the nutritive interchange is not arrested, a liberal allowance of proteids is digested and assimilated, and fats, sugars and starch abstained from, a permanent compensatory hypertrophy can rapidly be developed, fully neutralizing any functional and organic defect of a mechanical nature that may have been present.

Owing, however, to the irritating properties of ammonium and its salts, the remedy must not be pushed beyond a certain limit; neither should it be continued for too long a time. Ammonium is particularly adapted for immediate and temporary use, and when a powerful result is wanted at once. Like all nitrogenous compounds, if taken in too large quantities, it may be imperfectly transformed, with the production of poisonous compounds and disastrous consequences.

Five grains of ammonium carbonate, administered every two or three hours, will often place a weak and feebly acting heart in an excellent position to appropriate nutriment to its muscle-fibers more rapidly than any other drug at our command, unless it be alcohol. For quick and temporary action ammonia excels even alcohol in effectiveness, but for more continued action alcohol holds first place among the rapid and powerful stimulants. The most satisfactory results are often obtained by alternating the two.

The next best drug in the list of tonics is *coffee* or its alkaloid *caffeine*. This is also one of the CHNO compounds that is capable of being transformed within the system and eliminated as urea, carbon dioxide and water. While this change is taking place, the quantity of oxygen used is comparatively small. Clinical evidence strongly favors the theory that caffeine aids in the formation of the bodily tissues and gland-structures. If it does not absolutely produce new tissue, it has consummate power to intensify tissue, glandular and mental activity, and at the same time retard retrograde proteid-metabolism. It slowly, but steadily increases the force and frequency of the systole, moderately raises general arterial tension, but positively lowers the blood-pressure in the splenic arcade and renal arteries. It thus acts as a most perfect diuretic. As caffeine does not occasion intensely high arterial tension, but provides a steady and uniform vascular tone, it tends to improve the nutritive interchange between the blood in the arterial capillaries and the perivascular tissues. About three grains of caffeine, three or four times a day, are usually all that is required, and often smaller doses will answer every purpose.

What has been said of caffeine applies in most respects with equal force to *opium* and its alkaloid *morphine*. The latter, however, stimulates the heart the more powerfully, according to the quantity taken; it also has the peculiar property of raising the arterial tension when low and of depressing it when unusually high, in the same manner as alcohol. Were it not for the disturbing effects of opium upon the digestive functions and the action of the liver, no better cardiac stimulant and tonic could be found. So far as the heart and vascular tone are concerned, the action of opium is all that could be desired.

That morphine is oxidized and split up within the

system and escapes in some other form, possibly as urea, carbon dioxide and water, is supported by an abundance of clinical evidence. As, for instance, in those addicted to the habitual use of large doses of morphine, in whom there is no question as to the system being fully under the influences of opium and its alkaloid, careful examination of the urine fails to detect the presence of even the smallest quantity of morphine.

That morphine serves the purpose of a proteid food seems clearly established by the fact that confirmed opium-eaters, for years at a time, subsist almost exclusively upon the drug. In one instance of which I know, the patient lived to be over a hundred years old. This clinical phenomenon of individuals living almost exclusively upon opium was for a long time difficult of comprehension; but when it was recognized that theoretically morphine can be transformed into urea, carbon dioxide and water, that when taken in large quantities it cannot be found in the urine, or at least not in proportion to the amount ingested, nor in the other excretions, together with the clinical evidence that life may for years be almost exclusively (though but poorly) supported by opium, it was understood how morphine helps to build up the tissues and glandular structures, or helps to replace the worn-out protoplasmic elements of the body. If we do not admit this property, we are compelled to assume that in the absence of nutritive elements morphine has an enormous power to stay retrograde metamorphosis and sustain the vital forces in a most extraordinary manner. That morphine, even at its best, is a poor food-stuff must be admitted, and it should be employed only as a medicinal agent in cases of emergency; even then great care should be exercised in its use.

Strychnine and *atropine*, like caffeine and morphine, are of CHNO composition. They also are capable of being converted by oxidization into urea, carbon dioxide and water. While they are thus being converted within the system, they improve nutrition, and stimulate the force and nutritive vitality of the heart-muscle. They favorably modify the vascular tension and develop the highest type of nutritive interchange between the blood within the arterial capillary area and the adjacent perivascular tissues throughout the body.

A uniform cardiac rhythm and a normal vascular tone being absolutely essential for the most perfect nutritive interchange, a similar or slightly augmented action of the heart and a uniformly sustained circulation of a large volume of blood in the arterial capillaries is absolutely indispensable for the development and maintenance of a compensatory hypertrophy, to offset the mechanical defect or to remove the functional irregularity of the heart.

This last class of drugs, called tonics, is found to be the most serviceable for the accomplishment of this desirable result.

Ammonium carbonate for immediate action, followed by the judicious use of alcohol and a well-selected proteid diet, will quickly regulate the cardiac rhythm, steady the vascular tone and augment the nutritive function, not only of the heart-muscle, but of all the tissues and glands of the body.

For a more permanent action and for the development of a lasting compensatory hypertrophy of the muscular fibers of the heart-walls the following formula has been largely used at my clinic and in private practice, and has thus far yielded most satisfactory results:

℞.—Tr. belladonnæ . . . f℥ij–iij.
Tr. opii deod. . . . f℥ij–iv.
Tr. nucis vomicæ . . . f℥iv–vi.
Tr. gentian. co. . q. s. ad f℥iij.
Sig.: f℥j every four hours.

With this combination and line of treatment, a permanently sustained and fully compensatory hypertrophy has been repeatedly established in the patients who have during the past five or six years come to my clinic for treatment. We have frequently pushed the digitalis and continued its use as long as the safety of the patient would admit, but in every instance the heart-muscle deteriorated under its continued administration. With the cardiac tonics, and especially this formula, the desired result could be obtained, even after the damaging effects of digitalis had been produced.

CLINICAL MEMORANDUM.

COMPLETE OUTWARD DISLOCATION OF THE RADIUS AND ULNA AT THE ELBOW.

BY C. R. PONTIUS, M.D.,
OF FREMONT, OHIO.

READING the report of the case published by Dr. Isham, of Cincinnati, in THE MEDICAL NEWS of July 11th, induces me to report my own case of complete lateral external luxation of the elbow-joint. This makes the twelfth, I believe, put on record in America.

The accident is certainly very rare, because Gross says: "The only instance of complete lateral dislocation of the elbow with which I am acquainted is one recorded by Nélaton."

August 18, 1889, F. S., a boy about fourteen years of age, while attempting to perform some feats on a horizontal bar suspended eight or ten feet from the ground, lost his balance, fell, and was picked up with a badly injured right elbow-joint. I examined the joint within one hour after the accident, and found the following conditions existing:

The olecranon of the ulna resting against the external surface of the external condyle of the humerus; the head of radius carried externally, but resting on the coronoid process of the ulna, the arm being slightly flexed, and pronated but little. The joint was necessarily considerably widened, with a corresponding diminution of the antero-posterior diameter. The ligaments of the joint seemed to be, and necessarily were, torn very badly. The joint was badly swollen, and the patient was suffering intensely. A bystander supported the humerus, and I grasped the bones of the forearm near the elbow-joint, using my hand as a fulcrum; holding the wrist with my other hand, I carried the ulna into its proper anatomical position, after which I returned the head of the radius to its normal position, and applied heavy sole-leather splints, properly padded, leaving the arm in a semi-flexed position, and ordered the almost constant application of cold water to the arm.

This was a severe injury, and I had but slight hope of

anything better than an ankylosed joint. In a few days the swelling lessened, and I instituted passive motion as early as I possibly could with safety, thus hoping to avoid the results that I feared. Convalescence was normal. He now has fair use of the arm, with a very good degree of flexion and extension, though neither function is perfect. Rotation is normal. He drives a dray, and has no difficulty in following his vocation.

NEW INSTRUMENTS.

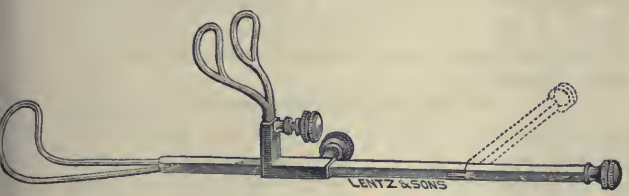
A SELF-RETAINING PALATE RETRACTOR.

BY T. H. WEAGLY, M.D.,
OF MARION, PA.

FOR the thorough examination of the post-nasal cavity, and for the various operations therein, such as the removal of adenoid tissue, galvano-cauterizations, and snaring of hypertrophied turbinates, the need of an effective, self-retaining palate retractor has long been recognized both by surgeon and specialist.

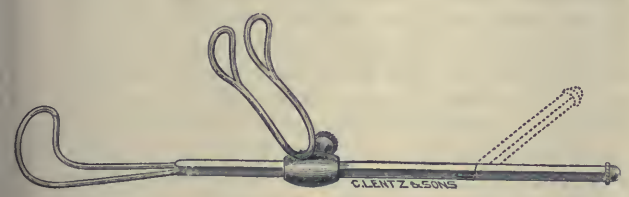
To meet this want the White Retractor, shown in Fig. 2, was brought out. It consists of a bar terminating in a wire loop of sufficient strength to hold the

FIG. 1.



Weagly's Retractor.

FIG. 2.



White's Retractor.

palate. On the bar slides an attachment intended to clamp the upper lip and thus be retained. My experience with the instrument thus formed has convinced me that for several reasons it fails to fulfil its purpose. In persons with a receding lip, or those wearing an artificial denture, it is almost impossible to secure it at all, and in many other cases, at the critical moment of making an application or operating, it is liable to drop from its position, causing great annoyance; and in cases in which it is retained, it often requires such firm adaptation that the undue traction upon the post-nasal parts gives rise to considerable irritation.

In order to secure absolute self-retention, adaptation to varying length of lips, and avoid undesirable traction upon the post-nasal parts, I have modified the lip-clamp, as shown in Fig. 1, by lengthening the clamps and curving them backward. The fenestra are made narrow, and intended to hook within the tip of the nostrils instead of resting against the lip. A pocket with set-screw on the sliding nut permits the adjustment of the shaft of the clamp to the different forms and lengths of lip.

The instrument is, in reality, suspended from the tip of the floor of the nostrils; no undue traction upon the post-nasal parts is required, while absolute self-retention for all purposes is secured.

CURRENT LITERATURE.

THE ACCIDENTS AND SEQUELÆ OF THORACENTESIS.

POTAIN describes the accidents that may be observed after thoracentesis. They may be due (1) *To the pulmonary congestion* that follows the removal of the fluid, and is accompanied by an abundant, albuminous, bronchial expectoration. This bronchial hypersecretion is a result of the entrance of air into the bronchial tubes, which are unaccustomed to this abnormal irritation, and is not dependent upon distention of the lung. In the case of pleuro-bronchial fistula, when the air enters readily, the lung does not undergo distention; nevertheless, albuminous expectoration is at times observed after thoracentesis. (2) *To syncope.* When, for any reason, syncope is feared, special precautions should be taken to slowly remove only a small portion of the fluid. The patient should be operated on in the horizontal position. After the operation he should be kept in absolute repose. (3) *To embolism*, caused by clots from the pulmonary veins. The heart may be arrested, or the emboli may be carried into the large arteries of the brain, giving rise to hemiplegia; into the small cerebral arteries, occasioning abscess; or into other arteries, forming infarcts. Embolism of the pulmonary artery has been observed. When the action of the heart has been hampered by a large effusion, the pressure exerted upon the auricles, the torsion or the compression of the pulmonary veins, conjoined with a certain degree of irritation of the endocardium, may determine coagulation of blood within the heart. After thoracentesis, as soon as the blood-current is normally reëstablished, fragments of the clot may be detached and propelled into the pulmonary artery. Finally, patients, especially advanced in years, may succumb to *cardiac weakness.* When the circulation becomes easier the heart is unable to propel the increased volume of blood, and it ceases to act.

The accidents consecutive to thoracentesis are not rare, although their frequency is not great. An important factor is the quantity of fluid removed. The operation should not be too contracted. It suffices to withdraw one-half of the fluid, which should be allowed to escape slowly, simply by its own pressure. The forced expiration, consequent upon the cough induced by the escape of the liquid, increases the rapidity of the flow. It is the habit of some operators, when the liquid does not readily flow, to encourage the patient to cough. Such a procedure is not unattended with danger.

The frequent transformation of serous into purulent fluid must be related to the apparatus employed in the operation. This accident may be prevented by perfect asepsis. When the period for these accidents has passed, the ultimate prognosis will vary with the age of the effusion and the degree of compression to which the

lung has been subjected. In the case of recent and moderate effusions the pulmonary expansion is readily restored; this often happens in the course of the operation. Under other circumstances no change can be detected by percussion or auscultation in the course of the operation. It may be that the level of the fluid has not been altered, or the lung may not have expanded at once because of a condition of atelectasis. In such a case, while at first there may be no modification, on the next day it will be noticed that the dulness has disappeared. In other cases the lung expands rapidly, the pulmonary resonance and the vesicular murmur return, but on the following day the percussion dulness and the absence of the vesicular murmur reappear. The fluid has not been reproduced with prodigious rapidity. There is simply congestion of the lung, which has come about progressively and slowly, without the usual accompaniment of bronchial hypersecretion.

Should the bronchial hypersecretion be profuse and threatening, the sovereign remedy is morphine, subcutaneously. This arrests both cough and expectoration. For the intense congestion, dry cups and scarifications; very exceptionally, wet cups will be of service.

The changes that take place in the level of the fluid vary and are not always evident. The rapid expansion of the lung may displace the fluid that remains and cause it to appear at a higher level. On the other hand, in case of rapid decongestion of the lung, the level of the fluid may fall rapidly to the lowest portion of the pleural cavity. Sometimes the level of the effusion falls progressively. This is the most fortunate course. In other cases the level of the fluid remains nearly stationary for an indefinite period. Indeed, when the effusion has existed for a long time, the pleura becomes accustomed to the condition; therefore, an effusion should not be permitted to remain in the pleural sac longer than three weeks.

Finally, the fluid may reaccumulate. This is most apt to take place when efforts have been made to remove all of the fluid. In such cases dry cupping and scarifications, blistering and diuretics should be employed; but digitalis should not be administered. In subacute cases purgatives and diuretics (nitre and acetate of potash) should be given. A treatment worthy of consideration is that with sodium chloride. The patient should be placed on a dry diet, and the chloride of sodium administered every two hours in teaspoonful doses. By this means, a considerable increase in the quantity of urine is obtained, with a return of the appetite and the bodily forces, and a rapid absorption of the fluid.—*La Médecine Moderne*, No. 11, 1891.

TREATMENT OF EPILEPSY BY THE COMBINED EMPLOYMENT OF THE BROMIDES AND AN ORGANIC AGENT CAPABLE OF PRODUCING AN ANEMIC CONDITION OF THE NERVOUS CENTERS.

POULET calls attention to the many cases of epilepsy that are rebellious to the isolated action of the bromides. Notably in small children, the bromides administered alone are generally inefficacious. A large number of epileptic adults are no less refractory to the action of the bromides. In other cases these inorganic salts are poorly borne in the large doses in which it becomes necessary to administer them. Under these diverse circumstances good results may be obtained by associating certain organic agents with the bromides. It is to the cerebral ischemia produced by the bromides that their efficiency is due in the neuroses with congestion of the nervous centers, such as epilepsy and eclampsia. The organic agents that are useful in epilepsy act in the same manner upon the capillary circulation. Foremost among these is Calabar bean or its active principle, the sulphate of eserine. Then come picrotoxin and belladonna or the sulphate of atropine. Finally, digitalis meets certain particular indications.

According to the researches of M. Martin-Damourette, eserine determines two antagonistic effects: convulsions, by over-excitation of the motor centers, and paralysis, by a diminution of the excitability of the motor nerves. Large doses kill by over-excitation of the bulbo-spinal apparatus, with resulting convulsive asphyxia, before the function of the motor nerves becomes depressed in a degree sufficient to cause an antagonism to this over-activity of the centers. Small, fractional doses of eserine, on the contrary, suffice to paralyze the motor nerves without producing over-excitation of the nervous centers; once in this state of neuro-paralysis, the animal tolerates even toxic doses of eserine. If fractional or paralyzing doses of eserine are thus antidotal to massive, toxic, convulsive doses, they will also be antidotal to epileptic convulsions.

Atropine exercises upon the muscles effects similar to those of eserine. This is the reason for its efficacy in certain cases of epilepsy. It must be borne in mind that it is necessary to avoid giving belladonna or daturine to patients who are taking eserine. In truth, if eserine and atropine are given in doses non-toxic, but large enough to develop convulsive action, their spasmodic effects unite, and death follows from convulsive asphyxia. If these two agents are given in doses much less than the toxic dose of each, the hypokinetic effects are added to each other, and death follows by paralytic asphyxia. Finally, if the dose of atropine be too small, it will only develop neuro-paralysis sufficient to overcome the convulsibility that would be produced by fatal doses of eserine. One then realizes the antidotism of Fraser.

Side by side with Calabar bean and belladonna, in their anti-epileptic influence, may be placed picrotoxin. This latter, which is neither an alkaloid nor a glucoside, but a neutral principle, also exerts a different action according to the doses administered. In his *Traité de Toxicologie*, Orfila has well described the accidents occasioned by large doses. They are veritable epileptiform crises, with ocular congestion, lividity of the tongue, foaming at the mouth, general insensibility, and convulsions. According to Cayrade, picrotoxin in large doses determines insensibility and tetanic convulsions analogous to those of strychnine. The spasm, however, does not involve the extensors, but the body retains the attitude which it assumed at the onset of the toxic action—in other words, strychnine is tetanic in action and picrotoxin cataleptic. According to Pereira, picrotoxin in moderate doses has a depressing effect upon the voluntary muscles, occasioning obstinate difficulty of movement.

In small children, in whom the bromides alone are often but slightly efficacious in arresting epileptic con-

vulsions, one may associate with them indifferently, picrotoxin, atropine, or eserine. The combination acts surely, with brilliant results. Poulet has, with gratifying success, employed these organic agents in combination with the bromides in a large number of cases of epilepsy in both children and adults. He reports the case of a man, fifty years old, in which bromide of potassium in combination with picrotoxin and bromide of arsenic failed, while complete success followed the substitution of Calabar bean for picrotoxin. In a young woman twenty-one years old, the bromides alone and associated with picrotoxin failed to check the convulsions. Success followed, however, on associating with the bromide of potassium a preparation of Calabar bean or its active principle. In a woman fifty-three years old, after failure with the use of the bromides in various combinations, as well as with Calabar bean and with picrotoxin, the paroxysms were arrested by the administration of the sulphate of atropine associated with the bromide of potassium. A case of cardiac epilepsy was relieved by the combined action of bromide of potassium and digitalis. Poulet believes that the tendency to crime seen in certain epileptics as the fatal consequence of their malady, may be efficaciously combated by the medication suggested. It is necessary to determine which of the organic agents should, in a given case, be preferred. The state of the pupil will, at times, guide in the choice. If, as frequently happens, the pupils do not furnish any positive indication, the selection of the remedy must be governed by the effects produced.

The doses of the drugs will vary according to the age of the patient, individual idiosyncrasy, and the intensity of the disease. In adults, generally from 75 to 90 grains of bromide of potassium for a woman, and from 105 to 120 grains for a man, may be given daily. With this may be given ⅙ of a grain of sulphate of eserine, or ⅙ of a grain of picrotoxin, or $\frac{1}{65}$ of a grain of sulphate of atropine. Thirty drops of the tincture of Calabar bean or 12 grains of the crude drug in powder may be substituted for the eserine, and 30 drops of the tincture of belladonna or 7½ grains of the powdered root for the atropine. If the patient is a cardiac epileptic, and digitalis is preferred, 20 to 30 drops of the tincture, or 3 or 4 grains of the powdered digitalis may be given. The drugs should be given before or during meals.—*Bulletin Général de Thérapeutique*, No. 10, 1891.

POISONING FROM THE EXTERNAL USE OF TOBACCO.

TOBACCO has not been long employed therapeutically save as a domestic remedy. AUCHÉ (*Jour. de Méd. de Bordeaux*, No. 34, 1891) describes various forms in which tobacco has been topically applied, and the toxic symptoms that frequently follow such applications. Tobacco may be employed in the leaf, green or dry, in powder, in decoction, in maceration, in the forms of juice from the stems of pipes, or in vapor. All of these modes of employment have in some cases occasioned toxic phenomena. Two such cases of the enployment of tobacco leaves have been cited by Gallavardin. In the first, in a woman, fifty years old, the external application of the leaves was followed by nausea, vomiting, hiccough, paroxysms of suffocation, excessive prostration, coldness of the extremities, cold, clammy sweats, and a soft, intermittent pulse. In the second case, in a man, thirty-seven years old, toxic symptoms appeared after the application of dried tobacco leaves mixed with honey. In some instances tobacco has been kept in contact with the surface of the body, not for therapeutic purposes, but in contraband pursuits. Thus, in the observation of Nameas (*Gazette des Hôpitaux*, 1864), a smuggler, who had covered his skin with tobacco leaves to escape the impost, presented extreme weakness of the pulse, cold sweats, depression, etc. Hildenbrand relates that the hussars of a troop who, with fraudulent intent, had enveloped themselves in tobacco leaves, though addicted to smoking, presented vertigo, pains in the head, vomiting, etc.

In other cases, poisoning is produced by the employment of tobacco in powder upon wounds, or following the application of an ointment composed of butter and tobacco, as in the cases reported by Kerkring. Wright has reported (*London Med. Gaz.; Annales de Hygiène pub. et de Méd. lég.*, 1874) the case of a man with hemorrhoids, in whom toxic symptoms appeared after sitting for only a few minutes upon a commode containing some tobacco and burning charcoal. More commonly, the poisoning is occasioned by the employment of the decoction, of the infusion, or of the juice of tobacco. Thus, in the case of Landerer, tobacco juice was applied to a chronic skin-eruption on the neck; in that of Westrumb, frictions of the juice of a pipe were applied to denuded portions of the skin; in that of Waterhall, the morbid symptoms manifested themselves after the application of the juice to a scurfy ulcer.

Mercier (*Bulletin de la Faculté*, 1819) has reported the case of a man with the mange, who, with a decoction of a half-ounce of tobacco, rubbed his limbs and trunk morning and evening, and who, on the second day, presented serious symptoms of poisoning. In the case of Murray, three children with scald-head were seized with vomiting, vertigo, sweating and convulsions after having had their heads bathed with a decoction of tobacco. In the case of Marrigues toxic symptoms appeared after the arms, hands, thighs and calves had been enveloped in linens saturated with a strong hot decoction of tobacco. Stanislaus Martin has related the case of a woodcutter and his wife, both with the mange, who energetically rubbed the entire body with a decoction of tobacco, and were soon seized with troublesome symptoms of tobacco-poisoning. M. Milier (*Bulletin de l'Académie de Médecine*, 1845) has reported that lotions of tobacco, employed formerly in the treatment of mange, at times gave rise to vertigo, pain in the head, colic, etc. M. Rougon (*Société de Médecine publique et de Hygiène professionelle*, 1883) observed analogous symptoms in certain colonies of America where the infusion of tobacco was freely used to destroy the chigoe. The presence of these parasites sometimes gave rise to more or less extensive ulcers of the feet. As an insecticide, infusions of a moderate quantity of tobacco leaves were employed. In some instances M. Rougon observed that the applications of this infusion were followed by diarrhea, vomiting, cold sweats, collapse, etc. Auché himself reports a case of tobacco-poisoning in a man, fifty years old, literally covered with pediculi pubis. Not wishing or daring to seek advice upon the method of freeing himself of

these parasites, he decided to use frictions over his entire body with a decoction of tobacco. Soon there appeared heaviness of the head, nausea, vertigo, dimness of vision, cold sweats, excessive pallor of the skin, trembling, great weakness, etc. From this series of observations, Auché draws the conclusion that the employment of tobacco as an external medicament is not free from danger; that tobacco applied to the skin, denuded or not, is capable of producing phenomena of intoxication similar to those produced by the drug taken in toxic doses internally.

THE EMPLOYMENT OF HYDROCHLORATE OF MORPHINE IN MENTAL AND NERVOUS DISEASES.

VOISIN (*Bulletin Général de Thérapeutique*, No. 14, 1891) claims that morphine is of great service in the treatment of certain neuro-mental affections. It is a sedative in the neuralgias, for pain, and for the centers of perception; by this last action it diminishes the sensibility of the brain to painful impressions. It acts efficaciously upon inertia, insomnia, sensory hyperesthesia, upon peripheral neuralgias, upon illusions and hallucinations, and consequently upon deirium. It is useful in mental affections with depression, or when there exists an anxious state, with moanings and lamentations. Many physicians treat slightingly the complaints of hypochondriacs, without considering that in every hypochondriasis there is an element of pain, an initial cause of complaint, and that the patients have, little by little, come to exaggerate the pains that they at first suffered. The ills of hypochondriasis are not only imaginary—there is an element of actual suffering.

In the treatment of the insane, morphine possesses the great advantage that it may be employed by subcutaneous injection. The adoption of the hypodermatic method of treatment of these patients is due to Erlenmeyer, Béhier and Bourdon, and its employment in mental disorders was first practised by Erlenmeyer, Roller and Krafft-Ebing. Voisin first used the drug in 1867; in the last twenty-four years his confidence in this method of treatment has daily increased. The subjective improvement is most encouraging; the patients state that their pains cease shortly after receiving the injections, that with the renewal of force they feel a renewal of will and energy; they are able to return to their occupations; this beneficial effect persists for several hours. Two injections in twenty-four hours are ordinarily necessary. Voisin always commences treatment with small doses (from gr. $\frac{1}{6^{0}}$ to $\frac{1}{3^{0}}$, increasing the dose gr. $\frac{1}{6^{0}}$ daily). The dose is slowly increased until physiological phenomena of favorable prognosis are observed. The patients who are cured, or the condition of whom is ameliorated by subcutaneous injections of morphine, present at first certain symptoms that subsequently moderate or entirely disappear. Among these are redness of the face and conjunctiva, nausea, vomiting, a sensation of heat, a feeling of humility, excessive fatigue, somnolence, emaciation and loss of weight, lowering of the arterial tension, as revealed by the finger and the sphygmograph; then a brightening of the countenance, with a return of intelligence, a clearing of the complexion, a liveliness of expression, an increase in weight, and in women a restoration of menstruation. The circulation presents evident modifications a little after the injection. The cheeks become quite red, and at times remain so for several hours. The conjunctivæ are strongly injected. The pulse changes notably, becoming full and accelerated.

The indications for the treatment of mental alienation with the hydrochlorate of morphine are especially marked in cases in which the return to health is simple and free from congestive complications. The remedy is useful in cases with hallucinations, in conditions of depression, in cases of anxious melancholia in all the forms of alcoholism, in melancholia either with moaning or with stupor, ecstasy, or suicidal tendency. In hysterical insanity decided success has attended this method of medication. Non-congestive puerperal insanity is also most happily treated in this way. In such cases, with hallucinations and maniacal delirium four to five days after delivery, Voisin has employed doses of a grain or more daily. The agitation and hallucinations have ceased at the end of six weeks, and sleep has gradually returned. In one case the patient was cured at the end of two and a half months, and has remained so since. In all the cases in which this method of treatment is adopted, a previous examination of the urine should be made to ascertain the absence or presence of any renal affection with which the hypodermatic medication of morphine would be incompatible.

The duration of the influence of the morphine upon the insane varies according to the degree and the variety of the mental disorder. In tranquil patients, such as certain melancholiacs, or some monomaniacs, the influence lasts nearly twenty-four hours; in maniacal patients with hallucinations and in agitated melancholiacs the duration of the influence, as a rule, does not exceed eight hours, and never reaches twenty hours. This is is also true of agitated hysterical patients. If it is desired to cure or ameliorate the condition, it is necessary to reinforce the morning injection with another in the afternoon, and sometimes with a third later in the day. The last two doses should be larger than the morning dose.

There are certain contra-indications to this method of treatment: (1) Insane patients in whom the lesions are inflammatory, either primarily or secondarily to lesions of the nervous centers, with epileptic insanity, or with any form of general paralysis, are made worse by opium medication; an error of diagnosis may be fatal to the patient. (2) Morphine is of no utility in insanity associated with arterial atheroma, and it may be harmful on account of the congestion to which it gives rise—as a result of which hemorrhages from vascular rupture may take place. The diagnosis of the anatomical nature of the insanity is of the greatest importance. The treatment of congestive or inflammatory insanity in this way is carefully to be guarded against.

Peculiar idiosyncrasies are sometimes encountered in the administration of morphine; some insane patients will receive considerable doses of the drug without manifesting any physiological effect, while others will not tolerate the smallest test dose.

Robert Koch has been made director of the Institute for Infectious Diseases and honorary professor in the medical faculty of the Friedrich-Wilhelm University of Berlin.

THE MEDICAL NEWS.
A WEEKLY JOURNAL
OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, SEPTEMBER 5, 1891.

THE SEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THERE seems to be a general unanimity of opinion that the London meeting of the Seventh International Congress of Hygiene has been an unqualified success. There was a pleasant mixture of so-called popular and of scientific topics, and certainly no one could complain of any severe limitation of choice. Only those possessing the gift of ubiquity could have managed to do anything like justice to the variety presented in the different sections of State Hygiene; Preventive Medicine; Infancy, Childhood, and School Life; Chemistry and Physics; Architecture in its Relation to Hygiene; Engineering in its relation to Hygiene; State Hygiene; and, finally, of Demography. The professors who had, so to speak, the title *rôle* to support, played their parts to perfection. One of them, with substantial as well as etymological accuracy, defined demography as "a method of drawing the public." But the more abstruse departments had also their lighter sides. The science of public health is, no doubt, only another name for an inquiry into the causes of disease, general and specific. But even epidemics, in virtue of their terrors, have a fascination for many minds, while a more wholesome interest will find abundant material in following speculations and suggestions that minister to a better physique; in other words, to the greater capacity of the masses for enjoyment. At first sight there is something gruesome in the catalogue of perils against which it is the object of sanitary science to protect the community. The PRINCE OF WALES, in his inaugural address, spoke the thoughts of many when he observed that "as one looked through the program it was impossible not to feel distress, and even horror, at the multitude of dangers in the midst of which we have to live." But he gave the needed consolation when he added that the great majority of these risks may, with due care, be averted.

The proceedings were naturally concerned much less with what has been already done than with what remains to be achieved. Knowledge in the abstract was not the goal of effort, but knowledge that could practically help mankind. There would be little use in compiling statistics about diphtheria, if the comparison of data thus obtained did not help us to discover the cause of the scourge. In such cases the study of causes is the first step toward that best form of cure—prevention. As yet, the most eminent experts must be content to go on patiently and indefatigably in the road of inquiry, sustained by the hope that, in the end, the mystery will yield to the genius of statistical research. It would have been welcome news had DR. SEATON announced that he and his fellow-laborers in this field had solved the problem; but he did the next best thing when he induced the Congress to pass a resolution calling on the European governments to set on foot a comprehensive inquiry. If the project of international conferences needed justification, it would be found in the necessity for world-wide coöperation in tracking to their origin the more subtle shapes of infectious maladies. India, that in so many other departments of human energy has served to enlighten the West, has been represented at the Congress, and we have no doubt that the attention paid to the Anglo-Indian observers will encourage many a young member of the medical department to make the most of the rare opportunities that his service in that cradle of epidemics gives him. The great Continental specialists who graced the Congress with their presence, and, in many instances, enriched the records of the proceedings with their remarks, may be trusted to do all that the laboratory and the hospitals will permit. But the battle with disease is essentially a soldier's battle. The discussion in the section of bacteriology as to the possibility of the transmission of tuberculosis to the human subject

by the medium of meat or milk as articles of diet, was not, it must be owned, appetizing. But, taking it altogether, it was reassuring, since it showed, on the one hand, that the risk is far slighter than the professional panic-monger would have us believe; and, on the other, it suggested certain practical precautions. It is in the investigation of such subjects as this that the necessity of tempering the results of physiological research and experiment with due regard for the facts and the conditions of every-day life becomes apparent. PROFESSOR BURDON-SANDERSON, for instance, while recognizing that there is a certain degree of danger in the supply of tuberculous meat, added that, if to-morrow a law were passed forbidding its sale, it could not be put into force, because of the difficulty of obtaining inspectors with sufficient skill and discernment. The reflection has a moral that may be carried far beyond the sphere of State medicine. As PROFESSOR BANG, of Copenhagen, recommended, the proper thing to do is to discourage the consumption of under-cooked meat. When doctors differ, a very simple sanitary code is very often the best concordat.

Topics, we need hardly say, vastly more intelligible than those to which we have referred, and no whit less important, engaged the attention of several of the sections. The chemists, it is gratifying to hear, hold that the smoke nuisance is amenable to treatment, and urge the authorities to address themselves practically to its abatement. It will, possibly, be a surprise to some, and a matter of regret to others, that the section of State Hygiene passed resolutions declaring that cremation is a rational and hygienic procedure that is especially called for where death occurs from contagious diseases, and urging the various governments to remove all legislative obstacles to the practice. To legalize is, of course, not necessarily to approve; but the considerations adduced by SIR HENRY THOMPSON undoubtedly went far to show that any other means of disposing of the dead, save burning, may frequently be the means of propagating disease. It may be hinted, however, that the decisions of the Congress of Hygienists, like those of the congress of trades unionists, do not always express the mature and impartial view of the whole memberhood.

On the vexed question whether under any circumstances and in any quantity, alcohol is bad for people of ordinary constitutions, there was by no means unanimity. Moderation approaching abstinence was, indeed, generally commended; but, while DR. ISAMBARD OWEN took up his parable boldly in favor of teetotalism as consistent with perfect health, others were found to plead that a little good wine or beer, or even spirits, taken regularly at meal-times, and always in modest quantities, tends to physical well-being as well as to comfort. Probably, in this conflict of authorities, the outer world will go on doing what it most likes. There is a sort of uncomplimentary concession to the weakness of the flesh in the theory put forward that, as most of us come of ancestors that drank, we should be well advised not to revert rashly to a more innocent regimen.

Everything in these days leads up to socialistic politics, and no one ought to be disappointed if, on such subjects as dinners to under-fed children at elementary schools, the application of scientific principles failed to secure unanimity of belief. There was more thoroughness than wisdom in the suggestion that poor parents should be sternly prohibited by statute from allowing their sons and daughters to sleep in the same room with themselves, and that, if poverty prevented them from providing ample and decent accommodation, the State should step in with the necessary allowance.

More cognate, perhaps, to the legitimate functions of the Congress were the striking reflections offered at an earlier sitting by MR. GALTON as to the law of population. There is certainly novelty in the suggestion that population does not necessarily and indefinitely tend to increase in civilized societies. The question lies at the root of nearly all political and socialistic speculations of the time, and it is to be hoped that when next the experts in demography assemble they will be in a position to elucidate what is still obscure in this important branch of statistical information.

SOCIETY PROCEEDINGS.

SEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

Held at London, August 10 to 17, 1891.

THE Congress was opened by the PRINCE OF WALES, who delivered the Inaugural Address.

DR. BROUARDEL responded on behalf of the French delegates, DR. VON COLER on behalf of the Prussian, DR. CONRADI on behalf of the Italian, DR. ROTH on behalf of the German, and DR. KOROSI on behalf of the Austro-Hungarian.

In the Section of Preventive Medicine, SIR JOSEPH FAYRER delivered the President's Address. He devoted

himself to a consideration of the present aspects of preventive medicine, its recent development, how much it has operated and is now operating for the public good, how slowly but surely it is dispelling the cloud of ignorance and prejudice that has overshadowed and impeded the progress of sanitation, and how it is gradually imbuing the public mind with the conviction that prevention is better and often easier than cure, that health may be preserved, disease avoided, and life prolonged by the study and observance of certain well-known laws, which, correlating the individual with his surroundings, determine his well-being when conformed to, deteriorate or prevent it when neglected, and should enforce the maxim, *Venienti occurrite morbo*.

It is now pretty generally understood that about one-fourth of all the mortality in England is caused by preventable disease, that the death-rate of large communities may be reduced much below that at which it has been wont to stand, that the average duration of life may be made to approximate more nearly to the allotted four-score, and that the conditions of living may be greatly ameliorated. The chief obstacles to improvement have been ignorance and want of belief; a better knowledge of the laws of life and health, more rational comprehension of the nature and causes of disease, are gradually but surely entailing improvement in the conditions of living and in the value of life, and the diminution and mitigation, if not extinction, of morbid conditions which have in past times proved so injurious or destructive to life.

Great improvements have gradually been made in the mode of living. The houses are better constructed, the drainage and ventilation are more complete, the land is better cultivated, and the subsoil better drained; marsh fever and dysentery, at one period so rife, are unknown, and leprosy has long since disappeared. The death-rate is considerably reduced, and the expectancy of life enhanced. Water is purer, food is more varied and nutritious, clothing is better adapted to the climate, the noxious character of many occupations has been mitigated, and the mental, moral, and physical aspects of the people altogether improved; education is general, a better form of government prevails, and the social conditions are far in advance of what they have been; but still the state of our cities shows that improvement is demanded, and one object of this Congress is to point out why and how this may be effected, not only in this country, but throughout the world.

Preventable disease still kills yearly about 125,000, and considering the large number of cases for every death, it has been calculated that 78¼ millions of days of labor are lost annually, which means $38,750,000 per annum; this does not include the days lost by the exhaustion so often induced by the still too numerous unhealthy houses of the poor.

Towns, villages, and houses are still built in an insanitary way; the death-rate is still higher, and the expectancy of life lower than it should be, and though we have got rid of the terrible plagues of the Middle Ages, yet in this century, now closing, other epidemics have made their appearance: cholera has four times visited us; fevers, eruptive diseases, and diphtheria have prevailed; influenza has appeared several times, even recently, and after leaving us last year only to return with renewed virulence, caused in the United States a mortality almost equal to that of the plague.

That we can exterminate zymotic disease altogether is not to be expected, but there cannot be a doubt that we may diminish its incidence, and though we may never be able to reach the *fons et origo mali*, yet we can make the soil upon which the seed is sown so inhospitable as to render it sterile.

The scope and objects of preventive medicine are not limited to the removing of conditions which give rise to zymotic disease, nor even of those which compromise otherwise the physical welfare of mankind, but should extend as well to a consideration of the best means of controlling or obviating those which, attending the strain and struggle for existence, involve over-competition in various occupations, whether political, professional, or mercantile, by which wealth or fame is acquired or even a bare livelihood is obtained, and under the pressure of which so many succumb, if not from complete mental alienation, from breakdown and exhaustion of the nervous system, which give rise to many forms of neurotic disease, and add largely to the numbers of those laid aside and rendered unfitted to take their due share in the natural and inevitable struggle for existence.

The possible deleterious influence of mistaken notions of education, as evinced in the over-pressure which is exercised upon the young, the predominance of examinations, their increasing multiplication and severity, and the encouragement of the idea that they are the best test of knowledge, whilst true mental culture is in danger of being neglected, and physical training, if not ignored, left so much to individual inclination—this is another subject which demands the jealous scrutiny of preventive medicine, the duty of which it is to safeguard the human race from all avoidable causes of either physical or mental disease.

The records of the last fifty years prove the influence exerted by sanitary measures on vital statistics. From 1838 to 1854 the expectancy of life was for males 39.91, for females 41.85 years; from 1871 to 1880 it had increased to 41.35 and 44.66 years respectively.

The improved sanitation saves more children's lives, but the conditions of gaining a living are harder than they were, which accounts for the expectancy of life for adult men being less.

A further proof of the effects of sanitary work is a decreased death-rate.

An important result of the observations of the able medical officers of the Sanitary service of India has been to show that cholera is to be prevented or diminished by sanitary proceedings alone, and that all coercive measures of quarantine or forcible isolation are futile and hurtful.

In preventive, as in curative medicine, knowledge of causation is essential. It is obvious that any rational system of proceeding must have this for its basis. A certain empirical knowledge may be useful as a guide, but no real advance can be expected without the exactitude which results from careful scientific observation and induction. The spirit of experimental research, however, is now dominant, and progress is inevitable.

It is impossible to exaggerate the value of the scientific researches which have led to the antiseptic methods of preventing the morbific action of microörganic life, whether the toxic effects produced by them, or those

induced autogenetically in the individual. Theory has here been closely followed by its practical application in prevention and treatment of disease, whilst the study of bacteriology, which is of such remarkable preëminence at the present time, is opening out sources from which may flow results of incalculable importance in their bearing on life and health.

Important as are the researches into microbiology, there are other factors to reckon with before we can hope to gain a knowledge of the ultimate causation of disease. It is not by any one path, however closely or carefully it may be followed, that we shall arrive at a full comprehension of all that is concerned in its etiology and prevention, for there are many conditions, dynamical and material, around and within us, which have to be considered in their mutual relations and bearings before we can hope to do so; still we may feel satisfied that the causes of disease are now being more thoroughly sought out than they ever have been—all honor to those who are prosecuting the research so vigorously—and that though individual predilection may seem sometimes to dwell too exclusively on specific objects, yet the tendency is to investigate everything that bears upon the subject, and to emphasize all that is implied in the aphorism, *Salus populi suprema lex.*

A discussion was held on the "Mode of Preventing the Spread of Epidemic Disease from One Country to Another."

In the Section of Bacteriology, SIR JOSEPH LISTER delivered the Presidential Address. He paid a graceful tribute to the work of Pasteur and of Koch, and made brief reference to the work of Roux in diphtheria; of Metschnikoff in phagocytosis; of Behring and Kitasato in tetanus; of Hankin, and of Vaillard and Yersin.

DR. A. LAVERAN discussed the Etiology of Malaria. He described the chief forms of the hematozoön found in malaria as:

1. The spherical bodies. 2. The flagella. 3. The cruciform bodies. 4. The rosette-like bodies. The flagella could only be demonstrated in fresh blood; the other forms, however, were well seen in preserved blood. The blood in paludism was easily studied by rapid drying and fixation of the specimen by heat, followed by staining with a concentrated solution of methyl-blue or gentian-violet; a double staining could be effected by successively immersing the specimen of dried blood in concentrated aqueous solutions of eosin and of methyl-blue, whereby the red cells assumed a rosy hue, and the leucocytes, together with the parasitic bodies, were colored blue. Nuclei had been observed in both the spherical and the cruciform bodies. Two, and even three, different varieties of this hematozoön had been described (polymorphism). Similar hematozoa had been found in different animals—frogs, lizards, marsh-tortoises, birds. In many species of birds there was to be found a hematozoön so similar to that of paludism that most observers regarded the two forms as identical. The similarity was very marked, yet several points of difference existed; thus—in the blood of birds the cruciform bodies were not found; the parasitic elements were intra-corpuscular and never became free, as was often the case with the true paludic hematozoön; and the ameboid movements of the spherical bodies were much less notable in the case of the organism found in birds' blood. On the other hand, this latter hematozoön had been observed in birds living in non-marshy regions; it frequently caused no inconvenience to its host, and the inoculation of blood containing this hematozoön had given only negative results.

The subject of "Asiatic Cholera" was taken up.

PROFESSOR HUEPPE gave the result of his observations on the growth of Koch's cholera bacillus in artificial media. He had obtained positive results in his experiments on animals. He also described certain of the chemical changes produced by cholera bacilli in the media in which they grew.

DR. KLEIN did not accept the view that the bacillus described by Koch was the active agent in the production of cholera. He demonstrated the several species of comma bacilli isolated from typical acute cases of cholera by Dr. D. D. Cunningham.

PROFESSOR MAX GRUBER supported Koch's conclusions.

DR. BRUCE said that he had found the injection of a pure cultivation of Koch's bacillus killed guinea-pigs but not rats. He did not agree with Professor Hueppe in thinking that the comma bacilli formed spores. He found that comma bacilli grew well inside of eggs, and would live there longer than anywhere else.

PROFESSOR MILLER read a paper on "The Mouth as a Source of Infection." He enumerated the local and general diseases traced to the action of bacteria in the mouth, described the method of examining saliva for pathogenic bacteria, gave the results of inoculations with the saliva of healthy persons, and discussed prophylactic measures.

MR. HENRY SEWILL read a paper on "The Bacteriology of Dental Caries." He stated that the active agents in caries are acids and microörganisms.

PROFESSOR ALLEN MACFADYEAN presented a communication on "The Behavior of Bacteria in the Small Intestine of Man." He detailed the results of a study of the evacuations through an artificial anus at the termination of the ileum made for the relief of strangulated hernia.

PROFESSOR MAX GRUBER described and demonstrated a new pyogenic microörganism—micromyces Hoffmanni, belonging to the hyphomycetes, which morphologically closely resemble the actinomyces.

PROFESSOR CROOKSHANK read a paper on the "Streptococcus Pyogenes and the Identity of the Streptococcus Pyogenes and the Streptococcus Erysipelatosus."

MR. SAMUEL G. SHATTOCK and MR. CHARLES A. BALLANA read a paper on "Cancer as an Infective Disease." They stated that thus far the cultivation of a microbe of carcinoma had been unsuccessful. The transmission of carcinoma from one species to another had also failed. Numerous reasons were advanced for considering carcinoma as a parasitic disease. It was shown by statistics that carcinoma has become more prevalent.

DR. SHERIDAN DELÉPINE read a paper on "Psorospermosis as a Possible Cause of Epithelial Tumors." He endeavored to show that psorosperms produce tumors similar to papilliferous adenomata. Psorospermoid bodies were found in twenty-two of a large number of epithelial tumors. Definite proofs of the psorospermic nature of the lesions were, however, wanting. Psoro-

sperms from the liver of a rabbit can easily be cultivated in nutrient gelatin or in the clear serum obtained in some of the psorospermial cystic tumors. Dr. Delépine concluded that the bodies found were not true psorosperms.

PROFESSOR SIMON DUPLAY and DR. MAURICE CAZIN reported that they had been unable to find coccidia in carcinomata. They believed the so-called fuchsin bodies to be products of hyaline degeneration, not confined to carcinoma.

PROFESSOR D. J. HAMILTON read a paper on "Bacterial Necrosis of the Liver." The disease has been found in the cow, sheep, donkey, guinea-pig, and badger, and is characterized by rounded or irregularly-shaped deposits in the substance of the liver, deeply or superficially. The masses are hard, as a rule, yellow in color, and resemble neoplasms. Microscopically they are found to be liver-tissue in a state of necrosis, with the outlines of the liver lobules and cells perfectly preserved. The necrosis is evidently not due to interference with the blood-supply. Dense masses of microörganisms, usually bacilli, are found in the portal vein or invading the necrotic mass.

In the Section of the Relations of the Diseases of Animals to those of Man, SIR NIGEL KINGSCOTE delivered the Presidential Address.

DR. E. ROUX read a paper on the "Prevention of Hydrophobia," giving an account of the results obtained at the Pasteur Institute.

DR. GEORGE FLEMING presented a communication on the "Prevention of Rabies in Dogs." He insisted upon the destruction of rabid dogs, the control of ownerless dogs, the utility of muzzling, and the necessity for the taxation and registration of dogs.

DR. J. BARDACH reported the results of the Pasteur method of treatment as carried out during four years at the Bacteriological Institute at Odessa. The results were exceedingly satisfactory and compared favorably with those of other methods of treatment.

DR. HIME stated that those who had studied the Pasteur method were satisfied that it was established upon a scientific basis.

M. NOCARD, of Alfort, mentioned a prophylactic treatment which was applicable to domestic animals, at least to herbivora. M. Galtier had some time ago announced that the injection of rabic virus into the veins of the sheep or the goat did not produce hydrophobia, but rather conferred immunity. He himself had quite recently made a number of experiments, by which he had been able to show—(1) that the intravenous injection of rabic virus would not produce rabies in horses; (2) that if the quantity of virus injected was sufficient, these inoculated equines acquired an immunity against rabies; (3) that it was possible to protect equines inoculated by intra-ocular injection when there were introduced into the veins certain quantities of dilute rabid nervous material. From these experiments he thought it might be hoped that a prophylactic treatment might arise out of the labors of M. Galtier.

DR. C. R. DRYSDALE stated that, having frequently attended the inoculations at the Institut Pasteur, he could speak with the greatest admiration of the immense care and intelligence shown in carrying out the treatment. As to the issues of Pasteur's plan, he considered it now clearly proved that, when only 0.92 per cent. of deaths had occurred after this treatment, as compared with probably more than 20 per cent. in similar cases, it was an indulgence in an improper degree of scepticism any longer to deny the value of the treatment.

DR. OSTERTAG said it had been suggested that the muzzle was ineffectual because cats and wolves carried the disease as well as dogs, but that cases of this sort were rare was proved by the experience of Germany. Since the passage of the laws regulating the contagious diseases of animals, rabies had become a rare disease and only occurred along the French and Russian borders. These laws provided that all mad dogs, and those suspected of rabies, or even of having been bitten, were to be killed, and all dogs and cats within a radius of fifteen miles must be kept in confinement during three months each year. In Berlin all dogs wore muzzles, and a case of hydrophobia had not been reported for ten years. As a result of these laws a Pasteur Institute in Germany was unnecessary.

DR. ELIZABETH BLACKWELL called attention to the suffering of dogs made mad to produce virus; she herself had visited the Pasteur Institute and had seen a series of dogs in the various stages of induced madness.

PROFESSOR PERRONCITO indicated that in the municipality of Turin they had a laboratory for the Pasteur anti-rabic treatment that gave exceedingly good results, as published by the director, and he also mentioned that an experimental inquiry upon the same method of treatment had been commenced in connection with such animals as oxen, horses, etc., with most encouraging results.

(*To be continued.*)

SECOND CONGRESS OF TUBERCULOSIS.

Held in Paris from July 27 to August 2, 1891.

(Continued from p. 252.)

DR. BABES, of Bucharest, presented a communication on "Bacterial Associations in Tuberculosis." He stated that in children he had found that Koch's bacillus was often associated with other varieties of microörganisms. In every case of tuberculosis that he has examined he has found, together with Koch's bacillus, the staphylococcus and the streptococcus. In tuberculous arthritis the microbes of suppuration are always found; in tuberculous ulcerations of mucous membranes the streptococcus is also always present. As to the influence of these microörganisms on the development of Koch's bacillus, Babes is inclined to think that they favor the growth of this particular organism, as is exemplified in the guinea-pig, that suffers from suppuration and becomes more apt to contract tuberculosis; while, on other hand, it is not impossible that the secretions of Koch's bacillus produce a favorable soil or medium of culture for the other organisms. This fact of microbic association being known, therapeutic action ought to be directed to the destruction of the secondary microbes, which are more easily destroyed than Koch's bacillus.

DR. HALLOPEAU, on the other hand, presented a communication on the "Genesis of Tuberculous Suppurations," in which he denied the fact of the intervention of pyogenic microörganisms in all tuberculous suppurations. Cold abscesses, suppurative adenitis, and empyema may be exclusively due to Koch's microbe, the irritation

being inaugurated by the secretions of that particular organism. Hallopeau maintained that even the suppuration of lupus may be exclusively produced by the bacillus tuberculosis. The suppurative effects of the products of Koch's bacillus have even been demonstrated by injections of Koch's fluid, which give rise to suppuration, and it is known that this lymph has been previously sterilized.

DRS. VERNEUIL and BARETTA presented a communication on the "Influence of Microbic Association in the Evolution of Cold Abscesses," in which they endeavored to elucidate the cause of the transformation of a latent cold abscess into an acute one; as a result of their investigations they found that the presence of staphylococci and streptococci was necessary to transform a cold abscess into an acute one. In a cold abscess that manifests acute symptoms, *streptococci are always found*, while the presence of the staphylococcus is exceptional. As to the practical significance of this fact, it is known that if a cold abscess opens spontaneously, without having presented acute inflammatory signs, there remains a fistulous opening that heals with difficulty, the points of the abscess being infiltrated with tubercles; if, however, the abscess opens as the result of an intercurrent acute condition, or after running an acute course has been opened by the surgeon, the question arises, Have the pyogenic microbes any anti-microbic action as regards the bacillus of tuberculosis? MM. Verneuil and Baretta believe in the anti-bacillary action, for they have inoculated animals with inflammatory products obtained from an abscess that was opened after inflammation had taken place, and the result was negative as regards the development of tuberculosis.

M. ARLOING reported having conducted experiments to determine the relative influence of heat as applied to the virus of tuberculosis, and found that when tuberculous virus after being heated was inoculated into animals it occasioned suppuration, while, on the contrary, when the substance had not been heated, tuberculosis manifested itself.

DR. OLLIVIER presented a communication on "Tuberculosis Amongst the Working Classes." He stated that the most important cause of the propagation of tuberculosis is a failure to disinfect the rooms occupied by tuberculous patients.

When a patient amongst the working classes dies, the rooms occupied are given up, and in ninety-nine cases out of a hundred no antiseptic procedures are adopted in connection with the infected rooms. The consequence is, that those who subsequently occupy the same rooms, at the first cold which they may get, develop a chronic bronchitis, the specific character of which soon shows itself—a result of the drying of the tuberculous products expectorated by the former occupants of the room, which float in the air with the dust. As disinfection will never be properly carried out by the very persons concerned, it ought to be applied by sanitary boards in the respective districts, as is the case with cholera, variola, diphtheria, etc.

Several letters were read upon "The Influence of Influenza on Tuberculosis." DR. DUBROUDY, of Hyères, stated that certainly grippe cannot transform itself into tuberculosis if tuberculosis be not present in the system. In regard to the influence of one disease upon the other, several facts are to be considered: the nature and grave character of influenza; the nature and degree of tuberculosis; and, finally, the degree of resistance of the patient. Patients in the third stage of tuberculosis usually die as a result of the disease, while those in the second stage rapidly pass into the third stage and progress to a fatal termination.

PROF. CORNIL, of Paris, presented an interesting communication on "The Suppuration of Tuberculous Lesions." Suppuration is not simply the passage of white blood-corpuscles outside the bloodvessels; between pus and simple inflammatory edema there exists a wide gap, for the pus is made up of dead white blood-corpuscles, while in edema these same corpuscles or leucocytes are living. Pus is certainly the result of the action of certain microbes of great variety and also of certain toxines.

Moreover, pus is accompanied with a more or less extensive destruction of surrounding tissues which must be got rid of, while the leucocytes of simple inflammation play a useful part, since they aid in the reconstruction of the tissues. This explanation was given to show that the inflammatory edema that is consecutive to an injection of Koch's tuberculin, whatever may be the vascular congestion or migration of the corpuscles, does not alone lead to suppuration. In tuberculous lesions of the skin and lungs Dr. Cornil has made many injections of Koch's tuberculin, the doses varying from 0.001 gram to 0.150 and 0.200 gram, without occasioning the development of a single abscess.

Although in several instances M. Hallopeau has found Koch's bacillus alone present—an observation confirmed by Dr. Cornil—still the latter believed that in many cases of glandular and osseous tuberculosis other microbes are present, more especially the staphylococcus, and in rare cases the streptococcus. On the other hand, M. Arloing has observed that suppuration produced by Koch's bacillus was in direct proportiôn to the attenuation of the microbe—a relation that has been demonstrated in the case of other microörganisms Two factors present themselves in this connection—the virus and the medium of culture.

Suppuration may be considered as an evidence of a feeble degree of reaction, due to an attenuation of the microbe, or to the nature of the culture-medium, the reaction produced by some one pathogenic microbe varying not only with the medium on which the organism has been cultivated, but also with the nature of the tissues of the individual. This is exemplified in experiments made by M. Pasteur, who has produced suppuration in guinea-pigs with hens' cholera—suppuration that healed spontaneously. Drs. Cornil and Chantemesse have produced localized abscesses in the guinea-pig and in rabbits with the microbe of the pneumo-enteritis of the hog; while the same pneumococcus that, without causing death, produces an abscess in a guinea-pig, will in from twenty-four to thirty-six hours kill a mouse by acute septicemia.

In regard to suppuration, Prof. Cornil stated that, together with Dr. Babes, he had some years ago produced an encysted abscess in a guinea-pig by means of the bacillus of bird-tuberculosis, to which this animal is refractory. Suppuration is also an evidence of the great resistance of certain tissues to the tubercle-bacillus, as is

exemplified in local tuberculosis, such as tuberculous orchitis, etc. In conclusion Dr. Cornil stated that in regard to suppuration in tuberculous lesions, not only must the degree of virulence of the microbe be considered, but also the nature of the culture-medium, which in this case is constituted by the tissues, or the organism itself.

MM. HALLOPEAU and JEANSELME read a paper on "Researches on the Nature of Erythematous Lupus." The point in question is whether or not lupus is tuberculous. As an illustration he took the case of a man that since youth had had a typical erythematous lupus and also some glandular tuberculosis, and finally died of acute miliary tuberculosis. Inoculations were made to prove the difference between the lesions, and while from the miliary granulations and caseous glands positive results were obtained, from the tissues from the lupus the results were absolutely negative; three guinea-pigs that had been inoculated were found absolutely normal one hundred and ninety days after the inoculation.

From clinical observations it is probable that erythematous lupus is a result of tuberculous infection, and if it is not inoculable in animals it is because the virus has been attenuated; hence the negative result of inoculations cannot be opposed to clinical facts. As Dr. Besnier has stated, the tuberculosis may be so modified in the organism of an animal that it will appear in a non-transmissible form in that culture-medium—the organism.

DR. CAPRET, of Paris, read a paper on "Medicated Air in the Treatment of Pulmonary Phthisis." For the preceding fifteen months he had treated with most favorable results all stages of phthisis with inhalations of compressed air impregnated with creasote. Patients are placed in a compressed-air chamber for four hours; the pressure of the atmosphere is gradually increased by means of a pump the air having been charged with creasote by passing through scraps of wood saturated with creasote, as a result of which the air contains on an average about 0.001 gram of creasote per liter. Within this chamber, in half an hour, one attains a pressure of one and a half atmospheres, which is maintained for three hours; it is then again gradually diminished for another half hour. During such a sitting of four hours the patient has absorbed about four grams of creasote; these séances are repeated daily. Dr. Capret has treated thirty patients, and in all the results obtained were most satisfactory; in six the bacilli disappeared from the sputa.

An interesting communication was presented by DR. L. H. PETIT, in the name of DR. SCHOULL, of Turin, in relation to "The Transmission of Tuberculosis by the Waste of Food Derived from Tuberculous Patients." Two cases were observed that became tuberculous by eating the remains of the food given to a young tuberculous woman. This led Schoull to institute the following experiment: He took three kittens that had been nursed by the same animal; two were fed with the remains of food obtained from tuberculous patients, and both died from a generalized visceral tuberculosis; the third one, that was used as a control-animal, was nourished with the remains of food obtained from non-tuberculous patients, and these presented no trace whatever of tubercular lesions. In a practical point of view, it is a most interesting fact to be known, as in poor families contagion in this way is quite possible.

DR. LESPINE presented a communication on "A Not Yet Well-known Complication of Lupus Vulgaris." The case upon which the report was based was observed in the service of Dr. Leloir. It was one of lupus vulgaris that was suddenly complicated by the appearance of general symptoms of a profound character—a typhoid state, with a rapid rise of the temperature, that in a few days rose to 40° C. (104° F.); at the same time, around the ulceration, phlyctenulæ developed that filled with pus, the ulceration extending as the suppuration increased. Local antiseptic treatment was sufficient to bring about a cessation of almost all the symptoms.

Dr. Leloir emphasized this complication, as it necessitates special therapeutic interference, for while non-ulcerative lupus contains no pyogenic microbes, the ulcerative variety contains many, among others the staphylococci; hence, in such cases, it is easily understood that antiseptic treatment will do more good than anti-tuberculous treatment.

(To be continued.)

CORRESPONDENCE.

LEIPZIG.

The Medical Department of the University—Professor Zweifel—The New Frauen-klinik—Sänger—The Polyklinik.

THIS is one of the most delightful cities, and it seems especially so after a sojourn in Berlin, with its hurrying crowds and almost constant noise. Here are found, comparatively at least, quiet and rest; here one moves in freer space, breathes a purer air, and beholds an ampler sky; there is less hurry, less apparent confusion and fewer confounding noises.

It is needless to say that great historical events belong to this city, and that it contains many localities associated with famous characters or incidents. Here one may see the room in which Napoleon awaited the, to him, disastrous result of the battle between the French troops and the allied armies—the year I will not attempt to give, lest I might go as far astray as the popular novelist, Rudyard Kipling,[1] does in regard to an ophthalmoscopic examination to which his hero is subjected by one of the leading specialists of London. The houses in which Gœthe and Schiller each lived for some years may be seen by the curious, and certainly they will visit the Auerbach cellar, made famous by "Faust," and see the curious paintings of scenes from that work, and examine the memorials of its great author, such as a few books, autographs, locks of hair, etc. An hour may be spent in the market house, one of the largest and most convenient, I think, to be found anywhere, albeit a person comparing the space given up to flowers to that devoted to meat might come to the conclusion that Leipzig people live more on sentiment than they do on animal food.

While my belief is that a physician ought to have a knowledge of something more than medicine, something

[1] The following passage is found in this author's story called The Light that Failed: "The blaze of a gas-microscope in his eyes made him wince."

besides familiarity with diseases and their symptoms, with drugs and their doses, advancing and strengthening his character by a larger culture, including literature, art, philosophy, and history, yet let me come to matters strictly professional. The medical department of Leipzig University has about nine hundred students, and of these probably between two hundred and three hundred will at the same time be engaged in the study of obstetrics and diseases of women; I was at one of Professor Zweifel's clinical lectures, and certainly there were not more than one hundred and thirty students; but the session is just about ending and it is to be supposed that many had gone home. The student, first one, then another, examines the patient, brought in from the ward upon a bed, and, after questioning him, Professor Zweifel corrects his errors if he has made any, and then makes some observations upon diagnosis, treatment, etc. He seems to me one of the best of teachers. In personal appearance he greatly resembles the late Dr. Albert H. Smith—not quite so large nor of so dark a complexion. His position as Professor of Obstetrics and Diseases of Women gives him the control of one hundred beds, and there is no other Professor in this department of the University; he has assistants—some of whom are well known by readers of German contributions to obstetric or gynecological literature, Döderlein for example—assistants only, not petty competitors and attempted rivals or superiors—such efforts by themselves or their friends would soon consign them to private life and personal contempt.

Dr. Zweifel kindly had one of his assistants take me to the new Frauen-klinik now nearly completed, though it will not be ready for occupation for a year. This building, which, independently of the ground, will cost more than three hundred thousand dollars,[1] is a model, so admirably devised and so well constructed. It will have a large lecture hall and operating theater, besides a small room with cement floor and walls of tiles for laparotomies; there is a room or hall for instructing midwives and provision for at least two hundred patients, I should think. Besides all this there is a large parlor, a waiting-room for patients and a consulting-room, and probably eight or ten additional rooms—cooking, dining, sleeping—all for the Professor of Obstetrics and Diseases of Women in the University of Leipzig, whose position carries with it the title and duties of the Director of the Frauen-klinik. He can have as many private patients to consult him at the hospital as choose to come. He will also have some private rooms for those who require operation, etc. When will anyone occupying a similar chair in any of the medical institutions of the United States have similar opportunities, rights, and immunities? But a far more important question—and it is unselfish, while the former might seem so—when will medical colleges, especially trustees of these institutions, recognize the importance of securing for medical students facilities for practical instruction in obstetrics and diseases of women corresponding with those that are found in the most important schools in Europe?

My chief object in coming to Leipzig was to see Dr. Sänger and some of his work; indeed, had it not been for his kind invitation I should not be here at all. Dr. Sänger, who has done more than anyone else to bring the Cæsarean operation into good repute, is a man thirty-eight years old, rather slight in form, very deliberate in action, and I should think more decidedly of a mathematical than of a poetical cast of mind; he formulates rules and obeys them. I have not seen him perform many operations, but the few that I have seen would be ample compensation for a much longer visit. His almost invariable use of silk, of course first made thoroughly aseptic, was quite a contrast with what I had witnessed in Berlin; his rare employment of wet sponges, but of dry antiseptic gauze for application to a bleeding surface, was also a notable difference. Finally, in a hysterectomy, the pedicle was treated extra-peritoneally, being ligated, not with wire but with rubber tubing; and for the ordinary transfixion needles he employed two ordinary sail needles, and the method seemed to me admirable in execution. I saw him perform his operation for ruptured perineum, but this has been described in at least one text-book well known to the American profession, so that I shall not attempt a description, and, at any rate, words without diagrams would be useless or confusing. The number of sutures, of fine silk, for uniting the sides of the vaginal flap astonished me, but the immediate result was perfect, part fitting to part with complete accuracy, and the new perineum promised complete success; Dr. Sänger stated that he had left the internal sutures five weeks without their causing any irritation. Another operation, not original with Sänger, however, nor did he so claim it (it probably was first derived from or suggested by one of Simon's operations), performed by him was stitching the cervix to the vaginal vault. The following is the method: a strong, curved needle, threaded with catgut, or silk, is held by the forceps; then the cervix is drawn so far down that a finger in the rectum can feel the retro-uterine cul-de-sac; next the needle is carried through the cervix on one side of the canal and into the peritoneal cavity, whence it is made to emerge in the vaginal vault; a similar ligature is passed on the other side; then each is tied. The operation is designed for retroflexion or retroversion, but its value is yet to be determined. Dr. Sänger did not speak hopefully of it.

The hysterectomy was a difficult operation, but admirably accomplished; it was performed on account of a myoma that had in part undergone cystic degeneration. The tumor not only occupied considerable space in the abdomen, but had also grown downward by the side of the vagina, which constituted the chief difficulty in the operation.

Dr. Sänger's operations are performed at his private hospital, a most admirably constructed and arranged building—indeed, considering too the ample and pleasant grounds attached to it, the best institution of the kind I have ever seen. I think it quite possible that the building alone cost sixty or seventy thousand dollars.

In addition to his hospital work and other private practice, Dr. Sänger has one or two hours a day at the "Polyklinik," where a number of patients attend, and where he gives instruction to his private students. Among the patients there one day I saw a girl of thirteen, pregnant by her father; the mother, who had left her husband, was pregnant by another man—a revelation of

[1] Leipzig has about one-third the population of Philadelphia, but when will the latter have such a building?

depravity which Dr. Sänger said was very rare, and he asked me not to think (as of couse I would not) such cases as characteristic of German morals.

Dr. Sänger is an earnest advocate of the *dry* treatment of wounds, *e. g.*, after the closure of an abdominal incision he applies iodoform very freely, not for any antiseptic properties, but simply to keep the parts dry; so, too, after a perineal operation, iodoform is applied and over it dry antiseptic gauze, and this dressing is subsequently repeated twice every twenty-four hours. He is a thorough believer in antiseptic surgery and has almost a wealth of means—sterilizing apparatuses, antiseptic solutions, etc., for carrying his faith into practice. He called my attention to the value of sand (sea sand is the best) for mechanical disinfection of the hands, using it with warm water and soft soap, the *sapo viridis* of the United States Pharmacopœia, I believe.

I ever gratefully acknowledge myself a debtor to Dr. Sänger for much useful knowledge.

Let me beg those who take the time to read these letters to pardon the frequent use of the first person singular; those who know the writer need no apology or explanation, but those who do not may be assured that it does not arise from any egotism, but simply from a desire to make the narrative free from all obscurity, and to secure for it some vivacity. It was said that only a good swimmer should attempt to read the writings of Heraclitus. It is my desire that whatever I write may be so plain that it can be readily understood by any reader.

T. P.

NEW YORK.

Public Baths—Dirty Streets—Leprosy Scares—Artificial Ice—Impure Water.

IN my last letter I referred to a proposition to establish public baths of the variety known as the "rain baths," or douche; already such a bath has been put in successful operation. The work was done under the auspices of the New York Association for Improving the Condition of the Poor, and the committee having the matter in charge has shown good judgment in selecting a site convenient to the multitudes that throng our down-town tenements. It is situated in Center Market Place, but a short distance from the indescribably filthy dens of Bayard Street, and "the Bend" in Mulberry Street. The building is divided into a number of bath rooms, so that the bather does not have to sacrifice privacy for cleanliness. In the women's portion of the edifice, provision is made for washing and drying clothes. Contrary to the opinion of the promoters of this scheme, the people of the neighborhood were not long in availing themselves of the privileges of the new bathing-place, as evidenced by the fact that 125 persons patronized it the first morning it was open. This is certainly very encouraging—so much so, that one is inclined to believe that after all the people of Gotham will see their foreign population looking clean and civilized long before they will have an opportunity of enjoying the comfort of clean streets. Our long-suffering people have grown so accustomed to having their Schneiderian membranes and conjunctivæ irritated and inflamed by dust, laden with all kinds of filth, to say nothing of multitudes of germs, that they have ceased to murmur; but now their burden is made heavier, and those who are compelled to remain in the city during the hot months are regaled with the stench arising from garbage barrels which are left unemptied on the sidewalks for several days at a time. If some impulsive citizen revolts at this state of affairs, and appeals to the police, he is told it is "out of their jurisdiction;" and if he complains to the street-cleaning department, he is met by an official, who shrugs his shoulders and sadly informs the indignant and anxious citizen that it is impossible to do more with the present appropriation, and that "Street Commissioner Beattie is a very much abused man." What effect the condition of our streets will have upon the public health remains to be seen, but at the present time it is a topic of deep interest to our sanitarians.

Nearly every summer, the dulness and apathy incident to this season induce some of the newspapers to start up a "cholera scare," or something of the kind. This time it is our old friend, the leprosy, which is honored with this prominence. Some of the press correspondents have nearly gone into hysterics over the alleged discovery of one or two cases of leprosy, and have proceeded at once to denounce what they are pleased to consider the insufficient steps taken by the Board of Health. They seem to forget all about what has been said in regard to it on similar occasions in the past, and are entirely oblivious of the fact that a leper has been in one of our large city hospitals for a number of years.

The contrast between this year and last, as regards that most necessary article, ice, is pleasant indeed—that is to say, to the consumers; but if I am not greatly mistaken, all but a favored few of the dealers are wroth with themselves, and with the world in general. It is certainly very silly and inconsiderate on the part of the consumers to desire cheaper ice, especially when they can at the same time obtain a purer article, but such is the fact, and so strong has the tide set in favor of artificial ice that it has become necessary for the losing parties to circulate broadcast all sorts of rumors concerning the unhealthfulness of the new product. And so it has come to pass that people, ordinarily well informed, may be heard saying that they are afraid to use the artificial ice, because "it contains ammonia," although they would not think for a moment of objecting to eating ice-cream on the ground that salt has been used in the freezing process. Again, many persons have received circulars containing an analysis made by Professor Leeds of a sample of ice alleged to have been made by *one* of these new companies, in which it is shown that the water from which the ice was made contained much noxious organic matter, and that the water from this ice contained quite a notable proportion of zinc. It is on account of the presence of this latter impurity that I refer to the circular. These companies all claim to make the ice from *distilled* water, and, as is well known, such water exerts a far greater solvent action on metal pipes through which it passes than does ordinary water; hence, if galvanized iron or lead pipes are used, zinc or lead is likely to be found in the water. The artificial ice factories have been so busy this season that it is not improbable that some of them have been hastily constructed, and the process of manufacture carelessly conducted, and that in consequence an otherwise highly commendable industry may be productive of much mischief.

Of kindred interest is the condition of our water

supply, and it must be said that the water is at present more than usually bad. Ever since the completion of the new aqueduct, about a year ago, it has frequently been so muddy as seriously to interfere with laundry work, and this has increased to such a degree that recently men have been employed to go from hydrant to hydrant and "blow off" the muddy water that had accumulated. Notwithstanding this muddiness, it is only within the past few weeks that the water has actually tasted badly. The condition of our water supply is at present the subject of an investigation by the chemists of the Board of Health, and so far as their work has been made public it shows that there are many sources of pollution of the Croton water. I do not wish to be understood as indorsing the sensational reports printed by an enterprising journal, which has set on foot an independent investigation of the Croton water-shed. In this connection, it is interesting to recall a paper read by Dr. C. G. Currier before the Section on Public Health of the Academy of Medicine, on the "Self-purification of Flowing Water." The author stated that, in general, water containing many and various bacteria is unsuitable for drinking purposes unless it has undergone the sterilizing influence of heat. Chemical tests to determine the purity of water are entirely inadequate; the modern science of bacteriology can alone be relied upon to settle this question, and it was on this account that the aid of bacteriology had been invoked in determining the amount of purification taking place in flowing water. Following out this line of investigation, it has been found by observations on the sewage flowing from Chicago, that the water showed evidence of purification after flowing eighty miles; and this was still more apparent at Peoria, one hundred and fifty miles distant. This purification is due to dilution, sedimentation, the antagonistic action of bacteria, and particularly to oxidation. Acids present in the water seem to exert no distinct disinfectant action, for in all kinds of bottled carbonated waters living bacteria may be found, unless these waters have been subjected to some sterilizing process. The Central Park reservoir, in this city, shows a certain amount of purification resulting from sedimentation, but much undesirable contamination of the water here might be avoided by moistening the dusty and much-frequented walks and roads in the immediate vicinity of this reservoir. Observations in the old Croton aqueduct showed that the average flow was two and a half miles per hour, and that providing no further contaminations occurred, the water became distinctly purer after flowing a few miles. Some have claimed that a water supply can be readily purified by pumping air freely into the water, but the value of such a measure would seem to be very questionable when it is remembered that numerous bacteria have been found in ice formed from the spray of waterfalls. Here the combined action of agitation, aëration, and freezing, have failed to destroy the bacteria. While Dr. Currier claims that the most practical and the safest way of sterilizing water, in order to render it potable, is to boil it for an hour, Dr. Chandler seems to have been staggered by the hardihood of bacteria which persisted in living in the icy spray, for he was quoted as saying that he did not think it made much difference whether or not one drinks polluted water, and he backs up this rather audacious statement by pointing to certain statistics which show that Albany, which receives the water polluted with the sewage of Troy, reports six cases of typhoid fever, while Troy, during the same period, had five cases of this disease. Such conflicting opinions, I fear, will tend to swell the numbers of those who object to drinking water in any form.

NEWS ITEMS.

The Mississippi Valley Medical Association will hold its seventeenth annual session at St. Louis, October 14th 15th and 16th. A program of interesting papers has been prepared, and provision has been made for a thorough discussion, in which representative men from various sections of the country have been invited to participate. Dr. I. N. Love is the chairman of the Committee of Arrangements.

Proceedings of the Tenth International Medical Congress.—It is announced that the publication of the *Proceedings* of the Tenth International Medical Congress, held at Berlin last year, has so far progressed that the reports of section five for internal medicine will be issued in a short time. This will conclude the second volume (including the sections of anatomy, physiology, general pathology, pathological anatomy, pharmacology, internal medicine and pediatrics). Volume V. (containing the papers of the sections of dentistry, hygiene, railway hygiene, climatology, medical jurisprudence and military sanitation) will be ready for distribution on the completion of sections fourteen and sixteen. The reports of sections to complete Volumes III. and IV. have gone to press.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 18 TO AUGUST 31, 1891.

WYETH, M. C., *Captain and Assistant Surgeon.*—Sick-leave of absence extended three months, on surgeon's certificate of disability.

KIMBALL, JAMES P., *Major and Surgeon.*—Is granted leave of absence for twenty-five days.

POTHEMUS, ADRIAN S., *Captain and Assistant Surgeon.*—Is hereby granted leave of absence for one month, to commence on or about September 3, 1891.

PILCHER, JAMES E., *Captain and Assistant Surgeon.*—Is relieved from duty at Fort Clark, Texas, on expiration of leave of absence, and is assigned to duty at Fort Ringgold, Texas.

HAVARD, VALERY, *Major and Surgeon.*—Granted three months' leave of absence, to take effect on or about September 5, 1891.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE TWO WEEKS ENDING AUGUST 29, 1891.

DU BOSE, W. R., *Passed Assistant Surgeon.*—Ordered to duty at Naval Academy, Annapolis.

HARMON, G. E. H., *Surgeon.*—Detached from Naval Academy, Annapolis, and wait orders.

WELLS, HOWARD, *Surgeon*—Ordered for temporary duty at Naval Station, New London.

A. A. HOEHLING, *Medical Inspector;* J. B. PARKER, *Surgeon;* and O. D. NORTON, *Passed Assistant Surgeon*, ordered to Naval Academy, Annapolis, September 3d, to examine physically candidates for admission to the Naval Academy.

HESLER, F. A., *Passed Assistant Surgeon.*—Detached from U. S. S. "Pensacola," and ordered to the U. S. S. "Charleston."

CORRECTION.—For the name of Dr. Longaker, in the twelfth line from the bottom of the first column of page 238 of THE NEWS of August 29th, read Dr. Langrehr.

ORIGINAL ARTICLES.

ONE THOUSAND CASES OF LABOR, AND THEIR LESSONS.

BY G. W. H. KEMPER, M.D.,

MEMBER OF THE DELAWARE COUNTY (IND.) MEDICAL SOCIETY, EX-PRESIDENT OF THE INDIANA STATE MEDICAL SOCIETY, MUNCIE, IND.

A MEDICAL man, after twenty-five years of practice, ought to be able to contribute something useful to his professional brethren. I therefore offer the following contribution to our obstetric literature with a hope that it will interest and instruct the reader. The experience reaches over a period of a quarter of a century (1865–90)—a time embracing the buoyancy and ardor of early professional life and prolonged into maturer age when theories give way to the permanency of facts.

The records comprise my first one thousand cases of labor at or near full term of gestation, excluding cases of consultation. All the labors occurred in Delaware County, Indiana, in a healthy region of country and among a vigorous class of women, but few of whom were foreign-born. The facts were recorded in my case-book soon after the labors were completed, noting my failures as well as my successes, and every case as it occurred in my practice (except in consultation cases) has been faithfully given in this report. With religious care I have not added to, nor have I taken away "from the things which are written in this book."

My report will be all the more interesting from the fact that it represents a country practice instead of a city or a hospital practice—the usual sources of obstetrical statistics. Possibly it will more nearly represent the general experience of the average obstetrical practitioner.

As I now look over the records of my cases, I see where I might have improved in some difficult cases, and I also note that better surroundings might have given better results. The country practitioner is deprived of many of the advantages of a city practice. Competent assistance is ever ready and abundant in the city and hospital, but it is not so in the country. Often alone have I watched with painful anxiety difficult cases in the lying-in chamber—far removed from friendly counsel—and, only aided by faithful women, have met and performed some of the trying operations of obstetric practice.

My case-book contains a thousand chapters, each one written amidst the ever-varying duties of a physician's life, and if I may be pardoned for comparing a little thing to a great one, I may say of it, as the celebrated Dr. Johnson said of his dictionary, "that it was written, not in the soft obscurities of retirement or under the shelter of academic bowers, but amid inconvenience and distraction."

There were 737 different women involved in the 1000 cases, distributed as follows:

Attended	550	women	1 time	=	550
"	129	"	2 times	=	258
"	43	"	3 "	=	129
"	12	"	4 "	=	48
"	3	"	5 "	=	15
	737				1000

The following table shows the labors ordinally grouped, with the total number in each. I arrange them in two groups of a first and a second five hundred, to show a remarkable similarity:

No. of labor.	1st 500.		2d 500.		Total.
1st	174	+	160	=	334
2d	117	+	116	=	233
3d	74	+	87	=	161
4th	38	+	51	=	89
5th	34	+	29	=	63
6th	17	+	17	=	34
7th	13	+	14	=	27
8th	16	+	14	=	30
9th	5	+	5	=	10
10th	6	+	4	=	10
11th	0	+	1	=	1
12th	0	+	1	=	1
13th	1	+	0	=	1
Not stated	5	+	1	=	6
	500		500		1000

The number of labors for each month is:

Month.	Births.	Month.	Births.
January	84	July	102
February	78	August	107
March	82	September	83
April	66	October	95
May	74	November	75
June	85	December	69
	469		531

The smallest number of births occurred in April, and the largest in August. A majority (62) of the births occurred in the last six months of the year.

The following table indicates the number of births at each particular hour of the day. The time indicated is that nearest to the even hours. For instance, if a birth occurred at or previous to half-past one o'clock, it is marked 1; if one or more minutes later, it is marked 2.

Hour.	Births.	Hour.	Births.	Hour.	Births.
1 A. M.	44	9 A. M.	45	5 P. M.	38
2 "	47	10 "	48	6 "	30
3 "	56	11 "	51	7 "	39
4 "	35	12 M.	27	8 "	32
5 "	53	1 P. M.	37	9 "	42
6 "	56	2 "	51	10 "	43
7 "	46	3 "	28	11 "	27
8 "	50	4 "	38	12 "	48

Not stated, 2

From the above it will be seen that the smallest number of births occurred at 12 M. and 11 P.M., while the largest number was at 3 A.M. and 6 A.M. The popular opinion that more births occur at night has a slight show of support. Counting from 7 P.M. to 6 A.M. inclusive, we have 522 births; while from 7 A.M. to 6 P.M. inclusive, 489 were born—a difference of 33 in favor of the night hours. A greater disparity, however, is shown if we contrast the first half of the day with the second half; as from 1 A.M. to 12 M. inclusive, 558 births occurred, while from 1 P.M. to 12 P.M., only 453 births occurred—a difference of 105 in favor of the first half of the twenty-four hours. There is little doubt that more labors begin during the night than during the day.

In order that the reader may not suspect inaccuracies in my figures, I desire that he will bear in mind that I had 13 cases of twins, and while the labors will number 1000, the births will number 1013. This fact remembered will save confusion in the remaining statistics.

In order to show at a glance a general summary of my cases, I will introduce at this point statistics showing by way of comparison the 1000 cases in two groups of 500 each. The similarity of the two columns is striking as demonstrating how medical statistics repeat themselves and show a tendency to uniformity.

	1st 500.		2d 500.		Total.

PRIMIPARÆ.—Exactly one-third of my cases were primiparæ, the youngest of whom was aged fifteen years, and the oldest forty-two years. The duration of labor in the latter, from the first pain to the birth of the child, was 9 hours and 15 minutes.

In a recent article Dr. Courtade, of France, says: "The influence of age upon the sex of children is still problematical." On the contrary, Kleinwächter, who based his observations on 920 primiparæ, says: "The older the primipara is the more likely is she to bear a boy; those from twenty to twenty-one years of age, however, bear more girls than boys." In my cases I found that 44 primiparæ at the age of twenty-one, gave birth to 31 females. This is the only remarkable fact in my observation of the influence of age on sex. I found that 256 primiparæ, whose ages ranged from fifteen to twenty-four years, bore 118 males (47 per cent.), and 138 females (53 per cent.). I also found that 54 primiparæ, whose ages ranged from twenty-five to forty-two years, bore 20 males (47 per cent.), and 34 females (53 per cent.). In short, I found that at all ages the females generally outnumbered the males. I think there is one rule we may safely affirm, namely, that in the sum total, primiparæ bear more females than males. On this fact hang all the laws touching the problem of the relation of sex to first births. It explains why females predominate in illegitimate births—a large proportion of this class of unfortunate women being primiparous.

MULTIPARÆ.—By reference to the table the number of each particular order of multiple births can be seen. The fact of small families will be discovered when we notice that the births numbered 1st, 2d, and 3d, amount to 728, while all the others, from 4th to 13th, only amount to 266.

SEX.—The number of children born in the 1000 labors was 1013; of these, 518 were males and 495 were females—an excess of 23 of the latter. This is not far from the usual ratio of births, namely, 106 males to every 100 females. My 667 multiparous cases show 372 males and 307 females, an excess of 65 males. The reverse is true of the primiparæ, namely, the 333 show 146 males and 188 females, an excess of 42 females.

VERTEX PRESENTATIONS.—Of the 1013 children born, 971 presented by the vertex, a ratio of 95.85 per cent., and only 3.15 per cent. for all other presentations. Dubois gives 94.7 per cent. for the vertex. Late statistics of Churchill, in 98,409 labors, give 92.8 per cent. for vertex, and 7.2 per cent. for all others. Thirty-six of the children were stillborn. In 2 cases the hand came down by the side of the head, and in 2 the cord was prolapsed.

FACE PRESENTATIONS.—I met with 2 cases of this presentation. Both presented with the chin to the

symphysis. One labor was unaided; in the other, after some delay, I used forceps.

BREECH PRESENTATIONS.—Of this variety I had 26 examples—80 occurring in primiparæ and 18 in multiparæ. 11 males and 15 females were born. 23 of the children were saved and 3 were lost. One of the latter occurred at a tenth and another at a twelfth labor, both being quite tedious; the third occurred with a primipara, death being due to the delayed after-coming head. Dubois reckoned a mortality of 1 in each 11 children presenting by the breech. Two of the cases were twins, and another was one of twins, its companion presenting by the vertex.

FOOTLING PRESENTATIONS.—I met with 11 footling cases, 3 occurring in primiparæ and 8 in multiparæ. 6 males and 5 females were born. 8 children were saved, and 3 were lost. In 6 instances the child was one of twins. One of the fatal cases occurred in a primipara; both feet presented complicated with a prolapse of the cord. In the second fatal case the cord was around one of the thighs. The third was a feeble child, one of twins; its companion having perished about the fourth month, remained and infected the mother. This case will be mentioned further on. In 1 case a knee presented with the opposite foot—a presentation that Madame Lachapelle met with but once in 3445 deliveries.

SHOULDER PRESENTATIONS.—I met with 3 cases of this cross-presentation. In the first case the right shoulder presented with the funis protruding through the vulva. The child was a female. In the second case the left shoulder presented, the hand and forearm protruding through the vulva. The child was a female. In the third case the right shoulder protruded, but the arm did not come down. The child was a male.

February 19, 1873, I was called in consultation by Rev. Dr. B. F. Day, to see Mrs. A., in her fourth or fifth labor. Upon examination I found the right shoulder presenting, head in left iliac region, and the back of the child directed forward. While I was making the examination the arm descended, and the hand protruded through the vulva. Following in rapid succession, the thorax was detected, then the hip, and finally the breech, while the arm remained in the vagina. Labor was soon terminated, and I had the rare opportunity of witnessing a spontaneous evolution—a process, it is said, that Professor Bedford so much desired to witness, and died without the privilege. The child was medium-sized, and stillborn.

TWINS.—Thirteen pairs of twins were born. 1 labor was primiparous, and 12 were multiparous. 11 males and 15 females were born. 23 children were saved, and 3 were lost. In 3 labors both children were males, in 5 both were females, and in 5 one of each sex. In 11 cases two sacs were present, in 1 a single one, and I failed to record it in 1. 14 were vertex, 4 breech, 6 footling, 1 a shoulder and funis, and 1 vertex and hand presentations.

In 4 cases both presented by the vertex, in 1 both by the breech, in 1 a vertex and breech, in 6 one a vertex and the other a footling, and in 1 a shoulder and funis, and the other vertex and a hand. In 8 cases one placenta was present and in 5 two were present. In 11 cases both lived, and in 1 both were dead (cuticle detached), and in another, one died. The interval between the births of the two children was five minutes in 3 cases, ten in 1, fifteen in 4, twenty in 1, thirty in 3, and fifty in 1.

CONVULSIONS.—I encountered 9 cases of convulsions. Of these 7 were I-para, 1 II-para, and 1 V-para. 8 of the women recovered and 1 died. All the children presented by the vertex. 7 were saved and 2 lost. 2 of the children were males and 7 were females. 1 male and 1 female were lost. The woman who died gave birth to a female that lived. 1 woman had one convulsion, 2 had three, 1 had four, 1 had five, 1 had seven, 1 had nine, 1 had eleven, and 1 (fatal case) had numerous. In 7 cases the convulsions began prior, and in 2 subsequent to delivery. Of the 7 cases commencing before delivery, 1 ceased the day before, 2 ceased at, and 4 continued after, delivery. One of the post-partum cases began before the expulsion of the placenta—the patient that had five convulsions; in the other case they did not begin until sixty-five hours after delivery and were numerous. In one case the right shoulder was dislocated by the violence of the convulsions, the reduction being effected the following day while anesthetized. Forceps were used four times to expedite the labor. Venesection was resorted to twice. Bromide of potassium and chloral were used in a number of cases. Chloroform was used in a few cases. Morphine was used hypodermatically in the last 5 cases. I used it in from one-fourth to one-half grain doses, repeated as seemed necessary. I consider this remedy the sheet-anchor in this disease. I have used this treatment with excellent results in many other cases that I have seen in consultation. I also think I have prevented an attack of convulsions in women who, while in labor, were seized with a severe headache and other premonitory symptoms of the disease. It is a most excellent plan to unload the bowels in all these cases, and this is easily and readily done by giving a large dose of calomel mixed in a teaspoonful of melted butter and poured down the patient's throat. This mode of administration I learned from the lamented George T. Elliot. If the reader will try it in the next case he meets, he will thank its author for suggesting it.

POST-PARTUM HEMORRHAGE.—I met with 12 cases

of this accident. 2 occurred in primiparæ and 10 in multiparæ. 5 males and 8 females were born, all alive. One followed the birth of twins. One occurred in connection with adhesion of placenta. One case occurred after the use of forceps. One of the primiparæ was a "bleeder." Immediately after the expulsion of the placenta the uterus rapidly filled with blood. With ergot and manual compression the clots were expelled, only to refill in a few seconds. This process was repeated a number of times. The hemorrhage was controlled after the loss of a large quantity of blood. The lady, a German, informed me that a sister in her native land had flooded to death after a confinement. My patient removed to a Western State and I never learned her subsequent history. For many years I gave a dose of ergot as soon as the placenta was cast off into the vagina, but meeting with no case of hemorrhage for a long time, I abandoned the habit, only to meet with three cases of flooding in close proximity, so that, especially with multiparæ, I again resumed the after-dose of ergot. I am very favorable to manual compression of the uterus for the expulsion of the placenta, and I also maintain the fixed contraction with the hand over the hypogastrium for a few minutes; thus hemorrhage is guarded against and after-pains largely prevented. With this precaution I rarely meet with a case of severe after-pains.

ADHESION OF PLACENTA.—Eleven cases of adhesion occurred, 2 with primiparæ and 9 with multiparæ. 6 males and 5 females were born—2 stillborn—both females. Two of my cases happened with one of the women whom I attended in five successive labors; in the other three labors the placenta came away normally. One of the women had had adhesions in two of her former labors, in one of which I removed the placenta for the attending physician. The firmness of the adhesions in this subject was remarkable. It was one of those cases, as Barnes remarks, "where the structures of the uterus and of the placenta are so intimately connected—seeming, in fact, to be continuous parts of one organization—that you cannot tell where placenta ends and uterus begins." Another of my patients had suffered an adherent placenta in a former labor. If we meet with adhesion of the placenta in one labor we may very properly fear a repetition in subsequent ones. All my patients had a short and favorable convalescence.

PROLAPSE OF FUNIS.—The cord presented in 5 of my cases, 1 in a primipara and 4 in multiparæ. Sex was represented by 1 male and 4 females. Only 1 of the children, a female, was saved. In 2 of the cases the presentation of the child was by the vertex, in 1 a shoulder, in 1 a double footling, and in the remaining 1 the vertex with the arm and hand extended in advance of it. In 1 case pulsation had ceased in the cord when I was called and no effort was made to replace it. In 1, with shoulder presentation, I turned and saved the child. In the remaining 3 cases I made an attempt to keep the cord above the brim by postural treatment, but the effort was not successful.

PLACENTA PREVIA.—Three cases of this terrible complication were met with—1 in a II-para, 1 in a IV-para, and 1 in a V-para. In each case the child presented by the vertex. One of the children was a male and 2 were females. In each case the attachment was lateral. In all I detached the placenta as far as I could reach with the finger, and ruptured the membranes. In one case I used a tampon. When the head engaged the os all hemorrhage ceased. All the children were stillborn and all the mothers did well.

INVERSION OF UTERUS.—A short abstract of my only case will be given in this report; I have elsewhere reported the case in greater detail (*Indiana Journal of Medicine*, March, 1874):

Mrs. B., aged thirty-three; sixth labor. Without pain, at 3 P.M., the waters escaped, and pains supervened at once. The child, a male, was born at 9.30 P.M. About five minutes later, while making compression over the uterus and slight traction on the cord, the woman lying upon her back, a strong pain came on and the uterine globe escaped from my grasp. An examination revealed the inverted uterus, with placenta still partially attached, lying in the bed between the woman's thighs. I hastily separated the placenta, and indenting the fundus with the tips of my fingers, soon restored the uterus to its place. The hemorrhage was excessive while the inversion continued. So quick was the manipulation that the woman was not aware of the real nature of the trouble until restoration was complete. I did not wait for an anesthetic and the pain was slight. I am confident that the accident was not due to compression or traction, as both were used within proper bounds, such as, both before and since, I have resorted to hundreds of times for the removal of the placenta.

PODALIC VERSION.—I resorted to this operation three times. The first time was to correct a right shoulder presentation complicated with a prolapsed funis. The subject was one of twins. I performed version and saved the child, a female. Immediately a second bag of waters formed, pushing the placenta (a single one), followed by the vertex and arm of the second child. I was unable to extricate it, so I pushed the head back, seized both feet and delivered. I failed to resuscitate the child, a female. Both operations were performed without the aid of an anesthetic; the patient, a stout Irishwoman, persistently refused chloroform. Both operations occupied less than ten minutes. In the third case the left hand and the forearm protruded through

the vulva. Dr. Robert Winton administered chloroform and I performed version at once. The child, a female, was saved. Both women made a quick recovery.

CEPHALIC VERSION.—I had but one case, Mrs. M., in her second labor. She had had slight pains all day when I saw her at midnight. At that time the pains were stronger, but the os would barely admit the tip of my finger. I could not then distinguish the presentation. At 5 o'clock A.M. the os was fully dilated, and I diagnosticated a right shoulder presentation. Being alone in the country I administered chloroform myself and prepared to render assistance. After rupturing the membranes, with my right hand in the vagina, the patient lying upon her back, I pushed up the shoulder; at the same time, with my left hand on the abdomen, I pushed the breech upward and toward the median line of the mother. The manœuvre was easily accomplished, and a pain coming to my assistance, drove the head into the pelvis in the first position. Labor was terminated at 6.30 o'clock A.M., resulting in the birth of a medium-sized male. The mother and child did well.

FORCEPS.—With each succeeding year I resorted more frequently to the use of this instrument. I used forceps 37 times, as follows:

1st	300 cases	1 time,	or 1 in 300 cases.	
2d	300 "	9 times,	or 1 in 33⅓	"
3d	300 "	17 "	or 1 in 17½	"
Last	100 "	10 "	or 1 in 10	"

An average of once in 27 cases. 28 of the women were I-paræ, 3 II-paræ, 3 III-paræ, 2 IV-paræ, and 1 VII-paræ. All the mothers recovered; 31 of the children were alive, and 6 were stillborn. 14 of the children were males and 23 females. I used forceps 4 times for the relief of convulsions, once for a face presentation, once for the after-coming head, and 31 times for uterine inertia and tedious labor.

In a study of my cases I cannot discover any special relation existing between the repeated use of the forceps and stillbirths. In my first three hundred cases I had 10 stillbirths, in the second 11, in the third 8, and in the last one hundred 7. The causes of mortality in the last one hundred, however, will show that the excess was not due to forceps. For instance, 4 of the 7 stillborn children were anencephalic, 1 was due to a very tedious labor, 1 to extremely large shoulders that delayed the labor, and in the seventh case the mother had puerperal convulsions.

I am convinced of the fact that in my own experience infant mortality has been lessened, and maternal suffering has been diminished in numerous instances, by a timely resort to forceps.

COLORED.—Fifteen of the labors occurred with colored women, representing ten persons. One woman I attended five times and one twice. 8 male and 7 female children were born. All the mothers did well and all the children lived.

ILLEGITIMATE.—I met with 8 illegitimate births, all primiparous. Seven of the women were unmarried, and one was married, but living in adultery apart from her husband. 2 of the women were aged fifteen, 1 sixteen, 1 eighteen, 2 nineteen, and 1 twenty-one years. 3 males and 5 females were born, all alive. 7 of the women were white and 1 colored. Two of the women were associates and their labors occurred close together.

DEATH OF MOTHER.—Three of the women died. The deaths occurred respectively, by No., as 69, 360, and 381, so that after my third case I had 619 labors with no death. A short synopsis of the cases is here given:

CASE I.—Mrs. W., primipara, age twenty-one, was delivered after an easy, natural labor, December 19, 1870, at 1 A.M., of a female child. She did well until 6 P.M. of the 21st, sixty-five hours after her delivery, when she went into a severe convulsion. She had a number of light convulsions at irregular intervals afterward and never regained perfect consciousness. She died on the 25th, the seventh day from her delivery.

CASE II.—Mrs. F., third labor, age twenty. This woman was enfeebled by two former abortions at close intervals. At the time of the labor she was suffering from nursing sore-mouth. The labor was easy, and she gave birth to a male child. She gradually became anemic; diarrhea and anorexia supervened, her strength steadily failed, and she died on the tenth day after her confinement.

CASE III.—Mrs. N., primipara, age nineteen, was near her term of gestation. About the middle of the day, March 24, 1877, she was taken with a severe chill, followed by fever. She never felt motion after the chill. Pains began at midnight of the same day. I saw her at 8 o'clock the following morning and the child was born one hour later. It was a medium-sized female, and stillborn. The labor proved to be the initial of an attack of pneumonia that terminated her life eight days after her confinement.

STILLBIRTHS.—Eleven stillbirths occurred in primiparæ and 25 in multiparæ—a total of 36 cases. Sex was represented by 19 males and 17 females. The presentations were as follows: cephalic 30, breech 3, and footling 3. Two of the cephalic and 1 of the footling cases were complicated with a prolapsed funis, and in 1 of the footling cases the cord encircled a thigh. In 1 case the vertex, cord, and hand were in the vagina, and the birth occurred with the arm extended in advance of the head. One presented with head and arm pushing the placenta before them and necessitating turning. Four were anencephalic monsters, and in another case the bones of the head were absent, the scalp hanging in

loose folds. In 4 of the children the cuticle was detached, indicating that they had been dead for a number of days—2 of them being twins. In 1 case, to be again mentioned more particularly, the mother's strength had been reduced by a companion retained fetus. 3 deaths were due to placenta previa, and another to a concealed hemorrhage occurring frequently for several days prior to delivery. In 2 of the cases the mother had convulsions. 1 of the children had an enormous abdominal tumor, probably connected with the liver or kidney. In 2 cases the children were large and the shoulders were unavoidably delayed. In 1 the after-coming head was delayed, requiring forceps. In 1 case the mother had a chill the day before delivery, that proved to be the percursor of a severe pneumonia. In 2 cases the pelves were small. In 2 cases the labors were very tedious. In 2 cases ergot was a possible cause. One might have been averted by use of forceps, but the privilege was persistently refused. In 1 case other stillbirths had occurred.

Deformities.—I met with 4 anencephalic children. The bony structures, except those portions near the base of the cranium, and the soft parts of the cranium, were absent. The brain tissue was merely a small mass occupying the site of the cerebellum and uncovered by membranes. It is remarkable that all the cases were in my last 100—Nos. 904, 932, 937, and 976 respectively. One occurred in a primipara and 3 in multiparæ. One was a male and 3 were females. No communication existed between any of the women, nor did they attempt any explanation for a cause.

In another case the upper cranial bones were deficient, the forehead projecting unusually high, and posteriorly the scalp hung in a loop not unlike the mode of hairdressing known among ladies as a "waterfall." The ears were small and situated on prominences near the angle of each jaw. In 1 case a spina bifida existed in the lumbar vertebræ, both feet were deformed, the frontal bones were wanting, and the right ear was absent, only a trace of it existing at the usual site. The child, a male, lived nine days. I met with 2 cases of single talipes.

Premature Rupture of Membranes.—I have elsewhere entered more fully into this subject: "Is Labor Protracted by Early Spontaneous Rupture of the Membranes?"—*American Practitioner*, June, 1874; and "A Study of the Subject of the Spontaneous Rupture of the Membranes at Full Term of Gestation Preceding the Beginning of Labor," *American Journal of the Medical Sciences*, April, 1885.

In my 1000 cases I met with 75 cases of spontaneous rupture of the membranes at full term of gestation preceding the beginning of labor. This gives a ratio of 1 in every 13½ cases. I have excluded from my list cases of hydrorrhea gravidarum, simply considering true cases of rupture of membranes. No case was counted if a pain preceded the rupture.

After rupture of the membranes pains supervened "at once" in 28 cases; within 4 hours, but not coming for half an hour, 21; from 4 to 24 hours, 15; and after 24 hours, 11.

The 75 women were in labor 603 hours and 5 minutes, making an average of 8 hours and 2 minutes. Twenty-six of the women were primiparæ, and were in labor 265½ hours, making the average duration of of labor 10 hours and 12 minutes. Forty-nine were multiparæ, and these were in labor 337½ hours, averaging 6 hours and 53 minutes. I wish the fact to be noticed that the duration of labor in these cases is exact—more so than in ordinary cases, where, to assume a regularity, we are accustomed to count from the time the pains begin. In these cases the time was noted from the first pain to the expulsion of the child.

There were 41 males and 35 females born. Among the number was a pair of twins. The presentations were: cephalic 71, breech 3, and footling 2. The mortality to the children was 3, or 1 death in 25 births. Of these, 2 were males and 1 a female. All the mothers did well.

Retention in Utero of Dead Fetus.[1]—Mrs. S., aged twenty-three, primipara. When about four months advanced in pregnancy her health began to decline. An irritative cough supervened, with hectic chills, followed by night-sweats, loss of sleep, and general impairment of the vital forces. About one month prior to the time of her confinement she came under the professional care of the late Dr. R. Winton, then my partner. He found her presenting the prominent symptoms of a serious lung disease. Her cough had increased in severity, and was accompanied with a profuse expectoration of thick, yellow-colored mucus. Hectic chills recurred daily, with fever, followed by night-sweats, shortness of breath, etc. Anorexia was persistent. A marked diarrhea was present, the alvine discharges amounting to six or eight daily, unless controlled by opiates. Emaciation was extreme, and her pulse reached 120 to 140 per minute. So feeble had she become that she was unable to quit her bed.

Such was her condition when I was called to attend her in labor. I saw her at midnight, September 14, 1874. The pains were recurring regularly, and with considerable force for her strength. At 2 A.M. a small male child was born. I think it died during the process of birth. Examining for the placenta I felt a flattened object, which I withdrew. It proved to be a dead male fetus, which upon close inspection presented the appearance of one advanced to the fourth month. It had been preserved entire in the liquor amnii, and

[1] See Transactions of the Indiana State Medical Society for 1875, for a fuller consideration of this subject by the author.

flattened by compression between the uterine wall and its companion (*fœtus papyraceus*). The placenta was adherent, and necessitated manual interference. The two cords were attached to a single placenta. The fetus had died about the time the health of the mother began to decline. In a very short time after her confinement she began to improve; the cough abated, the diarrhea ceased, the fever and night-sweats were extinguished, and she was soon restored to perfect health. On March 17, 1876, I again attended this woman in labor. She was in excellent health, and gave birth to a healthy female child.

A second case occurred in a Mrs. M., aged forty-five, multipara. I had not seen this patient until I was called to attend her in labor. I gleaned the following history: For the last five or six weeks she had been troubled with an irritative cough, accompanied with a scanty expectoration. These symptoms had gradually grown worse, and dyspnea was well marked. Anorexia had increased, and emaciation existed to quite a degree; she was also anemic. A slight fever had been present, with an acceleration of the pulse. Pains began at midnight, April 3, 1877, and I saw her shortly afterward. She had last been unwell June 6, 1876, and counting 280 days from that period, she should have expected her confinement March 3d, so that she went twenty-two days over that date. Labor was terminated at 7 A.M. (4th). The child, a male, was stillborn, and putrid. The cuticle was detached in many localities, and the scalp was distended, with fluid beneath it. An odor of putrefaction was present, and the fetus had probably been dead for some time. Convalescence was slow, but she made a good recovery.

PENDULOUS ABDOMEN.—I met with two of these cases, one of slight degree, the other more marked. The latter patient, Mrs. W., aged thirty-six, was taken in labor with her sixth child, December 7, 1878. I saw her on the morning of the 8th, at 6 o'clock. The pains were inefficient, and the os situated high up in the pelvis. When she stood erect, or lay upon her back, the contour of the abdomen was unique. The uterus lay in front of, and projected below, the pubic bones, so that it was difficult to perform the vaginal touch.

At 8 o'clock A.M., the os being well dilated, I ruptured the membranes and liberated a vast quantity of liquor amnii. I was now able to distinguish the right foot and left knee presenting. The belly of the child lay across the pubes, while the head rested over the upper part of the mother's thighs. Of course, in this position the uterus could exert but little force, and the abdominal muscles still less, in expelling the fetus. I kept the patient upon her back, and tightened a bandage about her abdomen. With one hand I drew upon the right foot, while with the other I pushed the head upward. Labor progressed rapidly after this operation, and at half-past 10 o'clock, A.M., a large-sized female child was born, and in a few moments cried lustily. This woman informed me that of her five former labors three were breech or footling cases, and two were "crosswise"—probably shoulder presentations.

PARTURITION AND ERYSIPELAS.—I attended a woman in labor, September 18, 1868, who the day previous had stepped on some broken glass, which lacerated her right foot. On the day following her confinement erysipelas developed in the foot, and extended over the leg and thigh to the body, the disease continuing until the 27th. The skin and cellular tissue sloughed to such an extent that intractable ulcers formed, necessitating the amputation of the thigh months afterward. No puerperal disease supervened. She nursed her child, and both did well.

ANTISEPTICS.—I have never resorted to antiseptics, in the strict meaning of that term, in cases of normal labor. I have used the proper precautions of cleanliness in regard to my person and also my instruments. When in attendance upon severe cases of contagious disease I have refrained from taking charge of obstetrical cases. When the lochia has been offensive I have used vaginal irrigations, but I have regarded the use of vaginal injections after ordinary cases of labor as useless, and possibly harmful. Two years ago I contributed a paper upon the subject of "Antiseptics in Normal Labor,"[1] in which I claimed that antiseptic precautions were not as essential nor feasible in labor cases in the country as in city and hospital practice. In that paper I arrived at the following conclusions, and I am still of the same opinion:

1. The history of obstetrical practice teaches us that the lying-in hospital has always been a place of danger and mortality; therefore, it is obligatory upon those that have charge of these institutions to utilize every antiseptic measure known to the profession in order to save life.

2. The experience of country practitioners teaches us that women that are confined in healthy, isolated rural homes are not subjected to the contaminating influences of an ochlesis, and consequently do not require all the precautions of those exposed to hospitals, or even to the atmosphere of city life.

2. That country practitioners of medicine will generally show a lower rate of mortality in obstetrical cases than city practitioners, simply for the reason that they practice in healthier localities, are less exposed to contagious influences, and, possibly, have a healthier class of patients.

NOTES.

I met with one cord twelve, and another fifteen inches in length.

[1] Transactions of the Indiana State Medical Society, 1889, also, Medical and Surgical Reporter (Philadelphia), June 22, 1889.

I attended a woman twice in labor the same year, January 8th and December 27th.

There was no vesico-vaginal nor recto-vaginal fistula following any of my cases.

I met with two cases of general edema during labor. No untoward results followed.

I met with no severe case of puerperal fever, nor of pelvic complication.

I had one case of morbus ceruleus in an infant, a male. It lived seven hours.

The dorsal posture was the common one for delivery, and always so when forceps were used.

One labor was bloodless. The placenta came away in ten minutes, and my hand was not discolored with blood.

Two of the children on whom I attended at birth I afterward attended in labor. Thus they appear in my tables first as children, afterward as mothers.

I met with one mild case of puerperal mania in a multipara. The first symptoms developed five days after labor, and continued for three or four days.

A right labial thrombus developed in a multipara eleven days before her labor, and continued for five days, when it ruptured spontaneously. The labor was simply more painful.

One woman whom I attended in her sixth, seventh and eighth labors, had a secretion of milk for three days; it then disappeared, and the breasts became flaccid. The same peculiarity had existed in all her former labors.

In 1 case the parents had been married twelve years before pregnancy occurred. In 1 instance sixteen years had intervened since the last labor, and in 3 others thirteen, eleven, and ten respectively.

I attended a woman in labor on the 29th of December, who last came unwell February 27th, and the flow continued five days, ceasing March 3d. From that date to December 29th is 301 days. The date of menstruation was definitely fixed by the death of a relative. The child, a male, weighed 13 lbs. and 9½ oz., on correct scales.

I met one case of spurious pregnancy. The woman was forty-seven years of age, and had borne several children. I was engaged to attend her about the 25th of August. I was summoned on the 12th of October, and informed her she was not pregnant. She had been misled by sensations in the abdomen, which she mistook for fetal movements. She had based her opinion on this sole symptom.

If I place the low estimate of an average of 6 hours with each labor, I spent 6000 hours, or 8 months and 10 days in the lying-in chamber. Such an experience could not but impress me with admiration for the patience and self-sacrifice of woman, doomed as she is to drink deep of the bitter cup of suffering. In the time named I must have witnessed hundreds of times the rapid change from the anguish of distress to the climax of a woman's joy—the first realization of motherhood. I can make no stronger plea for this class of patients than has been made by our own physician-poet, Oliver Wendell Holmes: "The woman about to become a mother, or with her newborn infant upon her bosom, should be the object of trembling care and sympathy wherever she bears her burden, or stretches her aching limbs. The very outcast of the streets has pity upon her sister in degradation, where the seal of promised maternity is impressed upon her. The remorseless vengeance of the law, brought down upon its victim by a machinery as sure as destiny, is arrested in its fall at a word which reveals her transient claim for mercy. The solemn prayer of the liturgy singles out her sorrows from the multiplied trials of life, to plead for her in the hour of peril. God forbid that any member of the profession to which she trusts her life, doubly precious at that eventful period, should hazard it negligently, unadvisedly, or selfishly."

ON THE UTILITY OF SUSPENSION IN DISEASE OF THE SPINAL CORD; ILLUSTRATED BY A CASE.

By DAVID D. STEWART, M.D.,

DEMONSTRATOR OF DISEASES OF THE NERVOUS SYSTEM, AND CHIEF OF THE NEUROLOGICAL CLINIC IN THE JEFFERSON MEDICAL COLLEGE; PHYSICIAN TO ST. MARY'S HOSPITAL, AND TO ST. CHRISTOPHER'S HOSPITAL FOR CHILDREN.

THERE is in medicine a certain class of ill-balanced enthusiasts akin to those that have been aptly styled by Bartholow, "quid nuncs," on whose minds a suggestion of a novel therapeutic method is prone to make an impression like the desert's mirage on the vision of a deluded wanderer astray—conceptions of possibilities impossible. The illogical expectations of this class have not only created illusive hopes in many a sufferer, but have often served to bring discredit and oblivion to measures that, divested of all fanciful expectations, have in them much of good. That this is true of more than one method of treatment, once the fad of the world medical. now only spoken of to be condemned, there is no doubt.

More than two years have elapsed since the suspension-treatment of diseases of the spinal cord was introduced to the profession by Professor Charcot—a sufficient time in which to form a just estimate of its value. As a matter of course, so novel and promising a therapeutic measure for a class of affections so little susceptible of amelioration by any treatment, fathered by so eminent a neurologist as Charcot, not only attracted general attention, but was received almost with enthusiasm everywhere. The lay press vied with the medical press in accounts of the method, and soon the journals teemed with reports of its trial, generally favorable at first, but subse-

quently less and less so, until now it may be supposed that there are few who, if questioned as to its efficiency, would reply other than that it has had a fair trial and "its day."

I publish this note for the purpose of entering protest against this notion, and to urge that a method that can be productive of so much good, even if only in a small percentage of cases, should not be abandoned unless another more efficient can be found to replace it. Suspension has fallen into discredit with many largely because too much was expected of it. I still maintain the opinion I expressed two years ago, when perhaps the first to report a series of cases in which this treatment was tried: "That suspension will, even though aided by wisely directed medical and hygienic means, effect a cure in degenerative diseases of the cord is, I think, doubtful; but, as an adjunct to other modes of treatment, its utility is beyond question." I made no extravagant claims for this measure then,[1] nor do I now. The assumption that non-inflammatory affections due to an actual degeneration of nerve-elements could be vitally influenced by mechanical means, was not to be entertained; but that the progress of the most common of those that, uninfluenced by treatment, are apt to show a progressive tendency, could not infrequently be arrested and a decided improvement accomplished—though arrest and improvement might be but temporary—more promptly by suspension than by any other therapeutic procedure, has been unquestionably shown. That it should be most efficient, and more than palliatively so, in chronic inflammatory and sub-inflammatory affections of the cord, in those in which the diseased process has had its origin in the intertubular tissue rather than in the nerve-elements, its probable *modus medendi*[2] indicates. Cases of ordinary chronic myelitis, of cord-sclerosis, the mode of onset, symptoms, and course of which place them in an intermediate position between inflammatory and degenerative affections, are those most likely to be permanently benefited by suspension. A case of postero-lateral sclerosis, the clinical history of which indicates that it belongs to the latter class, has been under observation for several months, with improvement so gratifying that I shall report it here as an example of what suspension not infrequently accomplishes:

E. R., aged thirty-eight, had been a railroad engineer from early manhood, until crippled by the spinal malady for the treatment of which he came. He had been injured on the road a number of times about the head, body and limbs, but not for several years immediately preceding the onset of the existing trouble. No apparent ill results followed the accidents, and he was in seemingly good health in the early part of 1890, when he first noticed that sensation in the soles of the feet was impaired. This impairment was gradual and progressive until it reached the upper part of the thighs. At about the same time, or a little earlier, his gait became unsteady, especially in the dark. He felt tired in the back and loins on exertion, and the legs were more or less stiff and unwieldy. There were occasional lightning pains in the thighs, but never of great severity. He had been under treatment in the medical clinic of the hospital of the Jefferson Medical College for several months without improvement and was transferred to the neurological department by Dr. Louis Brinton in November. It was then noted that his gait was highly ataxic, and of the sort best described as reeling—an ataxia not unlike that present in cerebellar disease. He was unable to stand or to walk with closed eyes. The lower limbs were quite rigid. The knee-jerk was much exaggerated, but no rectus or ankle-clonus could be excited. The plantar, cremasteric and lumbar reflexes were absent; the abdominal reflex was present; gluteal and scapular reflexes were present on the right side. There was decided plantar anesthesia, and partial tactile loss in the legs extended somewhat above the knees. There was partial anesthesia of the hands and fingers, with some loss of the muscular sense. Pain-sense was everywhere preserved. The plantar temperature-sense was delayed and dulled, more decidedly to heat than to cold. The muscles were large, well-nourished, and without tenderness on pressure. There was always normal faradic and galvanic response. The electrical examination was repeated on several occasions. A dull, aching pain in the lumbar region, with a sense of constriction about the waist and abdomen, had been constant from the first. A hot sponge drawn along the spine gave rise to a burning sensation in this situation. There was some tenderness on pressure over the spinous processes of the lumbar vertebræ. There had been loss of sexual desire and ability to perform the sexual act for about a year. Hearing had been impaired for a number of years. It had improved about a year immediately preceding the onset of the spinal affection, but subsequently again became worse, being deranged in a manner somewhat different from the primary impairment. The patient observed that whispers could be distinguished better than loud sounds, and low tones better than those of high pitch.[1] The eye report by Dr. Hansell was: R. $\frac{20}{XL}$; L. $\frac{20}{XXX}$; pupils react to light

[1] I shall not now revert to the cases first reported. A further account of these, together with a report of others under observation subsequent to the date of my first paper, will be published at a future day.

[2] Separation and breaking down of inflammatory adhesions; relaxing compressed though still healthy nerve-tissue.

[1] Dr. C. H. Burnett recently very kindly made an aural examination. He reported: Left membrana tympani greatly thickened and retracted, lusterless and blue; right membrane similar, though lusterless in less marked degree. Chronic non-suppurative catarrh of both ears; whispers near the ear are better distinguished than the loud voice, and low tones generally are distinguished more readily than high. High-pitched, loud sounds seem to cause an ataxia of appreciation of sound.

and accommodation; visual field normal; venous hyperemia of the right disc; commencing atrophy of the left nerve.

There was no history of syphilis. Treatment by suspension was begun on November 19, 1890, all internal medication being discontinued. The condition of the patient at that time was as narrated. From this date he was suspended three times weekly until about the middle of April, 1891. The suspensions were made as often by the head alone as with the arm and head-supports. When the axillary straps were also used he was always swung clear of the floor, and, after the fifth time, the duration was about five minutes. Improvement began after the fourth suspension, and was continuous. It was most decided as regards the ataxia, the most prominent symptom. After the twelfth suspension he abandoned his stick altogether in walking. About the middle of April, less than five months after the treatment was begun, the ataxia had lessened so decidedly that the patient was able to take a position as switch-tender on the road. Since this date he has presented himself but once weekly for suspension. His gait is now no longer unsteady, unless he walks with his eyes closed or turns suddenly—then there is slight staggering. He is still unable to stand with his feet in juxtaposition and his eyes closed. The back pain and vertebral tenderness were early relieved by suspension and soon disappeared.[1] A hot sponge, drawn along the spine, causes merely a sense of greater warmth in the lower lumbar region (where before burning was felt) than above. Tactile sensation in feet and legs is much improved. The temperature-sense is still imperfect and delayed. The plantar, abdominal, epigastric, gluteal and lumbar reflexes can now be elicited on both sides. The right knee-jerk is slightly excessive, the left is normal. The legs are much more supple than they formerly were. There is slight ataxia in the right hand, but the patient is much less clumsy with the fingers. Sexual desire has returned; the power, only slightly. Hearing seems more acute than it was at first. When spoken to in a high-pitched voice the patient understands better than he did. The eye condition has not improved.

The result of suspension in this case was so decided and so gratifying that I deemed it worthy of special report in connection with the few remarks preceding its narration. It exemplifies what suspension can do. Even if such results are obtained in but a minority of cases, is that sufficient reason for its entire abandonment?

2620 N. FIFTH STREET.

[1] The discomfort about the lumbar spine was nearly always lessened for a number of hours following suspension. I have noticed this in several cases. It is probably due to relief of the congestion and improvement of the circulation in the diseased area as a result of suspension.

A CASE OF SARCOMA OF THE OVARY; OPERATION; RECOVERY.[1]

BY MILES F. PORTER, M.D.,
PROFESSOR OF SURGERY AND CLINICAL SURGERY IN THE FORT WAYNE COLLEGE OF MEDICINE.

MISS J. S., eighteen years old, consulted me on February 13, 1891, stating that for about a year she had noticed that her abdomen was growing larger. Menstruation was regular, though in the preceding few months the discharge lasted longer and "came a few days under time." For about three weeks prior to coming to me she had herself suspected the existence of a tumor in the abdomen. The general appearance was that of health.

On examination I detected a large, solid tumor, extending from the pelvis to a little above the umbilicus, movable, nodular, in front of and unconnected with the uterus, firm and doughy rather than elastic, not tender, and presenting no circulatory sounds. The uterus was retroverted from the pressure of the tumor, but was movable. During the examination the abdominal reflex was so decided as, at first, to be mistaken for fetal movements. Measurements showed the distance from the left anterior superior spine to the umbilicus to be half an inch greater than that from the right to the umbilicus. A diagnosis of ovarian sarcoma was made.

During the week of February 15th, the patient had, with an interval of two days, two attacks of severe abdominal pain, to subdue which required considerable morphine, and which were accompanied by a temperature of 100° F.

March 1. "Every now and then she has had a little sharp pain," which yielded to morphine.

7th. "She has had no severe pain, but has a little pain in the left lumbar region, which she never had before."

24th. Operation at 2 P.M., time, 1½ hours, much of which was taken in closing the wound, which had to be made eight inches long. The tumor removed was of the left ovary, solid and lobulated, with small but vascular pedicle. There were no adhesions; there was some ascitic fluid.

The pulse, which was 130 when the patient was put to bed, gradually grew better, and from the seventh to the twelfth day ranged from 69 to 84, when it went up to 90 and 98, and remained so for several days, although the temperature remained normal; the patient expressed herself as feeling well, and no cause could be found for the trouble. The highest temperature was 100.2° F., on the second day, but in twelve hours it subsided to normal, where it remained thereafter.

When at the end of seven days the stitches were removed, the wound was found practically healed, except at the point occupied by the drainage-tube.

A bulbous tube with lateral perforations, and closed at the end, was used; on its removal on the fourth day it was found that a portion of omentum had slipped through one of the perforations, the liberation of which required quite forcible use of the forceps. This annoyance might have been pre-

[1] Read before the Indiana State Medical Society, June 10, 1891.

vented by the employment of a tube without a bulb, for the latter makes it difficult for one to pack the gauze tightly enough to prevent portions of omentum slipping through the perforations.

The bowels were moved first on the seventh day by means of a glycerin suppository. The abdomen was scaphoid until after the tenth day, when it became more full, but not at all distended, from the resumption of hearty meals.

Two hypodermatic injections of morphine, grain ⅛ each, were given for restlessness, the first at the end of the first day and the other about the middle of the second. The use of the catheter was required but once at the end of the first twenty-four hours.

To relieve thirst an enema of plain water was given seven hours after the operation and was retained. The patient was allowed to sit up on the fifteenth day and on the twentieth went down stairs and into the yard. At the present writing—May 10, 1891—recovery seems perfect.

On macroscopical examination and section the tumor proved to be solid, with two spots of softening, the consistency of which approached that of brain tissue, and one cyst, the size of a hickory nut. The tumor weighed 7½ pounds.

Excepting the consistency which was greater, and the lobulation, the gross appearances of sarcoma as given by Howel,[1] fit this case exactly. He says: "Ovarian sarcomata are not so irregular in their shape as proliferating cystomata, being usually of oval or roundish contour; their surface is smooth, as a rule, and of whitish or pinkish-white color; while in consistence they are generally, though not always, quite firm, the round-celled variety being soft and brain-like."

Microscopical examination of four sections taken from the surface of the tumor failed to show anything but fibrous tissue, but on examining sections of the growth taken from nearer the center we found that we had a round-celled sarcoma. This shows the necessity of examining sections from various parts of a tumor before deciding as to its nature. I am under obligation to Dr. Howard McCullough for his assistance in the examination of the tumor.

The variety of the disease is in itself sufficient excuse for reporting this case; besides, the case is in most respects beautifully typical and at the same time presents some peculiar features.

Greig Smith[2] says: "Of all tumors of the ovary probably not more than 3 per cent. are solid. Most of them are malignant sarcoma or cancer." Skene, in his recent work, says practically nothing on the subject of solid malignant tumors of the ovary. Lee, in his article in the *International Encyclopedia of Surgery*, says: "True sarcoma is yet more rare than pure fibroma." While this statement is not in accord with the opinions of Smith, Tait, Doran, and others, yet it seems borne out by the statistics of Seeger, of Munich[1], who among 13 cases of solid ovarian tumors found 4 of fibroma, 3 spindle-celled sarcoma, 1 round-celled sarcoma, and 5 of solid carcinoma.

The age of the patient, the rapidity of growth of the tumor, its solidity and nodosity, as determined before operation, with the ascites and vascularity of the pedicle, as found at the operation, taken together, made the diagnosis almost certain without the use of the microscope. Then, too, there were attacks of colicky pain, which are so frequent in cases of this kind. One vein in the pedicle was so large as to raise the question as to whether or not it was a part of the small intestine.

I do not know whether the abdominal reflex is apt to be particularly exaggerated in malignant disease of the ovary. Certain it is, that when so marked as it was in this case, it might on hasty examination easily be mistaken for fetal movements. Such a mistake would be still more likely if, with the exaggerated reflex, there was also a vascular bruit, such as is common in solid tumors.

Another rather unusual feature of the case was the location of the tumor, in front of the uterus. While it was possible to move the tumor slightly, the tension of the abdominal walls rendered its mobility much less than would be expected from the absence of adhesions and the length of the pedicle. No lateral enlargement having been noticed and the abdomen being nearly symmetrical when seen by me, I was unable, until the abdomen was opened, to tell from which side the tumor grew. That no tumor was noticed by the patient before the late period indicated seems to me almost incredible.

This was the first time I ever used a bulbous tube, and I shall never use one again, unless no other is at hand, because of the danger of incarceration of the omentum and the great degree of pain occasioned by the enlargement of the opening for the removal of the tube.

I wish to take this opportunity to urge the general acceptance of the doctrine that all ovarian tumors should be removed early. One can never be sure that a given tumor is benign, and besides, a tumor that is benign to-day may be malignant to-morrow. According to Leopold, 22.4 per cent. of all ovarian tumors are malignant, while Schroeder makes the percentage 19.5.[2] From Seeger's statistics already given we learn that in all cases of solid ovarian tumors the proportion is as 9 to 4 in favor of malignancy. The general mortality of the operation for malignant ovarian disease is 33 per cent., while only

5 out of 47 cases were alive and well after three years.[1] According to Beigel[2] "Baker Brown's case appears to be the only one of round-celled sarcoma cured by operation."

While these results are not brilliant, yet it should be remembered that each case cured represents a clear gain of one life. Nor is this all, for in those cases in which there is recurrence after operation "the subsequent course will be less painful than in cases not interfered with."[3]

PERINEAL ABSCESS FROM AN UNUSUAL CAUSE.

BY W. M. L. COPLIN, M.D.,
OF PHILADELPHIA.

ON May 23, 1891, D. G., a laborer, of remarkably vigorous constitution, married, with no history of previous illness, called at my office to consult me about what he termed a burning, smarting irritation of the anus, associated with intolerable itching and pain at stool. He stated that the symptoms came on suddenly, and annoyed him so much that on the previous day he had to give up his work. Upon examination there was slight erosion of the rectal mucous membrane at one or two points, evidently due to the scratching. There was no evidence of fissure, no induration or tenderness in the ischio-rectal fossa nor of the perineum. A saline purge and suppositories of cocaine and tannin, together with an ointment of cocaine and carbolic acid, were ordered. A digital examination of the rectum revealed nothing. On the following day I was called to visit him at his house. The pain had increased, he had slept none all night, had passed no water, and complained of severe pain in the region of both kidneys; at intervals during the night he had vomited freely; his skin was covered with perspiration, and he had considerable headache. The rectal symptoms had not abated, and upon examination nothing further could be elicited. Percussion over the bladder showed it to be empty. This was verified by the introduction of a soft catheter and the withdrawal of about one-half ounce of thick mucus, but no urine. The perineum seemed hard, and on deep pressure somewhat tender. I re-introduced the catheter to find just where the obstruction was, and found that the instrument met with no resistance until after the membranous portion of the urethra was reached, at which point the patient flinched, and considerable force was necessary to secure complete introduction. The patient was seen the same evening, and the symptoms not having abated, his consent was obtained for an operation on the following day. With the assistance of Dr. Hearn and Dr. Wilkinson I operated as follows: The patient was placed in the lithotomy position, the perineum and adjacent parts shaved, and some induration was found slightly to the right of the raphe, and extending across the median line about midway between the rectum and the scrotum. There seemed to be slight fluctuation, but of this I was not positive. The incision was exactly that made in left lateral lithotomy, and was extended well backward toward the rectum and slightly to its left. The incision was slowly increased in depth until it was one and one-half inches deep, when a small amount of gas escaped, followed by a free exit of pus. The opening was enlarged by Hilton's method until two fingers could be easily introduced. This allowed of free exploration, which developed the fact that the abscess extended beyond three and a half inches, up between the rectum and nearly around the latter organ. The prostate was entirely bare, and the urethra, at least one-half exposed, could be felt in the membranous portion. In making this examination a firmly adherent foreign body was detected at the extreme upper margin of the cavity. This, with great difficulty, was detached by the finger-nail and removed by means of an ordinary hemostatic forceps. It proved to be a fish bone, one and one-sixteenth inches in length, at one end sharply pointed like a needle. Careful examination did not reveal where the bone had made its exit from the alimentary canal. The wound was washed out with a 1 : 1000 corrosive sublimate solution, and packed lightly with bichloride gauze; a 1/3 grain morphine suppository was introduced into the rectum, and the wound covered with a large bichloride gauze pad, retained by the ordinary T-bandage. The operation was completed at 4 P.M., at which time but two ounces of urine were drawn off. At 6 P.M. I drew off fourteen ounces, and at 2 A.M. the following morning he voided twelve ounces more. Since then the catheter has not been used. He is progresssing nicely, and sleeps and eats as if nothing had happened.

The noteworthy points in this case relate to (*a*) the cause; (*b*) the location; (*c*) the effect upon the excretion of the urine.

(*a*) Foreign bodies in the rectum are not uncommon, the folds of Houston[1] being well adapted to their arrest and subsequent ulceration into the peri-rectal tissues. As a rule, when perforation occurs the ischio-rectal fossæ suffer, and the perineum rarely, although such cases are not unknown; fortunately, however, this perforation is low down, and rarely affects the bladder and its appendages. When we take into consideration the quantity of fish consumed, and the probable number of bones that accidentally pass into the stomach, one must consider it fortunate that these cases are not more common.

(*b*) The location of an abscess beginning so high up between the bladder and the rectum presents some points worthy of consideration. When it is remembered that the bladder is covered very low down by the peritoneum one cannot but be struck by the dangers of abscess arising so high up. This is more especially the case when the cause is one

[1] Dub. Hosp. Reports, vol. v., p. 163.

that may perforate the bladder itself, thus adding a serious complication to the already infected tissues. The dangers are further increased by the process being above the tense bands of perineal fascia, thus binding the accumulated pus above the most favorable seat for egress, and leading to its upward burrowing and honeycombing the perirectal tissue without presenting as an abscess, either perineal or ischio-rectal—for in this case the only evidence of an abscess was deep-seated induration, no superficial redness, edema, or fluctuation; indeed, there was an absence of all local inflammatory symptoms.

(*c*) The effect upon the discharge of urine. In the ordinary acceptance of the word there was not retention of urine; still, according to a truer conception, retention was present. The pressure upward and forward had occluded the ureters and led to retention above that point, thus producing the excruciating pain in the region of the kidney, and leading to other symptoms. It is possible that a case might present itself in which the retention in the ureters and above might lead to more severe systemic conditions, with less local evidence. In case of inflammation high up between the rectum and bladder, the character of the pain might lead us to suspect either acute inflammatory changes in the bladder or the lodgment of a renal calculus in the ureter at that point. Such an error in diagnosis would certainly lead the patient into danger that might not be seen until serious injury had been done. The probable establishing of suppurating conditions so near the recto-vesical fold of the peritoneum might lead to infection of the general cavity, with the inevitable consequences.

In the estimation of the writer the conclusion to be arrived at is, that all such conditions should receive early and prompt treatment, seeking if possible to find the cause and remove it if feasible, and certainly to release the tension of the perineal fascia. It is unnecessary to mention the promptness with which the surgeon attacks suspected ischio-rectal suppuration, and cases such as the one here reported most certainly demand equally prompt attention, exploratory incision being perfectly justifiable, indeed demanded, in all doubtful cases when the symptoms are increasing in severity or are even stationary.

IT is the common every-day ailments and their effects and treatment that the student wants to become familiar with at first, rather than the rare cases. Cases of colic, of effects of over-eating or drinking, of sore-throat, croup or diphtheria, or scarlet fever, or mumps, of the ordinary fevers, of simple fractures or dislocations, of bad cuts of the palm of the hand, are far more important to him from a business point of view than brain tumors or ligations of the innominate artery.—JOHN S. BILLINGS, "*Ideals of Medical Education.*"

ORIGINAL LECTURE.

MITRAL STENOSIS—HEMIPLEGIA—ATHETOSIS—HEART-FAILURE AND PREGNANCY—TYPHOID FEVER—LOCOMOTOR ATAXIA.

Abstract of a Clinical Lecture
Delivered at Bellevue Hospital, New York.

BY E. G. JANEWAY, M.D.,
VISITING PHYSICIAN.

MITRAL STENOSIS.

GENTLEMEN: Our first patient is a woman, thirty-eight years of age, who has not had rheumatism, chorea, scarlatina or pneumonia, yet she has been troubled with cardiac palpitation on slight exertion for a period of eighteen years. Her sister and mother both suffered from heart disease. She has been married, and has had two children. On examination we find that the apex-beat is carried a little to the left and upward, but the upward displacement may be due to lying on her back. Palpation shows the beat of the left ventricle to be about normal, but that of the right ventricle is increased. On auscultation I hear a mitral presystolic murmur, which is also heard at the back, and the pulmonic sound is intensified. The patient came into the hospital, not on account of the heart trouble, but for a synovitis of the knee, which is apparently of rheumatic origin. In her childhood, she may have had that peculiar condition of the heart that is so often associated with rheumatic constitutions. Children of this type often have a distinct murmur over the heart, and will frequently suffer from what are called "growing-pains." Her mitral stenosis is compensated for, and is therefore not troubling her. Along with the administration of the usual anti-rheumatic remedies, which are indicated in this case, we shall give her iodide of potassium, since there is a suspicion of inherited syphilis.

HEMIPLEGIA.

This man has paralysis of the right arm, that has developed since his admission to the hospital. No satisfactory history can be elicited from him. Auscultation of the chest reveals a distinct systolic thrill, a loud, rough murmur at the apex, heard also behind, and a slight systolic murmur at the base. The thrill is felt over the left ventricle. It is very probable that a vegetation, breaking loose from the heart, has plugged up a blood-vessel in the brain, and it is quite possible that the mischief so produced has been still further increased by a thrombosis. You notice that there is great rigidity of the neck, and this is commonly considered to be indicative of meningitis. It is not always so, however, for I have seen it in edema of the brain in alcoholic subjects, in patients with cerebral tumor, and in cases of abscess of the sphenoidal lobe. If this case be one of meningitis, it is probably secondary to embolism and consequent cerebral softening; or the irritation so produced might account for the rigidity. Let us look for further evidences of embolism. We find a few petechial spots on the limbs and body. As the tongue is an organ that is *pushed* out by muscles, it deviates *toward* the diseased side, and in this case it is more markedly affected than the face. There is a little dribbling of saliva on one side, and the paralysis is rendered much more evident

by asking him to drink a little water, when the dribbling of water from the paralyzed side becomes quite apparent.

ATHETOSIS.

Let me now show you a man exhibiting that peculiar condition usually spoken of as athetosis, but more accurately described by the name, post-hemiplegic chorea. Sometimes this condition is the result of a strain upon the vessels of the neck, and sometimes, and not uncommonly, it is due to hemorrhage consequent upon forceps delivery. This man says that he was "born paralyzed," and so it is probable that at the time of delivery there was a hemorrhage into or upon the brain, that gave rise to his trouble. You notice that there is no weakness about the muscles of the right arm, the one affected, but, on the contrary, they are well developed. But on endeavoring to grasp an object with the right hand, there is a want of coördination between the different sets of muscles, and the flexors overpower the extensors, giving rise to a peculiar twisting of the hand and a stretching forth of the finger. There is also a slowness in the volitional movement, and a choreiform agitation. There is no special difference in the patellar reflexes. There is probably a sclerosed area on one side of the brain, and a more diffused impulse goes out from the brain than is normal. Medication is, of course, of no avail.

HEART-FAILURE AND PREGNANCY.

Our next case is that of a woman, who says she is thirty years old, although her appearance would indicate that she was about forty-five. It is impossible to obtain a very satisfactory history from her, but since she has been in the hospital she has had three attacks of heart-failure, with congestion and edema of the lungs, each of which has lasted for some time, and has been accompanied by bloody, frothy expectoration, and a rapid, feeble heart. The first attack lasted twenty-four hours, the second, two days, and the third, twenty-four hours; and in each instance she was promptly relieved by the administration of stimulants. I saw her in one of these attacks, when there was cyanosis, with a rapid, feeble heart-action, and an abundance of moist râles in the lungs. She is six months pregnant, and she tells us that about three years ago, when at the same period of pregnancy, she was troubled in the same way. These seizures are typical of a class, of which I have seen several examples, in which there was mitral stenosis.

On examining her, I find an intensified second sound, which is important as indicating increased tension in the pulmonary system. When examining her yesterday, I found a distinct systolic murmur at the mitral orifice, and the probabilities would favor the existence of this condition; but to-day I hear no distinct murmur at this point, and at present there is only a want of compensation that, with the coexistence of pregnancy, would explain the feebleness of the heart. To make an absolute diagnosis, it would be necessary to watch her from day to day for some little time. I saw last night in private practice a patient, also pregnant six months, who had fluid in both pleural cavities, and, as in this case, an intensified pulmonic sound. Two doses of digitalis brought the heart down from 90 to 80, cleared up the edema of the lungs, and brought out a well-marked presystolic murmur at the mitral orifice, indicating mitral stenosis. Of course, in considering the matter of treatment, the question of the advisability of inducing premature labor presents itself, and it is one that is difficult to answer; so many delicate questions are involved in it that each case must be carefully decided upon its individual merits. Since this patient has been in the hospital, digitalis has been freely administered, and it has controlled the rapidity of the heart's action and has diminished the pulmonary congestion. Hot applications have also been used over the region of the heart.

TYPHOID FEVER.

I would call your attention next to this man, who is a waiter by occupation, and who, on admission, gave a history of having been sick for about fourteen days with fever, chills and constipation. On admission, his pulse was one hundred, and his temperature 105°, but later in the day his pulse went down to 78, and since then has been a little higher. The day after his admission two or three spots of roseola were found upon the body. The spleen was also found to be enlarged. A dose of castor oil was followed by diarrhea. The last temperature noted is 102°, and only once has it been below 103°. We have, then, a history of continued fever, of splenic enlargement, and of a rather excessive action from an ordinary dose of castor oil. Since his admission he has had yellow diarrheal movements. His tongue is only moderately coated. You notice that his face is flushed and somewhat mottled. By drawing a line with the finger on the skin of the forehead, a red line slowly develops, and this can be observed on other parts of the body. Now, this phenomenon has been looked upon by some observers as pathognomonic of meningitis, and it is therefore often spoken of under the name of the *tache cerebrale*. But, although it is commonly found in cases of meningitis, it is also not unusual to find it in pneumonia and in typhoid fever; and it would have been found in these diseases long ago had it not been that no one thought of looking for it in these conditions. This patient shows this test pretty fairly, and yet there is no evidence of meningitis; there is no rigidity of the neck, and his mental condition is pretty fair. This sign, considered by many so important a factor in the diagnosis of meningitis, is utterly fallacious. This patient gives us the history and signs of a fairly plain case of typhoid fever. I wish you to notice that there is no herpes on his lips. Herpes may be found in a great many febrile conditions, but it has been my experience that it is not seen in typhoid fever; in fact, if I found herpes present, it would require very convincing evidence to make me believe that I had a case of typhoid fever to deal with. This patient has been taking a moderate quantity of stimulants. If his fever remain rather high, I would advise the systematic employment of baths, beginning with a temperature of 96°, and cooling it down to 70°, or placing him in a bath at 70° for about ten minutes, and then taking him out and rubbing him down thoroughly to favor reaction. These baths effect an immediate reduction of the temperature, and subsequently a still greater reduction. In considering the question of diagnosis, you may have noticed that I did not examine for gurgling in the iliac region, and I omitted it intentionally. It is unwise to teach students to make pressure in the iliac region in order to elicit this sign, for the ulcers

are sometimes deep, even at this stage of the disease, and a little rough or careless manipulation may very easily cause rupture of the intestine. It is better not to employ this test, as the diagnosis can be made in other ways.

LOCOMOTOR ATAXIA.

Let me now for a moment direct your attention to this woman, who comes to us complaining of sharp, localized pain over the right temple, and with a history of having suffered from migraine or sick-headache for a period of many years. Most physicians would at once think of prescribing antipyrine, antifebrin, exalgine, or some medicine of that class, and nitro-glycerin is a favorite remedy with many. But in such cases as this, where there is flushing of the face, you should not use a remedy like nitro-glycerin, that dilates the capillaries; on the contrary, ergot would be more appropriate. But in addition to this patient's headache, she presents other important symptoms. The patellar reflex is absent, there is inability to stand with the heels together and the eyes shut, and in walking she constantly watches the movements of her feet. Sensation in the feet is both delayed and diminished, and an area of tactile anesthesia is distributed irregularly along the fingers of both hands. This patient has locomotor ataxia, and she comes of a somewhat neurotic family. We shall make use of no medication directed toward relieving the locomotor ataxia, but we hope to relieve some of her symptoms by a course of suspension, carried on in a manner similar to that employed when one of Sayre's plaster-of-Paris jackets is applied. The case will be watched with interest, and I hope in a few weeks to be able to show what results have been obtained by this method of treatment.

CLINICAL MEMORANDUM.

INTRA-LIGAMENTOUS CYST, WITH TWISTED PEDICLE, CAUSING INTESTINAL OBSTRUCTION; LAPAROTOMY; RECOVERY.[1]

BY THADDEUS A. REAMY, M.D.,
OF CINCINNATI, OHIO.

THE following communication from Dr. A. B. Isham, of Cincinnati, furnished by request, properly introduces and becomes an important part of this brief report:

"In the forenoon of December 15th I was called to see a young lady, aged twenty years, of ruddy complexion and exceptionally fine physique, who gave the following history: On Wednesday afternoon, December 10th, while dressing, she had sharp abdominal pain, between the umbilicus and pubes, which gave great distress for some minutes. She felt a sense of uneasiness afterward, but was not much disturbed until in the night, when she was taken with vomiting, severe abdominal pain, and had several small, thin discharges from the bowels. There was great abdominal soreness on the 11th, 12th and 13th, which diminished on the 14th, so that she was able to dress herself and sit up. At the time of my visit on the 15th, she was prone upon her back, with the knees drawn up; she had an anxious expression of countenance, and exhibited very great tenderness to touch and pressure over the abdomen, particularly in the right iliac region, where there was a hardened mass of considerable size extending beyond the median line to the left side; the abdomen was somewhat tympanitic. The temperature was 100.5°, the pulse 110. I took it to be a case of appendicitis, with fecal impaction of the cecum, and ordered one pint of olive oil to be taken in four hours, in divided doses of two ounces every half-hour. At my afternoon visit the oil had all been taken, but without effect. I administered four injections of two quarts each of warm water, which came away slightly discolored, but brought nothing with it. I then ordered Epsom salts in teaspoonful doses dissolved in warm water every hour. In the night the salts were vomited, and further administration was stopped. Tuesday morning, December 16th, the pulse was 120, the temperature 101°, the tenderness and tympanites increased, and no stools. I administered more two-quart injections of warm water, without result except that oil globules floated upon the surface of the water returned. The temperature was now 102°, pulse 125. I announced that in all probability surgical operation was the only resource, and asked for consultation with Dr. Reamy, which was assented to. The consultation was held at 3 P.M., and operation decided upon, awaiting, however, the parents' consent, who were at Marietta, and had been telegraphed for. A hypodermatic injection of morphine was given to quiet the patient, under which she rested quietly up to the time of the operation at 9.30 A.M., December 17th."

As stated by Dr. Isham, the patient was a young woman of perfect form and physical development. She was at the time of the attack in robust health. Her menstruation had been painless and normal. She had not noticed any change in her size or form. Neither her under-clothing nor over-clothing had been altered to conform to any demand in this direction. These facts are somewhat striking in the light of the following disclosures:

Laparotomy: There were present and assisting, Drs. Isham, E. W. Mitchell, W. D. Porter and Charles L. Bonifield. Etherization was without difficulty, and a median incision three and one-half inches in length was made. Some bloody serum escaped from the peritoneal cavity. I found a cyst, which proved, on removal and examination, to be intra-ligamentous, and arose from the left broad ligament. It was twice as large as my clenched fist, and was markedly lop-sided, though not lobulated. Its pedicular attachment was very near to the uterus. Its pedicle seemed so short as to render lifting it out impossible. The shortness of the pedicle was subsequently found to be due to a twist of the same. The cyst was opened, and partly coagulated and fluid blood, with the ordinary fluid found in intra-ligamentous cyst tumors, was turned out. At one point, near the pedicle, a small rupture had occurred in the wall of the cyst, through which some blood and other fluid had escaped into the peritoneal cavity. Even after the cyst was emptied, it had to be turned once around so as to untwist the pedicle before it was long enough to allow of ligation. It was ligated with silk, the cyst cut away, and the pedicle dropped. The ovary was not enlarged, nor apparently diseased, but the Fallopian tube was somewhat distended. I removed the left ovary and tube.

The mystery of the case was now cleared up. I have

[1] Read before the Mitchell Medical Society, July, 1891.

already spoken of the tumor as lop-sided. Its chief growth had been rapid, and, of course, recent, and was due to the twisting of the pedicle, which was so complete and sudden as not only to arrest the venous return of blood from the tumor, but to cause hemorrhage. Its sudden tension and rotation under these circumstances carried its larger projection over to the right side of the abdomen, where it pressed upon, displaced and completely obstructed the cecum, colon and ileum. It had crowded the cecum and ileum out against the iliac bone. It had gone under and behind the ileum and cecum, pushing the former up alongside of the ascending colon; indeed, it may be said to have lain parallel with the ascending colon, while the cecum was pushed up at an acute angle with the colon. The greatest flexure was thus at the point of entrance of the ileum with the large intestine.

It is scarcely necessary to add that these flexures resulted in complete obstruction of the ileum and large intestine. The mass was large and firm. The cecum, colon and ileum were quite discolored, showing the effects of strangulation. The vermiform appendix, in this instance about three and a half inches in length, was turned upward in front of the cecum, and was somewhat unhealthy. It was by no means so deeply discolored as the cecum, ileum and colon. It had probably been displaced forward, out of its usual position behind the cecum, during the rapid invasion by the tumor.

The extent and character of the displacements here described would seem almost incredible in view of the fact that both cecum and colon were filled with fecal matter, and that the ileum was likewise much distended. The condition is all the more difficult to comprehend when the anatomical facts are recalled that notwithstanding the lower end of the cecum lies free in the abdominal cavity, and is susceptible of considerable mobility, yet it is completely invested by peritoneum that is reflected from its sides on to the posterior abdominal wall. It is almost incredible that under the circumstances it could have been forced up as it was.

Irrigation of the abdominal cavity with warm water was immediately commenced. During the process, with my fingers through the incision, I restored to mormal position the displaced portions of the intestine, and made gentle upward pressure upon the colon and cecum, with slight compression. At the same time, Dr. Isham injected warm water into the rectum, the patient having been drawn to the end of the operating-table. Immediately, I could feel the fecal masses ascending the colon, and soon all was clear, copious stools immediately occurring.

The obstruction removed, the discoloration of the intestinal walls could be seen through the abdominal incision rapidly subsiding. Undoubtedly, the warm water aided in this result. A glass drainage-tube was inserted and allowed to remain thirty-six hours. The abdominal wound was closed with silk sutures, adhesive straps were applied, and dry pads of cheesecloth, without antiseptics, with bandage of the same goods, furnished the dressing. Recovery was uneventful and complete.

REMARKS.—The clinical history of this case presents some facts that command consideration. In my judgment, the most important is that not from choice on the part of Dr. Isham and myself, but from necessity (waiting for the arrival of the parents and their consent), the operation was postponed twelve hours from the time that we considered it imperative. It is needless to add that we believed each of these hours a serious loss of chances for success. Whether this is true is now subject to doubt. When we left the patient in the evening, the pulse was rapid, irritable, the temperature high, the countenance anxious, markedly pinched, the breathing rapid, the pain excruciating, the abdominal distention well marked. Under a full dose of morphine, hypodermatically, six hours of uninterrupted and deep sleep followed, so that in the morning when we arrived for the operation, the patient was free from pain, and the countenance bright and hopeful. Tympanites had somewhat subsided, the pulse was reduced, and the temperature lowered. All this under morphine and with the bowels hopelessly obstructed. It is my belief that the chances of recovery were improved by the delay and the morphine. Much care must be taken in weighing all the facts in any similar case before arriving at conclusions.

As I think, with more reckless audacity than cool judgment and good breeding, some operators now denounce and brand as coward any surgeon who advocates waiting in any case where the necessity for a laparotomy seems to be probable. They argue that delays are always dangerous, and in such cases do they especially denounce under any pretext the use of opiates.

I think that this case is very instructive. It certainly shows that even in a case where the only possible chance of recovery is a laparotomy, there may be safety in delay.

Though I have seen several examples of twisted pedicle in ovarian tumors, this is the only example seen in an intra-ligamentous tumor. I think such accidents to this class of cysts quite rare. In any case, since twisting depends upon dragging, it is exceptional to find twisting of so short a pedicle.

Again, since an unusually large bloodvessel entered deeply into this tumor, as shown on examination of the pedicle, it is interesting to inquire whether all the hemorrhage that occurred took place after the twisting and strangulation, or whether sudden hemorrhage may not have taken place into the cyst prior to the twist, causing a sudden and irregular dilatation of the cyst, which, in turn, caused the rotation.

The case also illustrates the fact that growths in the pelvic cavity may attain a considerable size without impairment of health, without local or constitutional symptoms, or anything, indeed, to attract attention to their presence. It must not be forgotten, however, that the increase in size from the strangulation was probably marked, therefore the tumor, previously, comparatively small.

Finally, the case emphasizes the difficulties and uncertainties of diagnosis. The clinical history and physical examination alike pointed to acute appendicitis, with inflammatory obstruction of the cecum.

THE cost of the paupers in the public institutions of New York in 1890 was $1,949,100. The cost in private institutions from public funds was $1,845,872, making a total of $3,794,972.

CURRENT LITERATURE.

CEREBRAL ACETONEMIA IN A CASE OF ACUTE ARTICULAR RHEUMATISM.

Talamon (*La Médecine Moderne*, No. 14, 1891) states that since the appearance of the papers of Petters and Kaulich, a group of nervous symptoms comparable to those of uremia has been described under the name of acetonemia, a condition characterized by a reddish color imparted to the urine on the addition of perchloride of iron, and by the peculiar acidity of the breath, which exhales an odor that has been compared to that of chloroform, and which, in reality, is the odor of acetone, or of ethyldiacetic acid. Petters, Kaulich, Cantani, Küssmaul and Lecorché have admitted that the nervous symptoms were due to acetone acting upon the organism in the same manner as chloroform. This opinion has been combated by Jaksch and by Frerichs. The precise pathogeny of this toxemia, however, has not been chemically elucidated any more than has that of uremia or of cholemia. The substance which, with the perchloride of iron, causes the red reaction in the urine may be ethyldiacetic acid (Gerhardt), or diacetic acid (Jaksch). The symptoms of poisoning may result, not from the isolated action of one of these substances, but from a series of chemical decompositions, of which the acetone and diacetic acid are but ultimate products of little importance. The solution of the chemical problem of uremia is not more certain; urea plays but a small part in the genesis of the phenomena called uremic; this need not, however, preclude the description and distinction at the bedside of the morbid phenomena grouped under this name. It is just as incontestible that there exists a clinical condition characterized—1. By various nervous phenomena; 2. By a special reaction of the urine; 3. By an odor of acetone in the breath—a group of symptoms that, whatever their real pathogeny, may be comprehended under the name of acetonemia.

Acetonemia has especially been observed in diabetes and in diabetic coma. Petters and Kaulich have, however, noticed that the odor of the breath and the reaction of the urine are observed, not only in diabetics, but also at times in the course of the eruptive fevers, in children with measles and scarlet fever. The researches of Jaksch have confirmed this observation, and have shown that normally the blood and the urine always contain traces of acetone, the quantity of which may be increased in the pyrexias and in different chronic maladies, particularly carcinoma. Jaksch recognizes three varieties of acetonuria: the diabetic, the febrile and the carcinomatous. According to him the nature of the febrile process is a matter of indifference; he has noticed acetonuria in pneumonia, typhoid fever, in acute articular rheumatism, and in the eruptive fevers. He has even observed pronounced acetonuria in a case of mania without fever. Acetonuria or diaceturia may thus exist without acetonemia; in other words, the red reaction of the urine with the perchloride of iron may be produced in the absence of symptoms of acetonic toxemia.

Talamon relates the case of a girl of fifteen, with a history of an attack of acute articular rheumatism with endocarditis, who six years previously was seized with intense fever. On the fifth or sixth day the temperature reached 105.8°, and the girl presented a condition of marked nervous excitement and delirium, almost maniacal. This delirium, characterized by incessant agitation and terrifying hallucinations, coincided with an odor of acetone in the breath and a ruby-red reaction of the urine with the perchloride of iron. It lasted five or six days and disappeared synchronously with the disappearance of the odor of acetone in the breath. At the expiration of some days a second articular attack followed, quite as intense as the first; but the odor of acetone did not reappear and the delirium was not produced. Talamon believes that the acute delirium in the first event was related to the odor of the breath and to the reaction of the urine, and that it is to be attributed to cerebral acetonemia.

There are, however, certain objections to such an hypothesis. The delirium may have been toxic, a result of the action of the salicylic acid administered. Talamon, however, is skeptical as to the occurrence of such a delirium in an adult, and more so in the case of a child. Conceding, however, that such a delirium may occur, in the present instance the patient was already in a state of abnormal over-excitation before the administration of the drug was begun, while the drug was continued without change of dose and the delirium was not only not aggravated but disappeared at the end of some days. In the second event the same dose (90 grains of sodium salicylate) was taken for six days without the appearance of any phenomena of delirium. Again, the delirium may have been a manifestation of cerebral rheumatism. Delirium may occur in connection with hyperpyretic rheumatism, or with rheumatic meningitis. The latter can be excluded by the symptoms. As to the former, the temperature was not unusually high. Contemporaneously with most of the delirium, the condition of the patient was almost apyretic.

From a study of the case reported and from a review of the literature of the subject, Talamon concludes that —(1) Certain of the nervous phenomena that appear in the course of acute febrile diseases may be attributed to acetonemic intoxication; (2) These acetonemic phenomena, which in one case were gastro-intestinal, with collapse and somnolence, and in another included delirium with excitations and hallucinations, are characterized by the peculiar odor of acetone in the breath and the ruby-red reaction that the urine presents with the perchloride of iron; (3) The delirious acetonemia of articular rheumatism may simulate cerebral rheumatism, from which it is to be distinguished by the absence of hyperpyrexia and by the characteristics of the urine and of the breath.

RETENTION OF URINE OF NERVOUS ORIGIN, AND VESICAL NEURASTHENIA.

Guyon calls attention to the large number of patients consulting the surgeon, who complain of constant difficulty in micturition, but who present no appreciable lesion of the urinary apparatus. Patients with well-defined lesions in the urinary tract are often utterly unable to evacuate the bladder, and suffer retention of urine, more or less complete. On the other hand, such a degree of functional impairment is exceptional in those in whom no lesion is detectable, although appreci-

able derangement of micturition may be present. Guyon reports three illustrative cases that have recently come under his observation, two in men and one in a woman. In the case of the first man, thirty-four years old, there was a history of gonorrhea six years previously. Two years prior to his admission into the hospital he had acute retention that yielded after some hours of manipulation with a fine bougie. Since then he had urinated with difficulty, the urine passing in a small stream. The symptoms increasing, he entered the hospital after not having passed urine for thirty hours. On passing a sound, it was found that the anterior portion of the urethra was free, but that the instrument was arrested beneath the pubes, and it was only after repeated efforts that a filiform bougie could be introduced into the bladder. The urine that was discharged was perfectly clear. Examination showed that the testicles, the epididymis, and the deferent canal were in a normal condition. The prostate was small and nodular; the seminal vesicles were also nodular. There was manifestly a profound genital tuberculosis without involvement of the testicular apparatus. Guyon, who never fails to make rectal examination in cases of this kind, has a number of times made similar observations, which are not in accord with the views of surgeons generally, who claim that genital tuberculosis begins in the epididymis. By rectal touch a more thorough investigation of vesical sensibility is possible than by any other means. In the case in question, there was no cystitis and no urinary tuberculosis. The existence of genital tuberculosis, however, was positive. An examination of the bladder was made by means of the manometer of Duchastelet, and a lessening of the vesical sensibility was found, together with a very notable diminution in the contractility of the bladder. An examination of the nervous system did not reveal any somatic nervous stigmata, but revealed a neuropathic condition that was made evident, among other phenomena, by an excessive sensitiveness, so marked that the patient was moved to tears upon being interrogated. The patient also gave a history of hereditary tuberculosis. Urethral spasm was evident, and was associated with a symptomatic spasm, probably dependent upon a genital tuberculosis. The retention of urine was of nervous origin, the vesical sensibility not being exaggerated.

In the case of the second man, there had for a year been difficulty in micturition of gradually increasing intensity. He could with difficulty urinate in a stooping posture; to induce a more abundant expulsion of urine, while still in the stooping position, he was compelled to exert firm pressure with the hand upon the perineum, at the same time bending forward. There was no evidence of a medullary lesion, no anesthesia, no hyperesthesia, no modifications of sensibility, no history of inherited disease. The patient, however, had always been subject to intense pains in the head. He had frequent attacks of depression and melancholia, without any appreciable cause. Most careful examination failed to detect any disease of the urinary apparatus. The membranous portion of the urethra was not abnormally resistant. The urethra was perfectly normal, the prostate pliant and not enlarged. The bladder, examined with a metallic sound, was scarcely sensible to pressure and permitted distention. It emptied itself imperfectly and slowly without propulsion. Its contractility was undoubtedly enfeebled. There was no doubt that the trouble in this patient was nervous in origin—in other words, that it was an instance of true hysterical retention of urine.

From these cases it is evident that in man the retention of urine may be due to a spasm of the membranous portion of the urethra, but it remains to be proved that this may also be the case in women. This spasmodic condition may coincide with a diminution of the contractile power of the bladder. Hence, in the investigation of urinary retentions of nervous origin, a study of the vesical contractility should not be neglected. The participation of the bladder in the production of derangements of micturition is beyond doubt. This participation is, moreover, evident and always of great importance in other varieties of retention. The influence of nervous diseases, either slight or grave, upon the vesical contractility seems to be incontestable. Although the researches in this direction that have been made are far from complete, they already appear demonstrative. Various visceral neurasthenias have been described, including genital neurasthenia, but so far as is known a vesical neurasthenia has not yet been made the subject of any particular investigation. From its frequent occurrence and distinct clinical manifestations, it appears proper, however, henceforth to give it a place in the category of the visceral neurasthenias.—*Annales des Maladies des Organs Génito-urinaires*, March, 1891.

IT is not more than a hundred years ago that medicine claimed to have been a liberal calling, an intellectual pursuit, and even to-day its position as such is very inadequately recognized by the mass of educated men. Now, I venture to say that, as medical education is now given in the best schools, no profession has a better right to claim the title of an educated, intellectual calling, and no men have a better right to demand recognition as intellectual men, as men of trained reasoning faculties, than the physicians themselves. I see, in my position at the head of the university, which includes the department of liberal arts and several professional departments, that the educated community does not recognize this. And I exhort you, gentlemen, in all your various fields of influence to do your utmost to establish this just claim of the medical profession to the position of an intellectual calling and to establish the claim of this great body as a body of highly trained men who use to the best advantage for the community the reasoning faculty, the scientific power of the human mind.—CHARLES W. ELIOT, *President of Harvard University*.

I WELL remember the words spoken by President Eliot, if I mistake not, precisely twenty years ago, at this anniversary dinner, on the matter of the introduction of the three-years' graded course—words which have come true once, and which will again: "The first step toward obtaining an endowment is to deserve one." Our admirable new building, and subsequent gifts, are the proofs. We are sure, should we suffer in our efforts to do our duty by the community still more fully, that the community, and especially the profession, will stand by us.—DR. THOMAS DWIGHT, *of the Harvard Medical School*.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, SEPTEMBER 12, 1891.

COMMERCIALISM AND THE MEDICAL NEWS.

IN various ways, devious or direct, pert, pertinent, or impertinent, THE NEWS is being asked, or rallied, as to its future action under the threatenings of the homeopaths. It is said, and the inference seems logically justified, that these purpose a "boycott" of the works of the publishing house that issues THE MEDICAL NEWS, and that dire things mysterious and awful are impending—all because of a frank editorial criticism of the work of the Homeopathic Convention held at Atlantic City, that appeared in these columns some time since.

The matter has far wider significance and extent than pertain to any one medical journal or to any one publishing house, and at the slight risk of apparent egotism or Phariseeism it appears fitting to speak a few plain words of confession and resolution.

It has never been the policy of THE MEDICAL NEWS to allow itself to be prostituted to the book-publishing business. No rules, tacit or explicit, have ever been laid upon THE NEWS to limit or handicap its independence of judgment or action. Its sole aim is to serve the interest of its subscribers and to perform its duty to Medicine. The business of book-publishing is distinct, and is entirely capable of caring for itself without control, hidden or hinted, of editorial function. Any limitations of expression that would sacrifice conscience to finance and shape editorial judgment or utterance by conditions of fiscal cunning or prudence, would not be given or received. Wherefore, medical sectarianism and superstition, however powerful commercially, will find THE MEDICAL NEWS no subservient tool. It is the duty of the journalist of scientific medicine to expose quackery with merciless persistence. It is high time that medical periodicals were emancipated from slavery to medical charlatanism, and from commercialism, whether of the publisher, of the advertiser, or of the book-buyer. If the books of a publishing house have not merit to sell themselves let them remain unsold. If the buyer refuse to purchase a good book because of an irate prejudice, he has thereby devised a fortunate method of suicide—since ignorance is its own blessed reward and ends in its own undoing.

As regards books sent to this office for review, THE NEWS shows no partiality to any publisher, its own, or other. Such books are sent to conscientious and competent experts, and these are instructed to express their judgments utterly regardless of author or publisher. The anonymousness of the criticism is a further guarantee that impartiality and plain speech are encouraged.

We desire to be explicit and emphatic that the reading and editorial columns of THE NEWS cannot be used in any way whatsoever to further the interests of the publishers or owners of, or dealers in any books, instruments, proprietary medicines, foods, preparations, etc., etc. Commerce is one, medicine another and a different pursuit. The aim of the true physician must be to keep them distinct in so far as there exists the most remote tendency of the lower to dominate the higher calling. The manifold offices of the purveyors of the physician's armamentarium are noble if nobly filled, highly honorable, and upon them the physician is largely and gratefully dependent. But it may never be forgotten for an instant that the products of the book-publisher, the instrument-maker, and the pharmacist are tools, aids, and helpers, in the hands of a specially-trained intelligence. Shall the instrument dictate to the hand?

There died the other day an editor of a daily newspaper, who some years ago quietly refused the greatest material bribe probably ever directly offered to a man. It is good to know that in response to a self-imposed duty there has lived one that could

resist the offer of five millions of dollars in cash for the simplest and easiest of services—silence. It is, of course, ridiculous to compare little things with great, and yet one of the harassing and wearying things of every position of trust is the wariness and watchfulness one has constantly to keep up to avoid becoming the dupe of money-making schemers and of one's own selfishness. The bribe is so subtle, so indirect or so unblushingly direct, so easily accepted, the shirking of responsibility so small an affair!

Out of the whole there rises the clear and patent fact of the power and baneful influence of medical obscurantism. Our fathers have evaded their obvious duty and allowed the many-headed monster to grow until the folly and sin are appallingly evident, and, lo! it is found that the animal would—threaten! What means this perfectly sickening fact that in the grand old State of Massachusetts every form of besotted and delusional quackery is unrestricted by law and allowed to fatten itself on the ignorance and want and trustfulness of the poor, and of some of the more pitiable rich? Do what they will, the educated, the honorable and scientific leaders of medicine are unable to get any law passed limiting the practice of medicine to those showing the most rudimentary qualifications or fitness. Upon attempting it the horrid beast at once raises its hundred heads, and before its hissings and barkings the lawmaker's heart fails as he thinks of the next election.

And there, and everywhere, flourisheth—faith-cure (that never cures); Christian science (that is unchristian and unscientific — to emesis!); the laying on of hands (that are dirty); spiritism (without spirit); spiritualism (without spirituality); Hahnemannism (either with or without the itch, the high potencies, the succussions, the smelling of medicines, the divine *similia similibus* — either with or without, *comme vous-voulez!*); eclecticism (that chooses the follies); -pathies, -isms, and crankeries, that laugh at themselves, and lunacies galore!

Brethren, the longer the delay the more drastic the remedy. Compromise and shilly-shally will not avail. It is quite useless much longer to sing:

"O how
Shall we escape from this terrible cow?
We will sit on this stile
And continue to smile
And perhaps we shall soften the heart of this cow."

THE RULES AGAINST THE PUBLICATION IN MEDICAL JOURNALS OF PAPERS READ BEFORE SOCIETIES.

THEY should be rescinded! And for the following reasons:

1. Because in the present rapid advance of science, conclusions reached are often changed or modified by the author or by another investigator before the article is published in the regular Society Report. The Report is not delivered to the subscriber for several months or a year after the meeting has been held. Untrue science is not science. The official reports of the International Medical Congress held in August, 1890, have not yet been issued.

2. The weekly or monthly medical journal gives the article the desired publicity at once. Stale news is not news.

3. Because the medical journals have a larger circulation than the "Transactions" and Society Reports, and reach thousands of readers that would never see the complete article in the belated Society Report.

4. Because the best men will not consent to hide their best work in a Society Report when it can be given to a large audience at once through a medical journal. The result is that Society Reports are prone to become lumber-rooms of second or third-rate matter.

5. The manifest injustice of the by-law to authors, and its detrimental effect upon medical progress, to some extent at least excuses Society members for breaking a rule they either regret having thoughtlessly assented to, or that they more probably had no voice whatever in making. Those who rigidly observe the rule find their articles locked in the "lumber-room," while the papers of their colleagues are read by the great world that is determined to take and read the live medical journals of the present day.

6. If the public desires to know about an author's productions the medical newspaper will most certainly satisfy the demand. It is better that the author should speak directly to others than through the mediation of the stenographer. The author can give his own information more accurately than can the reporter. The rule forbidding a member to make his own abstracts for the medical press is outrageous. Every writer has a vital interest in being correctly reported.

7. The first law as to literary property is that an

author shall have the right to dispose of the products of his intellect as it pleases him. Personality should not be merged in the medical association. The Society is only one medium through which an original worker gives the world the products of his thought and experience. As in the outside world a lecturer reserves and preserves the right to print his lecture where he will, so Medical Societies are sufficiently rewarded by the spoken word and presence, without any claim to the manuscript.

8. The late-coming Society Report and "Transactions" are, as a rule, relics of by-gone days and "survivals" of out-lived habits. Before medical journalism attained its present development and perfection the Society Report was necessary, and satisfied the demand of its day. It does so no longer. The multiplication of first-class special medical journals gives the specialist the means of reaching those of his own guild throughout the world, and the large number of unexcelled serials devoted to general medical literature that every week and month supply the avid desire of myriads of widely scattered readers, are sufficient proofs that "the times have changed," and that "we must change with them."

A LITTLE FABLE.

ONCE upon a time there was a kind old lady that lived in a big country over the sea, and who raised a great many chickens. One fine morning the good old lady took her little grandson with her to see the chickens fed. The little boy thought it great fun, until they finally came upon an old hen that would not budge from her nest, but pecked at the grandmother most viciously. Then the old lady took her stick and drove the hen from the nest. Immediately the hen set up such a cackling, and screaming, and blustering of feathers, and flew at the grandmother so savagely, that the little boy was nearly frightened out of his wits. He had never heard such a noise! What a horrible thing it was, to be sure!

GRANDMA: Do not be frightened, my child, the hen is not dangerous. She has more feathers and noise than fight—hens do not bite, they only peck.

BOY: But what ails the hen, Grandma, and why does she make such an awful fuss?

GRANDMA: Nobody knows exactly what ails her, my boy; she is just an old settin' hen, that's all—I call her the old homeopathic hen.

BOY: What a name! What does "hommypatic" mean, Grandma?

GRANDMA: I am sure I don't know, and I guess nobody else knows. Perhaps it sounds like her cackling. A stranger one day said she was a homeopathic hen.

BOY: But, Grandma, there is only one egg in the nest. Do hens sit on one egg?

GRANDMA: Homeopathic hens do.[1] A great while ago this hen laid quite a number of eggs, and she sat on them a long time.

BOY: Did the eggs hatch out into chickens, Grandma?

GRANDMA: Not one of them, my boy. They were a sorry sort of eggs; according to the stranger-man, one was a "psora," or itch egg; another was marked "thirtieth dilution;" then there were "succussion" eggs; "high potency" eggs; "immateriality of disease" eggs; "smelling of medicine" eggs; and a lot more very, very curious eggs.

BOY: What fearful words, Grandma. What do they mean?

GRANDMA: Nobody could ever tell me.

BOY: What became of those eggs?

GRANDMA: After the old hen had sat on them for a long time, and they had begun to stink very bad, she herself kicked them out of the nest, and I had to hold my nose while I threw them away.

BOY: Why did they not hatch out, Grandma?

GRANDMA: They had no "tread" in them.

BOY: What is "tread," Grandma?

GRANDMA: It is a bit of fatherly kindness and help on the part of the rooster, that makes the egg capable of hatching out into a chicken, and thus becoming of some good in the world.

BOY: What is the rooster's name, Grandma?

GRANDMA: Some call him "Science," but a better name is "Common Sense."

BOY: The one egg still left in the nest, Grandma—what is that for?

GRANDMA: That is the nest-egg, and we leave that so the hen may lay more eggs.

BOY: Will the hommypatic hen lay more eggs, Grandma?

GRANDMA: No, my boy. I told you she was just an old settin' hen, and settin' hens don't lay eggs.

BOY: If she will lay no more eggs, why don't you take this one away?

GRANDMA: Alas! it is also rotten.

BOY: Has this nest-egg any name, Grandma?

GRANDMA: It is called the *similia* egg.

BOY: What does that mean, Grandma?

GRANDMA: It has absolutely no meaning, that I could ever learn. The stranger-gentleman didn't explain, and we cannot understand the language of

---

[1] "The only 'certa' in the Master's teachings are the fundamental rule for the selection of the remedy, *similia similibus*, etc." (R. E. Dudgeon, M.D., of London, Honorary President of the International Homeopathic Congress, on "Homeopathic Certa and Dubia," quoted by Helmuth as "the belief of the Convention." See *N. E. Medical Gazette*, Aug., p. 392.)

hens, and so do not comprehend their own explanations.

BOY: If you take the simmily egg away, will the hommypatic hen still keep on settin' on nothing?

GRANDMA: O, yes, of course.

BOY: What a foolish hen! * * * * * * * — If you should throw cold water on the hommypatic hen, Grandma, would she still keep on settin'?

GRANDMA: Ah, my child! she has had more cold water thrown on her than would drown twenty sensible hens, but she keeps right on. She gets very mad when you throw cold water on her, or poke her up; but if you don't do it, she would starve on her addled old egg. She likes to flatter herself she is a great martyr.

BOY: Why don't you kill her, Grandma?

Hæc fabula docet—much or little, according to who the reader is.

SOCIETY PROCEEDINGS.

SEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

Held in London, August 10 to 17, 1891.

(Continued from p. 279.)

PROFESSOR BROWN gave an exceedingly interesting demonstration of animal parasites, first treating the subject generally, and taking up the questions of symbiosis, mutualism, commensualism, and parasitism.

PROFESSOR RALLIET considered the subject of "Parasites Transmissible from Animals to Man." These parasites are vegetable or animal. The vegetable parasites included besides the bacteriaceæ or microbes and divers saprophytes that were only accidentally parasitic, the fungi (*tricophyta*) which caused the several affections designated by the name of "tinea." The animal parasites might be divided into external and internal parasites.

Of the internal parasites some were common to man and animals, or, living more especially in animals, might develop accidentally in man; they were often transmitted indirectly, while others must necessarily penetrate into the human organism in order to complete their evolution, and hence their transmission was always direct (*Tenia solium*, *Tenia saginata*).

Indirect transmission took place very generally through the medium of drink or food, polluted or infected by the deposition of ova or embryos.

Direct transmission was brought about by the consumption of the flesh of infected animals. In this case the parasites living in the larval state in animals attained their complete development in man (*Tenia solium*, *Tenia saginata*, *Bothriocephalus latus*, *Trichina spiralis*.)

Prophylaxis must be regulated by the indications furnished by the preceding data: 1. So far as concerned external parasites, man ought, as far as possible, to avoid contact with animals suffering from parasitic affections transmissible to his species; he ought to endeavor to destroy the parasites and their progeny, not only in those animals themselves, but also in all spots which might have been infected. 2. Since internal parasites were introduced generally through the medium of food or drink, it was expedient only to consume these substances after a careful examination and after having purified them, when necessary, by boiling, filtration, or other means. 3. Certain sanitary measures might contribute effectively to the completion of the protection.

In the Section of Infancy, Childhood, and School Life, DR. FRANCIS A. WARNER read a paper on "The Scientific Observation and Study of Children in Schools." The bearing of the paper was sociological rather than medical.

DR. JACOBI suggested that feeble-minded children should be trained apart from others, so as not to impede the progress of more intelligent children, nor to suffer from undue pressure by competition with the latter.

MR. NOBLE attributed a good deal of physical deformity among the children of the working classes to poor nutrition during childhood, in part resulting from ignorance and carelessness.

DR. OCTAVIUS STURGES read a paper on "The Early Recognition and Probable Arrest of St. Vitus's Dance in School Children." He had notes of forty cases of chorea admitted to the hospital in six months, and he had come to the conclusion that the exciting causes were chiefly examinations, puzzling over sums, and punishments. Children were frequently kept at school after the disease had commenced showing itself by restlessness, and thus entailing unmerited and injudicious punishment. Chorea often manifested itself also by the child becoming ill-tempered, restless, and untidy. The early want of nerve-control was first expressed in the hand, and was shown in bad writing and bad ciphering, which entailed punishment, until the child became really ill. Thus the disease had two distinct phases—the teacher's and the doctor's. The teacher punished unwittingly and ignorantly, and then the doctor stepped in. If he had been called in when the nerve symptoms commenced, proper treatment would have set the child right; but things were allowed to go on until the case became one for hospital treatment. St. Vitus's dance was first detected by observation of the muscles of the face, which twitched; then, if the child became ill-tempered and untidy in his appearance, inquiries should be made of the mother if the child slept well and had sufficient food. He said if there were any muscular infirmity the hand test was infallible. If the child could hold up both hands straight with the fingers open, and there was no falling back of the hands nor quivering of the muscles, he was free from any danger of chorea.

DR. CHEADLE stated that besides nervousness and the wear and tear of learning, excitement was also a cause of chorea. He thought chorea a grave disorder, often complicated with heart disease.

MR. MALCOLM MORRIS read a paper on "Ringworm in Elementary Schools." Both he and DR. T. COLCOTT FOX insisted upon isolation of children having the disease.

DR. SHELLY read a paper on "Epidemics in Schools," for the prevention of which he suggested a system of health certificates, quarantine, and disinfection.

In the Section of Chemistry and Physics in Relation to Hygiene, SIR HENRY ROSCOE delivered the Presidential Address. He dwelt upon the progress of the last

fifty years, upon the water-supplies of to-day as compared with those of the past, upon the disposal of excreta, upon the matter of air-pollution, and upon the chemical products of bacterial action.

DR. THEODORE WILLIAMS stated that fogs were well known to cause a large increase in mortality from certain chest affections and from anemia. Persons suffering from bronchitic asthma were, however, benefited by London fogs, and he had found that certain patients suffering from this disease improved in health rapidly when living in a London fog and when exposed to the air of the Metropolitan Railway.

MR. ERNEST HART said that he was sure that Dr. Williams did not mean to imply that the experience of a few persons subject to a disease so capricious as asthma had any general value for the decision of the question in hand. To create or tolerate London fogs for the sake of a few asthmatics would be to burn down the house for the sake of roasting the pig. The mortality of London during the previous great fogs had been as great as in a cholera season. Private houses were the main sources of smoke in towns such as London, and this affected not only the purity of air, but the amount of light. A few years ago roses would grow in London; they would not do so now. The bleaching of wax was carried on in London twenty or thirty years ago, but this industry could not be carried out there now.

DR. TRIPE emphasized the mortality due to fog and smoke.

DR. E. HAUGHTON advocated the compulsory use of closed grates and the imposition of a tax on open fireplaces.

PROFESSOR F. W. OLIVER referred to the injury to vegetation by town fogs. He exhibited a series of diagrams showing the injuries caused to the various organs of plants by fogs and by very dilute mixtures of sulphurous acid with air, the injuries caused by the latter method being identical with those observed with fogs.

DR. SHERIDAN DELÉPINE and MR. A. B. GOMESS exhibited an interesting and ingenious apparatus designed to show the "possibility of removing the smoke of fires from the air of towns and of using it for disinfecting sewers." By means of a small amount of water falling from a moderate height (a few feet) it was possible to produce a displacement of a large amount of air, and to divert the smoke of a fire from a chimney into a system of pipes running in any direction, and by a very simple combination of channels and chambers the sewage itself might be used for the purpose of displacing the smoke and causing it to mix with the sewage.

DR. SIMON read a paper on the "Organization of Local Boards of Health," which, he maintained, should be distinct from, though subject to, those of local self-government, and under the direction of a physician giving his whole time to the work. In towns with over 300,000 inhabitants there should be several such boards, identical in constitution, but under the direction of one central board and its chief. Each board should be divided into sections dealing respectively with (1) sewerage, water-supply, and public and private buildings; (2) food-supply and adulteration, with, if possible, a bacteriological station; (3) the notification and repression of infectious diseases, and the hygiene of dwellings and schools; and (4) vital and nosological statistics.

In the Section of Preventive Medicine, DR. EDWARD SEATON opened the discussion on "Diphtheria." He stated that while no climate afforded immunity, the tropics suffered less than cold and temperate climates. He expressed the opinion that diphtheria was uninfluenced by general sanitary conditions.

DR. SCHREVENS presented statistics of diphtheria in Belgium which showed that the mortality curve of diphtheria was similar to that of enteric fever, the largest number of deaths occurring from both diseases in the same districts. He believed that both diseases were fecal diseases.

MR. M. A. ADAMS discussed the "Relationship Between the Occurrence of Diphtheria and the Movement of the Subsoil Water." He believed that the organism of diphtheria inhabited organically polluted surface soil and was liable to displacement and to dispersal into the superincumbent air.

DR. GIBERT stated that since thorough disinfection had been carried out in Havre there had been a distinct decline in the mortality.

DR. JULES BERGERON presented statistics showing that for a number of years the progress of diphtheria in France had been uninterrupted.

DR. C. E. PAGET presented figures that pointed to a correspondence between diphtheria on the one hand and the general mortality rates and general sanitary circumstances on the other.

DR. C. N. HEWITT presented facts that seemed to prove that the disease was infectious, that it was communicable by persons and things, that the infection lived and grew outside the body and below its temperature, that it was tenacious of life as against measures of disinfection, and lived for long periods in clothing and bedding and on floors and walls. Isolation and systematic disinfection, with the most perfect sanitary regulation, were most efficient at present in the control of the disease.

In the discussion that followed, Professor D'ESPINE, DR. JANSSENS, and DR. ESCHERICH took part. The tendency of the discussion was to the effect that local disinfecting measures were effectual, or at least of great use in preventing the spread of diphtheria.

DR. THURSFIELD believed that the failure of sanitary improvements to stop the increase of diphtheria was to be attributed to the dissemination of the disease by very mild, medically unattended, and therefore not notified cases, generally acting through school agency. Further, more importance should be attached to the fact that the chief influence favoring the incidence of the disease was personal susceptibility.

DR. TRIPE stated that it was noticeable that good drainage had but little effect in diminishing the virulence and extent of epidemics of diphtheria. The best method of preventing the spread of an epidemic was the destruction by fire of all rags infected by secretions. He believed the affection was spread by contact, and he had found that closing the play-ground was as effectual as closing the school.

In the Section of Bacteriology, DR. ROUX opened the discussion on Immunity. He stated that recent advances in the subject of immunity had in common the attenuation of virus and preventive inoculation. Two methods of attenuation had been described by Pasteur: prolonged

exposure of a culture to air at a suitable temperature, and the passage of the organisms through the bodies of different species of animals. Other methods had also been employed: for example, the action of heat, the use of antiseptics, and of compressed oxygen and light.

In all cases, whatever the method employed, it was found to be necessary that the attenuation should be effected slowly and gradually; rapid attenuation rendered a virus altogether inactive without impressing on it any hereditary weakness. In whatever way the virus was prepared it must, in order to confer immunity, be brought into direct contact with the tissues of the animal. In the early experiments the virus employed was always living; the living microbe, itself attenuated as to its virulence, was used. Another possible method of conferring immunity was the inoculation of the chemical products produced by the microörganisms. Dr. Roux discussed the theory of phagocytosis and the nature of immunity.

DR. HANS BUCHNER stated that there were three conceptions of the causes or determining factors of an already existing immunity: (1) Want of nutritive material in the tissues and tissue juices, whereby the bacteria were destroyed. (2) Phagocytosis, that is, the capture of the generating factors of infection by the ameboid cells of the body, with subsequent destruction of them by chemical action inside the cells. (3) Prophylactic substances in the animal tissue juices.

MR. E. H. HANKIN stated that immunity depended upon the presence of certain bacteria-destroying substances, to which the name "defensive proteids" had been given. From what was known of defensive proteids, it appeared very unlikely that many chemical tests would be found capable of distinguishing them. Consequently they must be classified by their physiological characters. Defensive proteids may be either sozins—present in the normal animal, or phylaxins, present in artificially immune animals. Sozins are again subdivisible into myco-sozins, that destroy the microbes, and toxo-sozins, that destroy the microbic products. Phylaxins are subdivisible into myco-phylaxins, that destroy the microbes, and toxo-phylaxins that destroy the microbic products.

PROFESSOR EMMERICH stated that bactericides were probably intermediate products of decomposition, a stage in the passing of albumin into fat. Hence it was probable that the blood and tissues of immune animals, which contained matter energetically poisonous to bacteria, must, if injected subcutaneously, also act as a remedial agent in infectious maladies.

PROFESSOR ARLOING showed that the power of naturally immune animals to resist microbic poisons was due to a natural tolerance for the poison analogous to that met with in animals that had acquired tolerance after treatment with attenuated vaccines.

PROFESSOR EHRLICH reported some experiments with anti-toxines, and then discussed the question of inheritance. He stated that the descendants of highly immune fathers were not themselves immune, while, on the other hand, the descendants of immune mothers were relatively immune, but in a less degree than the parent.

PROFESSOR HUEPPE stated that the opinions on the part played by the cells and the blood serum were still very diverse. The cells, however, could afford to wait if justice was not being done to them, for they would come to the front again in due time. Experiments on the chemical properties and the trophic properties of cells had triumphantly established the primary cell phenomena that had already been discussed. In those phenomena it was necessary to distinguish between the effects produced by the products and those produced by the cell protoplasm itself.

DR. KITASATO stated that, in conjunction with Dr. Behring, he had shown that an injection of the blood of rabbits which had been made artificially immune from tetanus by means of trichloride of iodine rendered mice not only refractory to tetanus, but also cured the disease when it was already in progress. This proved that blood rendered artificially immune was really efficacious against a malady of so acute a character as tetanus.

MR. ADAMI stated that the bacteriological world was at the present moment divided into two opposed camps—those who held that microbes within the system were destroyed by the agency of the living cells, and those who held that the function of microbic destruction was performed by the blood serum and body fluids in general. He wished especially to emphasize the fact that there was ample evidence that the controversy upon the subject turned after all upon phenomena that differed not so much in kind as in degree. The controversy tended rather to be about words than actuality. An observer who studied the matter with an open mind could not fail to be struck by the prevalence of phagocytosis. It was quite possible to accept both views. The controversy had taken place chiefly as to the phenomena observed in the rat; in that animal phagocytosis was only to be observed with difficulty, and the serum of rat's blood undoubtedly possessed bacteria-killing properties to a high degree.

DR. KLEIN observed that ordinary frogs and rats were insusceptible to anthrax, but these animals had been made susceptible thereto by a variety of means, which seemed to indicate that there were certain chemical conditions at work. If virulent material were introduced into the lymph-sac of a chloroformed frog, the frog always died of anthrax. Several other instances of such effects were given, but there was nothing to see under the microscope that would justify anyone in saying that the blood corpuscles had lost anything of their power of swallowing up bacteria. The experiment showed that certain chemical changes had been established in the blood—it might be entirely independent of the leucocytes—which were sufficient to destroy the substances that were normally present in the blood of the frog or the blood of the rat, which counteracted the action of the anthrax bacteria.

DR. METSCHNIKOFF said that Behring and Kitasato had discovered the bactericidal power of the serum of guinea-pigs inoculated against the vibrio Metschnikovii. They had demonstrated that whereas this vibrio developed readily in the serum of guinea-pigs, which were susceptible to the malady after being in the body from three to five hours, it was destroyed in the body of the inoculated guinea-pig. The serum of the inoculated guinea-pig killed the vibrio in a very short time, whereas in the serum of a susceptible guinea-pig they developed in great numbers. Animals completely inoculated against infection were as susceptible to toxic doses of

sterilized cultures as animals not inoculated at all. The inoculated guinea-pigs died after the same dose as those not inoculated, and the inflammatory and febrile phenomena were the same. In the septicemia of guinea-pigs, of all the immunity factors known, the phagocytes had the most important action. The bactericidal power of the serum, remarkable though it was, did not confer immunity. The insufficiency of the theory founded on the microbicidal power of the body fluids had been admitted by Behring himself, and but few facts could be quoted in its support. Behring had himself acknowledged that this theory as to the bactericidal power of the blood could only be applied in diseases, such as tetanus and diphtheria, which were distinguished by their exceptionally toxic characters, and by the absence of diffusion of microbes. As was proved by Messrs. Vaillart and Vincent in regard to tetanus, the animals that were subject to this malady were already naturally refractory to the microbe. In this immunity from the microbe it was the phagocytes that played the principal part. If this theory were discussed fairly, and if Ehrlich's theory that the crisis in infectious diseases was really due to the rapid formation of the antitoxine, even then the part played by the phagocytes was still very important. Among the diseases in which a crisis occurred, relapsing and malarial fever might be cited. If the crisis were really caused by the destruction of the toxine in the organism, still if the microbe remained alive it could multiply, and cause a relapse more serious than the first attack. The spirilla of relapsing fever were destroyed by the phagocytes during the crisis and during the apyrexial period. In monkeys the spirilla were destroyed by the cell, and the illness terminated with the first attack; but in men the phagocytes were not generally able to completely destroy the spirilla, and a second attack occurred in spite of the formation of the hypothetical antitoxine. The same thing occurred in intermittent fever. In this all-important act of destruction of the microbes the phagocytes performed the most important part.

In the Section of the Relations of the Diseases of Animals to those of Man, DR. E. KLEIN considered "Infectious Udder Diseases of the Cow in Relation to Epidemic Diseases in the Human Subject." He contended that the infectiousness of milk was not due to contagion from a human source, but that probably a pathological condition of the milch-cows played a prominent part in giving to their milk the power of causing scarlet fever in the human subject.

PROFESSOR CROOKSHANK contended that there was no evidence in support of the theory that scarlatina or diphtheria in the human subject ever arose from eruptions or skin diseases of the cow.

DR. OSTERTAG expressed the opinion that scarlet fever was not communicable from man to animals. Dr. Löffler had inoculated animals with blood from the pustules of scarlet fever in man, but had never produced the disease in the cow. With regard to Dr. Klein's experiments, the general opinion in Germany was that Dr. Klein had confounded the disease in question with either cow-pox or foot-and-mouth disease.

PROFESSOR CHAUVEAU stated that, as the result of a very considerable number of experiments, he had found himself able in every case attempted to communicate the smallpox virus to bovine animals, but he had never in any attempt succeeded in transforming this smallpox virus into vaccine.

DR. DESHAYE read a paper on the "Hygiene of the Newborn Child." His conclusions were: 1. That in all cases in which the mother was able to nurse, the infant should derive its nourishment wholly and solely from the mother's breast. 2. Should the mother be unable to nurse her child, the child should be fed with cow's milk, sterilized. 3. The bottle (without a tube) should not be used before the morning after birth at the earliest. 4. The *frenum linguæ* should never be divided, unless it were so short as absolutely to prevent suction.

In the Section of Chemistry and Physics in Relation to Hygiene, DR. THRESH read a paper on the "Chemical Treatment of Sewage." He classified as follows the physical processes for the removal of specific organisms, of suspended impurities, of dissolved organic matters:

1. Subsidence—(*a*) with complete rest; (*b*) during slow, but continuous, flow.

2. Mechanical straining and filtration.

3. Chemical filtration, or percolation through materials exerting some chemical or catalytic action on the organic matters.

4. Precipitation by the addition of one or more chemicals. These may be (*a*) soluble, as the salts of iron and aluminium, or (*b*) insoluble, as clay, magnetic oxide of iron, and the various kinds of charcoal.

5. Electrolysis, or purification by electrical treatment.

6. Oxidation and destruction of the organic matter by addition of chemicals.

7. Sterilization and disinfection for the destruction of microörganisms and the arrest of putrefaction.

8. Nitrification, or the destruction of the organic matters by the action of the nitrifying organisms found in surface soils.

9. Irrigation, or the utilization of the organic matter as food for growing crops.

In exceptional cases only was one of these processes alone found to yield sufficiently satisfactory results, and two or more of them must be used in combination or in succession.

A resolution was passed "That, in the opinion of this meeting, the best yet known method of disposing of the sewage of towns is that of purification and utilization on the land."

In the Section of Naval and Military Hygiene, DR. SPOONER considered the subject of "Dietary Scales in Connection with the Health of Seamen." He criticized the ordinary dietary scales as containing too much salt meat and too little vegetables. On American ships, he said, potatoes were always given. He contended that, if a proper dietary scale were compulsory, scurvy would in a short time be entirely eradicated.

DR. HARRIS exhibited and explained "A Ship Ventilator," an apparatus constructed for the removal of air from cabins and confined spaces by means of an induced current without the admission of water. A long shaft was surmounted by a very large bell-mouth, narrowing rapidly at the base. Air entering and passing down the shaft was reflected upward and caused an induced current. If a sea washed in, the weight would open the valve and allow the water to run out. By the insertion of a valve the inlet might be converted into an outlet.

It was found by experiment that the ventilator was efficient to the extent of 20 per cent. of its theoretical work.

MR. HAMER read a paper on "The Homes of the Poor." The connection between insanitary dwellings, ill-health, and a low state of morals was, he maintained, even more close than that between ignorance and crime, and the pecuniary value of life and health was now so generally recognized that he hoped that these claims would not much longer be treated as secondary to the so-called rights of property.

DR. VON HAMEL ROOS urged the necessity of some international agreement as to what constituted adulteration, an article which was permitted in one country being liable to seizure when exported to another.

DR. DANFORD THOMAS treated of the "Sale of Poisons," whether as such or in the concealed form of proprietary medicines, and gave a sketch of the law on the subject in the chief countries of Europe.

CORRESPONDENCE.

MUNICH.

Prof. Sänger's Hysterectomy; Beer-drinking; Street-paving: Foreign Medical Students; Prof. Winckel and his Work; Operations; Winckel's Perineal Operation.

IN writing of the hysterectomy by Professor Sänger, I omitted two matters of some interest. One was that the operation was done with the patient in the Trendelenburg position, and the second was that the stump of the pedicle, after being thoroughly cauterized, Paquelin's thermocautery being used, was well covered with a mixture of equal parts of salicylic acid and tannin.

As one enters Munich he is impressed with the fact that it is a great center for the making of beer, for even if he does not recognize some of the many breweries, he will see on the side tracks freight cars bearing the names of many—I counted no fewer than eight. The Bavarian Government makes beer, and private individuals and corporations, so that there are probably between thirty and forty breweries in all, some of them immense establishments. I was told that while the export of beer is very great the quantity consumed in the city is by no means small, about one gallon daily for each adult. Of course, all adults do not take such an amount (I have no doubt some do), else there would be none left for children and visitors, and I am not aware that any total abstinence society exists among either, though really why beer, even Bavarian beer, is preferred to good water I do not know. It appears to be almost a part of religion to use beer in Munich! St. Anna has a brewery, St. Peter a beer hall, and I know not how many more saints have their names concerned in the making or the consuming of what may be specially called the Bavarian beverage.

While in Germany I have conversed with several medical men as to the use of beer in the Empire, asking them if the people would not be in better physical condition if they drank water instead of beer, and my question was always answered in the affirmative; there seemed also common agreement on the part of my informants that diseases of liver, heart, and kidneys were not uncommon in consequence of excessive beer-drinking.

Munich has not the excellent streets that Berlin or Leipzig has—boulders on some, some paved with granite blocks, most macadamized, but asphalt or wooden blocks are not found; fortunately it rains about four days out of five, it seems to me, and then the people are protected from dust, which would be very great, in consequence of the material most commonly used for streets. The city is said to be too poor to have better streets, but if a few of the many diamonds belonging to the State were sold, enough would be realized to make its great thoroughfares the envy of Berlin or Paris. The jewels are now utterly useless save for exhibition to visitors, and so carefully guarded that visitors are locked in the room during their inspection, with one or more soldiers present.

But though Munich is not well paved, she has the second largest medical school in the German Empire. Visiting this city now for the third time within three years, it still surprises me that comparatively few doctors and few medical students from our country come to Munich, while so many hundreds go to Vienna and Berlin. Munich's treasures of art—painting and sculpture more especially—draw thousands of visitors, hundreds of them from the United States, while for the sake of its medicine there is only an occasional visitor.

My coming has been solely for the purpose of seeing the work of my kind friend Professor Winckel, a man for whose ability I have the highest admiration, and for whom personally I entertain the highest regard. Dr. W. is the third in a generation of doctors—indeed, not only one but both of his grandfathers were doctors; his father, now more than eighty years of age, a few months ago did his nineteenth case of Cæsarean operation, and it was successful, though performed under most unfavorable circumstances. Professor Winckel is a man of almost encyclopedic knowledge in his department of obstetrics and diseases of women, but he also possesses great general literary culture—for example, in a recent number of a German review there is an article from his pen on "Sea Bathing as a Health-means," which is enriched by several historic and classic references.

It need hardly be told the readers of THE MEDICAL NEWS that for several years he has occupied the chair of Obstetrics and Diseases of Women in the Bavarian University, and that he has under his charge the Frauen-Klinik. Adjacent to the building of the Frauen-Klinik is his handsome residence, erected by the Government. He has had in the Klinik so far this year one thousand cases of labor, and a larger number of cases of diseases of women. Such a hospital at home would present an admirable opportunity for at least thirty or forty obstetricians and gynecologists, each confident of fitness and clamorous for place! It is a deplorable fact that in many of our public institutions professional places have been needlessly and injudiciously multiplied; honors and opportunities are there so diffused, a sort of common rain falling upon the just and the unjust, the fit and the unfit, that their value is depreciated, and the interests of neither medical education nor of patients promoted. During the teaching term Dr. Winckel works for six or eight hours every day, his operations beginning at 7 A.M., and continuing from one to two hours. In clinical instruction in diseases of women most American medical students have one hour a week, but the Bavarians have at least twelve hours each week. The practical instruction

in obstetrics given here is, of course, very thorough and complete, and I know no school in our country equal to it in these regards. The contrast between obstetric and gynecological teaching here and in the United States arises in part from the vastly greater abundance of material here at hand; but if our medical schools had money so as to have hospitals sufficiently large, and conducted not partially or principally, but solely, in the interests of the schools, then there would be a great advance, and the profession would rejoice, though a few place-hunters and time-servers would be ignominiously retired, muttering impotent maledictions. If I have spoken in this, or in other letters, of the defects, more especially in regard of practical instruction in obstetrics and diseases of women, of American medical education, it has been with deep sorrow, and yet with the assured hope that a better day will come, and trusting that some word of mine may have a part, even though very small, toward hastening that coming.

The lecture term is now over, and Dr. Winckel is usually absent upon his vacation travel, but this August he remains at home, because of an important obstetric engagement. In consequence of his usual absence at this time, comparatively few patients for operation are sent to the hospital by physicians. Nevertheless, during three days he has shown me fourteen operations, none without value, and some of them of great interest; two of the latter being abdominal sections, and one vaginal extirpation of the cancerous uterus. It is the rule in all the hospitals I have visited on the Continent, that the laparotomies are done in a room devoted exclusively to this work. Elsewhere, the use of antiseptics is strictly observed. The operator, his assistants, the nurses, and visitors, have white linen, double-breasted overcoats. Winckel and Martin alike operate sitting between the patient's lower limbs, and each uses Martin's table. The first abdominal section was done for osteo-malacia—consisting in a removal of the uterine appendages, or as they call it here, castration. The poor woman had been delivered of a living child six weeks before, by a midwife, who in the delivery performing podalic version, had fractured her thigh. Dr. Winckel has performed this operation on two other osteo-malacic patients, and the result was satisfactory in each case—indeed, one of the women, operated on two years and a half ago, is employed in the hospital, and I had an opportunity of examining her condition. In the castration I saw done the abdominal incision was quite short enough to please Mr. Tait or his followers, and the removal of the appendages quickly done. The pedicles were tied with silkworm-gut. By the way, one learns in Berlin the powers and utilities of catgut, in Leipzig of silk, and here of the *fil de Florence;* thus often doctors differ, each seeking the same end, but not employing the same means.

The second abdominal operation was done for the removal of a cystic ovarian tumor, but presented special difficulty from adhesions, more particularly to the posterior wall of the uterus, and these were divided chiefly by the thermo-cautery. The abdominal wound in the first patient was closed by three sets of sutures: continuous catgut for the peritoneum, then buried silkworm-gut for the muscular layer, and finally the same material for the skin. He is very careful to stitch with catgut the peritoneal margin of the stump together, thus preventing the possibility of subsequent troublesome adhesions.

Among the *Stuhl* operations were Sänger's modification of Emmet's operation for lacerated cervix, amputation of the vaginal cervix, the removal of a dermoid cyst from the right wall of the urethra—certainly a very singular case—colporrhaphies, and, as previously mentioned, vaginal extirpation of the uterus. In the latter, as in similar operations I have seen at Berlin last year and also this, clamps were not used, but ligatures—in Berlin of catgut, here of silkworm-gut chiefly. Martin cuts and ties, cuts and ties, and thus makes continuous extraction of the uterus; but Winckel, after opening the posterior and anterior cul-de-sac, inteverts the uterus, then ligates in parts the broad ligament of one side, divides it, after which that of the other side is similarly treated; he closes very carefully the vaginal vault with silkworm-gut.

The employment of the uterine sound is very common by Winckel, Martin, and others of the great operators whom I have seen in Germany, and the condemnation of this instrument in some quarters arises, it seems to me, from partial experience or from puerile judgment, or from its employment without proper precautions. How weary one becomes of the positive assertion and defiant dogmatism arising from partial knowledge and limited personal experience!

One of the reasons for my great admiration for Dr. Winckel is, that while he does not hesitate at the gravest operations when satisfied they are necessary, he is eminently conservative. For example, a patient with myoma of the uterus, the organ reaching as high as the umbilicus, or above, was sent to the hospital because of obstinate metrorrhagia. On the part of some the case would invite immediate hysterectomy, indeed they might regard it as imperative, while others would think that the uterine appendages ought to be removed. Dr. Winckel was unwilling to do either until he had tried less heroic means; he dilated, using Schröder's dilators, curetted the cervical canal, and applied muriated tincture of iron—looking to castration next, should this fail, and placing hysterectomy last.

Very interesting to me was Dr. Winckel's perineal operation, and with a brief description of this my letter ends. This operation, like Tait's, Simpson's, and Sänger's, is a flap operation; and, like those of the two former, is performed without removing any tissue. The patient is placed in the usual position for such operations, two assistants holding the lower limbs, and the feet wrapped in towels that have been wrung out of a three per cent. carbolic acid solution; the pudendum is well washed with soap and water, at least the lower half shaved, an antiseptic wash, and then a three per cent. carbolic acid solution used with the irrigator to thoroughly cleanse the vagina. The operator then takes a double tenaculum with broad flat handle—Ziegenspeck's, I think it is, and the best instrument of the kind I have seen—and catches the tissues in the median line of the posterior wall of the vagina at a point as high up as the separation of the flaps, and gives it in charge of one of the assistants; a similar instrument in the skin just at the anterior boundary of the perineum; two similar tenacula are now used, one on either side just at the junc-

tion of skin and mucous membrane, where the external lateral separation of flaps is to be — the four tenacula being held by assistants. The operator begins the formation of the flaps by a semicircular incision with a scalpel at the vulvar orifice, within the three points held by the externally-placed tenacula, and it is then continued and completed by a rapid dissection until the level of the internal tenaculum is reached posteriorly. When the vaginal flap is drawn upward by tenaculum or forceps inserted in its border and in the median line, a trapezoid surface is then formed, which might be compared to that of an unfringed shawl opened and held by its our corners, or by imagining two triangles applied to each other base to base. But to make the meaning plainer, let me attempt an illustrative diagram. In Fig.

FIG. 1.

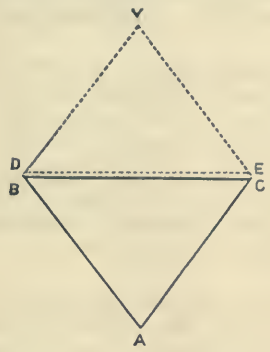

FIG. 2.

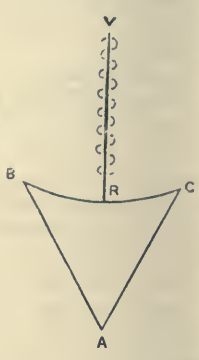

1 the vaginal triangle, *VDE*, is represented by dots, the rectal, *ABC*, by lines—*V* is the limit above of the flap, *DE* is its base and marks the end of the separation of the flaps; *A* is the termination at the anus. These triangles are to be closed. This has its first step in stitching together *VD* and *VE*, the catgut suture being used for this purpose, and it is begun at *V*. It should be remembered that this flap has never been separated at the sides of the vagina, and hence the stitching brings together surfaces that have heretofore been attached to the surface *ABC*, and also narrows the vagina, especially as the stitches approach and include the base of the triangle. As the stitches descend toward the base of the dotted triangle, and especially when near completing the stitching, obviously the line *BC* becomes shorter, and the form of the second triangle is changed with the disappearance of the first; possibly, the presentation of an illustration (Fig. 2) may make the matter clearer. *VR* represents the closure or obliteration of the upper triangle, and *ABC* the lower, changed somewhat in form. If *ABC* were a plain surface the operation would be immediately completed by the introduction of four to six perineal sutures; it is not, however, such a surface, but presents quite a sulcus in the median line *RA*, and, therefore, a series of silkworm-gut sutures, four or five, are introduced so as to include the middle third, or rather more, of this surface, and the ends cut off quite short; thus the sulcus is caused to disappear, and the triangular space much narrowed. The operation is ended with the introduction of the external sutures and tying them, after which the two ends of each are knotted together about two inches from the skin and the free portion cut off; the utility of this knot is obvious.

If any reader should find fault with the details into which I have entered, condemning them as too elementary, I will not repeat the words found in an old herbal under a certain plant, *Apage! Non tibi spiro*, but apologize by saying that I write hoping to teach some who have been as ignorant as I was in regard to the method of performing what seems to me an admirable operation for partial rupture of the perineum, with its frequent consequence, prolapse of the posterior vaginal wall.

T. P.

NEWS ITEMS.

As to Railway Fares, etc., of those Attending the Congress at Washington.—The Trunk Lines, the New York and Boston lines, the Southern Passenger Association, and the Central Traffic Association, will transport persons wishing to attend the Congress from points on their lines to Washington and return at the price of one and one-third the regular fare on the following conditions: The going ticket must be purchased within three days before the opening date of the meeting. Each person availing himself of the concession must pay full first-class fare going to the meeting, and must obtain a certificate from the agent of whom the ticket is purchased. Those holding such certificates, when countersigned by the proper officer at the Congress, can obtain return tickets at one-third the highest limited fare.

Certificates are not transferable, and the return tickets secured upon certificates are not transferable. If any of them are sold or transferred they must be redeemed at the highest first-class rate by the person making such sale or transfer. No certificates will be countersigned at the Congress except those presented by physicians attending the Congress, or their wives and members of their families; nor will any certificate be countersigned after September 26th. No refund of fare will be made on account of any person failing to obtain a certificate. Those who wish to avail themselves of this method of obtaining reduction in fares, should present themselves at the office for certificates and tickets at least thirty minutes before departure of trains. It is absolutely necessary for each passenger before starting to obtain a certificate from the ticket agent of whom the going ticket is purchased, otherwise he can obtain no reduction in the return fare. There will be no stop-over privileges on the return tickets, which must always be by the same route as the going ticket. Members may obtain tickets on these conditions for their wives and members of their families, as well as themselves. Tickets for the return journey will be furnished only provided the *properly countersigned certificates* are presented to agent at return starting-point within three days after the adjournment of the Congress, Sunday not to be counted as a day.

The Congress of American Physicians and Surgeons.—The Congress meets in Washington, D. C., September 22d to 25th, inclusive. It is composed of the members of those national medical societies whose names and secretaries are given below, and of foreign guests specially invited by the Executive Committee. To enable a physician residing in the United States to become a member of the Congress, with the right to participate in its pro-

ceedings, it is necessary that he be a member of one of these constituent national societies. A physician may be accredited as a visitor to the Congress by any one of the constituent societies. The certificate of the Secretary of one of these societies to the effect that he is thus accredited, will enable him to register upon payment of the registration fee, which registration will entitle him to a card of admission to the President's reception and to a copy of the *Transactions* of the Congress, but not to take part in the deliberations of the Congress.

The following are the names of the constituent societies in the order of date of their organization, and the names and addresses of their respective secretaries, to whom inquiries as to mode of obtaining membership should be addressed:

American Ophthalmological Society; Secretary, S. B. St. John, M.D., Hartford, Conn. American Otological Society; Secretary, J. J. B. Vermyne, M.D., New Bedford, Mass. American Neurological Association; Secretary, Graeme M. Hammond, M.D., 58 W. 46th St., New York City. American Gynecological Society; Secretary, H. C. Coe, M.D., 27 E. 64th St., New York City. American Dermatological Association; Secretary, Geo. Thomas Jackson, M.D., 14 E. 31st St., New York City. American Laryngological Association; Secretary, Charles H. Knight, M.D., 20 W. 31st St., New York City. American Surgical Association; Secretary, J. R. Weist, M.D., 118 N. 8th St., Richmond, Ind. American Climatological Society; Secretary, J. B. Walker, M.D., 1617 Green St., Philadelphia, Pa. Association of American Physicians; Secretary, Henry Hun, M.D., 33 Elk St., Albany, N. Y. American Association of Andrology and Syphilology; Secretary, J. A. Fordyce, M.D., 66 Park Avenue, New York City. American Orthopedic Association; Secretary, John Ridlon, M.D., 337 W. 57th St., New York City. American Physiological Society; Secretary, H. Newell Martin, M.D., Baltimore, Md. Association of American Anatomists; Secretary, D. S. Lamb, M.D., 800 10th St., Washington, D. C. American Pediatric Society; Secretary, W. D. Booker, M.D., 851 Park Avenue, Baltimore, Md.

All physicians are invited to attend the meetings of the Congress and the public meetings of the societies, but only those may register who are members, specially-invited guests, or visitors accredited through the secretaries of constituent societies. The registration office will be in parlors 1 and 2 of the Arlington Hotel. From this office the mail of members and invited guests will be distributed, and here the city address of each member, guest, and accredited visitor can be ascertained. All members, invited guests, and accredited visitors should register as soon as possible. A registration fee of five dollars will be required of all members and accredited visitors. Invited foreign guests will register, but will pay no registration fee. A copy of the published *Transactions* of the Congress will be sent to all members, and to each invited guest and accredited visitor who is registered. Only those who register, and the ladies accompanying them, will be admitted to the reception of the President of the Congress. It is recommended that members effect registration in advance of the meeting by filling out the blank certificates of registration which will be sent to each member about September 10th, and forwarding these certificates, with the requisite fee, to Dr. John S. Billings, Treasurer of the Congress.

The sessions of the Congress will be held from 3 to 6 P.M., daily, in the main hall of the Grand Army Building, 1412 and 1414 Pennsylvania Avenue. The sessions of the societies will be held according to the programs of each, as follows:

American Ophthalmological Society, Ladies' Parlor, No. 2, Arlington Hotel.

American Otological Society, Ladies Parlor, No. 1, Arlington Hotel.

American Neurological Association, Parlors 182 and 183, Arlington Hotel.

American Gynecological Society, Lecture Hall, Columbian University, cor. 15th and H Streets, N. W.

American Dermatological Association, Parlor, The Shoreham.

American Laryngological Association, Parlor A, Arlington Hotel.

American Surgical Association, Main Hall, Grand Army Building, 1412 and 1414 Pennsylvania Ave.

American Climatological Association, Hall No. 2, Grand Army Building, 1412 and 1414 Pennsylvania Avenue.

Association of American Physicians, Hall No. 1, Grand Army Building, 1412 and 1414 Pennsylvania Avenue.

American Association of Andrology and Syphilology, The Shoreham.

American Orthopedic Association, New Reception Room, Arlington Hotel.

American Physiological Society, Parlor 181, Arlington Hotel.

Association of American Anatomists, Hall No. 3, Grand Army Building, 1412 and 1414 Pennsylvania Ave.

American Pediatric Society, Parlor 206, Arlington Hotel.

The President of the Congress, Dr. S. Weir Mitchell, of Philadelphia, will deliver an address Wednesday evening, September 23d, at 8 P.M., "On the History of Instrumental Precision in Medicine." Members of the American Surgical Association and of the Association of American Physicians will conjointly entertain their foreign guests at a dinner at the Arlington Hotel, Thursday, September 24th, at 8 P.M. The American Gynecological Society will give a dinner at the Arlington Hotel, Thursday evening, September 24th. The American Orthopedic Association will give a dinner at the Hotel Arno, Thursday evening, September 24th. The American Laryngological Association will give a dinner at the Hotel Arno, Thursday, September 24th, at 7 P.M. The American Pediatric Society will give a dinner at the Arlington Hotel, Thursday evening, September 24th. The American Dermatological Association and the American Association of Andrology and Syphilology will, conjointly, give a dinner Tuesday evening, September 22d. The American Neurological Association will give a dinner at the Hotel Arno, Thursday evening, September 24th. The American Climatological Association will give a dinner, the time and place to be announced hereafter.

A number of distinguished physicians and surgeons from abroad have accepted the invitation to attend, among whom may be named Mr. B. E. Brodhurst, Mr. Thomas Bryant, Mr. A. E. Durham, Mr. Reginald Harrison, Sir William MacCormac, Mr. Howard Marsh, Dr. William M. Ord, Mr. Frederick Treves, and Mr. U. Pritchard, of London; Mr. Robert Jones, of Liverpool; Dr. W. T. Gairdner, of Glasgow; Mr. E. H. Bennett and Professor J. J. Cunningham, of Dublin; Professor

John Chiene and Dr. J. Battey Tuke, of Edinburgh; Mr. G. A. Wight, of Manchester; Dr. F. Beely and Professor H. Krause, of Berlin; Professor Curschmann, of Leipzig; Professor Hoffa, of Wuerzburg; M. Emil Javal, Dr. Loewenberg, Dr. Pozzi, and M. Paul Redard, of Paris; Dr. Von Mozengeil, of Bonn; and Dr. Rafael Lavista, of Mexico.

As other societies will meet in this city during the Congress week, it will be prudent for members and visitors to secure hotel accommodations in advance. The Arlington Hotel offers accommodations at the rate of four dollars per day, and the Hotel Arno at three and four dollars a day on the American plan, or one dollar a day per room only, on the European plan. The Committee will take pleasure in answering any inquiry relating to the local arrangements of the Congress.

Officers of the Congress.

President: S. Weir Mitchell, M.D.
Vice-Presidents, ex-officio: Presidents of Constituent Societies.
Chairman of Executive Committee: William Pepper, M.D., Philadelphia, Pa.
Treasurer: John S. Billings, M.D., Washington, D. C.
Secretary: William H. Carmalt, M.D., New Haven, Conn.

Committee of Arrangements.

Dr. Samuel C. Busey, *Chairman*, 1545 I Street, N.W., Washington, D. C.
Dr. John S. Billings, Army Medical Museum, Washington, D. C.
Dr. W. W. Johnston, 1603 K Street, Washington, D. C.
Dr. R. T. Edes, 1214 18th Street, Washington, D. C.
Dr. S. O. Richey, 732 17th Street, Washington, D. C.
Dr. J. Taber Johnson, 1728 K Street, Washington, D. C.
Dr. Samuel S. Adams, 1632 K Street, Washington, D. C.
Dr. I. E. Atkinson, 605 Cathedral Street, Baltimore, Md.
Dr. C. F. Bevan, 807 Cathedral Street, Baltimore, Md.
Dr. Samuel Johnson, 204 Monument Street, Baltimore, Md.
Dr. Samuel Theobald, 304 Monument Street, Baltimore, Md.
Dr. H. Newell Martin, Johns Hopkins Hospital, Baltimore, Md.
Dr. De Forest Willard, 1818 Chestnut Street, Phila., Pa.
Dr. D. S. Lamb, 800 10th Street, Washington, D. C.

The American Electro-therapeutic Association will hold its first annual meeting in the hall of the College of Physicians in this city, September 24, 25, and 26, 1891. The following program has been arranged:

First day, September 24th. President's Address, by Dr. G. Betton Massey, of Philadelphia.

Electro-therapeutics in America; an Historical Survey, by Dr. A. D. Rockwell, of New York.

The Action and Application of the Faradic Current in Gynecology, by Dr. Augustin H. Goelet, of New York.

Alternative Currents, by Dr. Horatio R. Bigelow, of Philadelphia.

The Treatment of Corneal Opacities by Galvanism, by Dr. L. A. W. Alleman, of Brooklyn, N. Y.

Second day, September 25th. Report of Seventy-five Cases of Uterine Myomata Treated by Electricity, by Dr. J. H. Kellogg, of Battle Creek, Mich.

Two Cases of Fibroids where Electricity Ceased to Control Hemorrhage after a Time, Although Eminently Satisfactory at First, by Dr. H. E. Hayd, of Buffalo, N. Y.

The Treatment of Fibroids by Electricity, by Dr. W. H. Hutchinson, of Providence, R. I.

Electro-puncture in Uterine Fibroids, by Dr. G. Betton Massey, of Philadelphia.

Electricity in Chronic Parametritis, by Dr. von Raitz, of New York.

Report of a Case, by Dr. A. H. Buckmaster, of Brooklyn.

Some New Applications of Electro-therapeutics, by Dr. Frederick Peterson, of New York.

The Analgesic Effects of Galvanism, by Dr. Landon Carter Gray, of New York.

Electricity in Diseases of the Stomach, with Exhibition of Patient, by Dr. Lawrence Wolff, of Philadelphia.

Electricity in Carcinoma, by Dr. Robert Newman, of New York.

(Title not received) by Dr. W. J. Morton, of New York.

(Title not received) by Dr. Henry McClure, of Cromer, England.

Some Points in the Technique of Electrolytic Epilation, by Dr. Plym S. Hayes, of Chicago, Ill.

Third day, September 26th. A Rare Case of Twin Extra-uterine and Intra-uterine Pregnancy Treated by Electricity, by Dr. G. H. Whitcomb, of Greenwich, N. Y.

Electricity in the Treatment of Rheumatism, by Dr. W. F. Robinson, of Albany, N. Y.

The Treatment of Subacute Articular Rheumatism by Electricity, by Dr. M. A. Cleaves, of New York.

Electricity in Ankylosis, by Dr. von Raitz, of New York.

Has Electricity any Action as a Germicide, or in Producing Poisonous Results in Food, by Dr. W. R. D. Blackwood, of Philadelphia.

Exhibition of a Rectal Electrode, with Remarks on its Application, by Dr. Guy Hinsdale, of Philadelphia.

Abdominal Electro-puncture in an Ovarian Tumor, by Dr. G. Betton Massey, of Philadelphia.

Eight Months' Work in the Dispensary for the Treatment of the Diseases of Women by Electricity, by Dr. H. R. Bigelow, of Philadelphia.

The American Climatological Association.—The eighth annual meeting of the American Climatological Association will be held on September 22d, 23d, 24th, and 25th, conjointly with the second Congress of American Physicians and Surgeons, in Hall No. 2, Grand Army Building, 1412 Pennsylvania Avenue, Washington, D. C.

The program is as follows:

TUESDAY, SEPTEMBER 22D, 10 A.M.

The President's Address, by Dr. Frederick I. Knight, Boston.

The Medical Treatment of Pleuritic Effusions, by Dr. George M. Garland, of Boston.

The Surgical Treatment of Acute and Chronic Empyema, by Dr. Maurice H. Richardson, of Boston.

The Drainage of Pulmonary Cavities, by Dr. Charles Denison, of Denver.

Notes on General *vs.* Local Treatment of Catarrhal Inflammations of the Upper Air-tract, by Dr. Beverley Robinson, of New York.

Gymnastic Exercise as a Prophylactic and Remedy in Chest Diseases, by Dr. E. O. Otis, of Boston.

The Effect of Change of Posture on Heart Murmurs, by Dr. Vincent Y. Bowditch, of Boston.

Nervo-vascular Disturbances in the Unacclimated in Colorado, by Dr. J. T. Eskridge, of Denver.

Whooping-cough and Its Management; Difficulties of Climatic Treatment, by Dr. John H. Musser, of Philadelphia.

Session of the Congress, 3 P.M.

Conditions Underlying the Infection of Wounds. *Referee*, Dr. William H. Welch, of Baltimore; *Co-referee*, Dr. Roswell Park, of Buffalo.

WEDNESDAY, SEPTEMBER 23D, 10 A.M.

A Study of the Sputum in Pulmonary Consumption, by Dr. E. L. Shurly, of Detroit.

Further Considerations of the Analysis of Recorded Cases of Phthisis Pulmonalis, by Dr. S. A. Fisk, of Denver.

The Histological Changes which Take Place in the Lungs in Cured Phthisis and the Influence of Diatheses in the Development of Such Changes, by Dr. Alfred L. Loomis, of New York.

Lymphatism, by Dr. F. H. Bosworth, of New York.

The Use of Creasote in Pulmonary Disease, by Dr. W. C. Glasgow, of St. Louis.

The Limitations of Bacteriological Therapeutics, with Especial Reference to Tuberculosis of the Lungs, by Dr. E. P. Hurd, of Newburyport.

Attempts to Discover Specifics for Phthisis, by Dr. H. F. Williams, of Brooklyn.

The Value of Koch's Remedy Employed as an Alterative: Reactive Fever Prevented, by Dr. Frank Fremont Smith, of St. Augustine.

Treatment of Sixty Cases with Tuberculin, at Davos, by Dr. Carl Kuedi, of Denver.

THURSDAY, SEPTEMBER 24TH, 10 A.M.

The Epidemiology of *La Grippe*, by Drs. E. W. Watson and R. G. Curtin, of Philadelphia.

Reports on the Late Epidemic of *La Grippe*, by Dr. John C. Munro, of Boston; Dr. A. Alexander Smith, of New York; Drs. R. G. Curtin and E. W. Watson, of Philadelphia; Dr. R. J. Nunn, of Savannah; Dr. E. Fletcher Ingals, of Chicago; Dr. Henry B. Baker, of Lansing; Dr. J. C. Mulhall, of St. Louis; and Dr. Charles Denison, of Denver.

FRIDAY, SEPTEMBER 25TH, 10 A.M.

An Experience with Diphtheria at a High Altitude, by Dr. W. A. Jayne, of Georgetown, Col.

The Waters of Richfield Springs, by Dr. C. C. Ransom, of Richfield Springs.

The Simultaneous Occurrence of Three Cases of Lepra in One Family: a Contribution to the History of Leprosy on the Eastern Coast of the United States, by Dr. W. H. Geddings, of Aiken, S. C.

The Pre-tubercular Condition, by Dr. J. H. Tyndale, of New York.

Early Diagnosis and Treatment of Phthisis, by Dr. R. C. M. Page, of New York.

The Etiological and Therapeutic Relations of the Different Forms of Tubercular Disease to the Climate of High Altitudes, by Dr. H. B. Moore, of Colorado Springs.

The Effect of Climate in the Treatment of Chronic Diarrhea, by Dr. W. W. Johnston, of Washington.

The Climate of the Hawaiian Islands, by Dr. Titus Munson Coan, of New York.

Notes on Laryngical Phthisis in Colorado, by Dr. H. M. Wilson, Jr., of Denver.

American Association of Andrology and Syphilology.—The fifth annual meeting of the American Association of Andrology and Syphilology will be held at the Shoreham Hotel, Washington, D. C., September 22, 23, 24 and 25, 1891.

The program of the meetings is as follows:

First day, September 22d. A Review of the Evidence of the Transmission of Syphilis to the Third Generation, by Dr. Abner Post, of Boston.

Relation of Syphilis to Stricture of the Rectum, by Dr. Robert W. Taylor, of New York.

Observations upon the Syphilitic Cachexia, by Dr. J. Blake White, of New York.

Abortive Treatment of Syphilis, by Dr. J. William White, of Philadelphia.

On the Occurrence of Nephritis in Syphilis, by Dr. John A. Fordyce, of New York.

Exhibition of New Instruments, by Dr. W. K. Otis, of New York.

Second day, September 23d. Some Experience with Supra-pubic and Perineal Drainage, Temporary and Permanent, in Vesical Disease, by Dr. Edward L. Keyes, of New York.

A Contribution to the Surgical Treatment of Ruptures of the Bladder, by Dr. Arthur T. Cabot, of Boston.

On the Use of Salicylic Acid in the Treatment of Certain Forms of Cystitis, by Dr. John P. Bryson, of St. Louis.

Undetected Stone, by Dr. William H. Hingston, of Montreal.

Spontaneous Fracture of Stone in the Bladder, by Dr. Francis S. Watson, of Boston.

Note upon a Possible Service to be Expected from Diuretin in Genito-urinary Surgery, by Dr. Edward L. Keyes, of New York.

Encysted Stone, Complicated with Growths of the Bladder, by Dr. C. H. Mastin, of Mobile.

Treatment of Vesical Calculus in Male Children, by Dr. J. William White, of Philadelphia.

Third day, September 24th. Further Report of a Case of Tubercular Cystitis, by Dr. L. Bolton Bangs, of New York.

Hematuria, by Dr. W. K. Otis, of New York.

Clinical Notes on (*a*) Hypertrophy of the Prostatic Sphincter; (*b*) Relation of Rectal Distention to Arterial Depression, by Dr. William T. Belfield, of Chicago.

Notes on the Surgery of the Prostate, by Dr. William N. Wishard, of Indianapolis.

Stricture of the Ureters, by Dr. Francis S. Watson, of Boston.

Observations upon the Surgery of the Ureter, by Dr. Arthur T. Cabot, of Boston.

Exhibition of Complete Double Ureters of Both Kidneys, by Dr. Edmund E. King, of Toronto.

Fourth day, September 25th. On the Radical Cure of

Urethral Stricture by Restoration of the Mucous Membrane to a Healthy Condition, by Dr. John P. Bryson, of St. Louis.

An Obscure Case of Chronic Non-specific Urethritis of Sixteen Years' Standing, by Dr. George E. Brewer, of New York.

The Treatment of Urethral Stricture and its Resulting Conditions by Excessive Local Distention and Without Cutting; Including a Brief Report of Fifty Cases, by Dr. James P. Tuttle, of New York.

New Methods for the Treatment of Urethral Disease Effected by the Use of the Speculum, by Dr. F. Tilden Brown, of New York.

Treatment of Gonorrhea, by Dr. W. Frank Glenn, of Nashville.

The Dry Poultice in the Treatment of Epididymitis, by Dr. George E. Brewer, of New York.

Exhibition of an Antiseptic Syringe for Hypodermatic Medication, by Dr. J. Blake White, of New York.

State Board of Medical Examiners of New Jersey.—The officers of the State Board of Medical Examiners of New Jersey for the ensuing year, selected at the first annual meeting held in Trenton, September 1, 1891, are: Dr. William L. Newell, of Millville, President; Dr. William Perry Watson, of Jersey City, Secretary; Dr. A. H. Worthington, of Trenton, Treasurer.

The Wuhu (China) Hospital, through the Physician-in-charge, George A. Stuart, has published its first report, covering a period of fifteen months. Work was begun in 1887, without buildings and without supplies. In 1889 a hospital was built. Twenty-six hundred and seventy new out-patients were seen, who made 8020 visits. There were 436 in-patients. Seventeen visits were also made to patients at their homes. A course of instruction in medicine was attended by three of the natives, and was in part successful.

The Apothecary is the name of a new quarterly journal, published by the Illinois College of Pharmacy, to be "devoted to pharmacy, chemistry, botany, materia medica, metrology, and to pharmaceutical education and progress." The first number is dated August, 1891, and contains original articles, editorials, and miscellaneous matters pertaining to pharmacy and cognate subjects. The appearance and arrangement of the journal is most creditable, its avowed objects commendable.

Inter-Continental American Medical Congress.—At a special meeting of the Susquehanna County (Pa.) Medical Society, held August 4, 1891, Dr. W. L. Richardson, of Montrose, Pa., member of the Auxiliary Committee of the Congress for Susquehanna County, introduced resolutions approving of the Congress, and pledging his society to do all in its power to promote interest in the meeting. The resolutions were unanimously adopted.

The Climatologist is the name of a new monthly journal of medicine, devoted to the relation of climate, mineral springs, diet, preventive medicine, race, occupation, life insurance and sanitary science to disease, to be edited by Dr. John M. Keating, Dr. Frederick A. Packard, and Dr. Charles F. Gardiner, and a list of thirty-one associate editors. The object of the *Climatologist*, as stated in its introductory, will be to promote original investigation and to record observations and experience on matters pertaining to the subjects indicated.

Professor Kocher, of Berne, on the 18th of July, celebrated the twenty-fifth anniversary of his appointment as docent.

Ricord.—The Municipal Council of Paris has appropriated 500 francs ($100) as a subscription to the memorial of Ricord.

Mount Carmel Hospital.—The corner-stone of an addition to the Mount Carmel Hospital, at Columbus, Ohio, was recently laid, with appropriate ceremonies. When completed, the building will have a frontage of 201 feet and a depth of 80 feet. There will be 70 rooms, three large wards, and an amphitheater on the fourth floor, with a seating capacity of 300. The interior arrangements are perfect and furnished with every facility for carrying on the work of the institution.

Angina Pectoris—Vincent Prize.—The Société Médicale des Hôpitaux offers the Auguste Vincent prize of 1000 francs ($200) for the best essay upon Angina Pectoris as Symptomatic of an Organic Affection of the Heart and of Arterio-sclerosis. Essays, in competition, should be in the hands of the secretary before the first of November, 1891.

The Tri-State Medical Association will hold its third annual meeting at Chattanooga, Tenn., October 27, 1891, and continue in session three days. The meeting promises to be one of the most largely attended medical meetings ever held in the Southern States. Representative physicians from all sections of the country will be present.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 1 TO SEPTEMBER 7, 1891.

CRAMPTON, L. W., *Captain and Assistant Surgeon.*—Granted leave of absence for fifteen days.

HORTON, SAMUEL M., *Major and Surgeon.*—Relieved from further duty at Fort Adams, R. I., and will proceed to San Diego, Cal., and report to the commanding officer for duty at that post.

MIDDLETON, J. V. D., *Surgeon.*—Granted leave of absence for fifteen days.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING SEPTEMBER 5, 1891.

WELLS, HOWARD, *Surgeon.*—Ordered to temporary duty in the Bureau of Medicine and Surgery.

DICKSON, S. H., *Surgeon.*—Detached from the Practice-ship "Constellation," and wait orders.

CURTIS, L. W., *Passed Assistant Surgeon.*—Detached from the "Constellation," and ordered to the Naval Academy.

RUSH, W. H., *Passed Assistant Surgeon.*—Ordered to the U. S. S. "Yantic."

BEYER, H. G., *Passed Assistant Surgeon.*—Detached from the "Yantic," and granted two months' leave.

BOYD, ROBERT, *Assistant Surgeon.*—Detached from the U. S. S. "Dale," and ordered to the Marine Rendezvous, Boston.

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LIX. SATURDAY, SEPTEMBER 19, 1891. NO. 12.

ORIGINAL ARTICLES.

ON THE DIAGNOSTIC VALUE OF LAVERAN'S ORGANISMS.[1]

BY H. TOULMIN, M.D.,

ASSISTANT IN GENERAL MEDICINE IN THE JOHNS HOPKINS HOSPITAL AND DISPENSARY.

WHILE there have been many papers written upon the nature of the organisms first described by Laveran, but few treat of their clinical importance. Osler,[2] Carter,[3] and one or two others, have, however, considered this part of the subject.

A year ago I reported an interesting case of malarial fever bearing on this point, but since that time so many cases have come under observation in which the examination of the blood was of the greatest importance in the diagnosis, that I wish to again bring the subject forward. It will be well to study a few of these cases before going further:

CASE I.—L. B., colored, twenty-five years of age, was admitted to the hospital December 11, 1889, complaining of cough, soreness in the chest, pain in the abdomen, and fever. He had been quite well up to the last week in November, when one day he felt chilly, but had no definite chill; later he became feverish, felt "good for nothing" and tired, and thought he had "taken a heavy cold." His fever continued, and, like the cough, was worse at night. On the 9th of December there was slight epistaxis. He had no chills and no diarrhea, but some abdominal pain, headache and loss of appetite. He was first seen in the dispensary, where it was noted that "his appearance is that of a man with typhoid." The tongue was swollen, dry, and furred; the skin dry and hot; abdomen slightly tender; spleen moderately enlarged; temperature 101.8° F. The blood contained innumerable intra-cellular and extra-cellular bodies and crescents; and when quinine was administered convalescence was immediate.

CASE II.—G. B., a German, eighteen years of age, admitted January 9, 1890; had been ill fourteen days, with continued fever, headache, loss of appetite, but no chills. Examination on admission revealed a condition similar to that in the preceding case: furred tongue, tender abdomen, enlarged spleen, and a temperature of 102° F. It being the fifteenth day of the disease, the absence of spots was not indicative one way or the other. The organisms were found to be abundant.

CASE III.—W. H., an Englishman, twenty-nine years of age, applied at the dispensary September 2, 1890. He seemed in great pain, was apparently very ill, and unable to give an account of himself, save that he had not been well for some days. His tongue was coated and tended to dryness. The pulse was 108 and small, the temperature 104.2° F. There was tenderness in the right iliac fossa, the spleen was much enlarged, and there were râles at both bases. He vomited freely while waiting to be taken to the ward.

His whole appearance was so typical of typhoid that, at the same time a blood-slide was taken, a short while after admission, the order was given to prepare the patient for bathing. To the great surprise of the physician, however, the blood was found to contain a considerable number of crescents. In the meantime the man's head had been closely shaven, preparatory to bathing. During his stay in the hospital his case served to impress everyone most forcibly with the necessity and value of the means of diagnosis adopted. The day after admission he was able to give a history of his illness—which was one of chills and fever of some weeks' duration. Under quinine he made a rapid recovery.

In each of these three cases, from the history and the condition of the patient when first seen, it would have been impossible to make a differential diagnosis between malarial and typhoid fever. Of course, in time, the intermittent character of the fever, which was present in each case, coupled with the therapeutic test of quinine and the absence of Ehrlich's reaction, would have been quite sufficient.

It must be remembered that the intermissions of the fever may only be demonstrated by frequent temperature observations, as was exemplified in Case I. Hence the necessity of such observations.

Even this means of diagnosis may be absent, as is shown in the next case.

CASE IV.—E. P., a colored boy, nineteen years of age, was admitted August 9, 1889. He gave a history of illness of nine days' duration, with headache, backache and pain in the stomach—symptoms of which he complained at the time of admission. On being further questioned he said that he had had *no* chills; his stools had been watery; he had had constant fever and headache; had vomited on two occasions, and had had nose-bleeding on one day. He was dull; the skin was hot and dry; and the tongue furred. There was gurgling in the right iliac fossa. The spleen extended from the seventh rib to the costal margin. The temperature was

[1] Read before the Clinical Society of Baltimore, November 21, 1890.

[2] Transactions of the Path. Soc. of Phila., vol. xii.; British Med. Journal, March 12, 1887: The Johns Hopkins Hospital Bulletin, vol. i., No. 1.

[3] Referred to by Osler, loc. cit.

103.8°, and, though it was taken every four hours, did not reach the normal for four days. There were no chills while in the hospital, nor was there any sweating.

The blood was found to contain a very large number of crescents, extra-cellular bodies and free blood-pigment.

The case is a striking one. All the symptoms and signs were most suggestive of typhoid. In making a differential diagnosis, the therapeutic test and the absence of Ehrlich's reaction would have had to be solely relied upon—the one demanding time, the other far more trouble, apparatus and time than the examination of the blood. Quinine was purposely withheld for several days, as is the custom, in order to observe the course of the disease and to study the organisms. When given, the convalescence was immediate.

CASE V.—C. M., fifty-two years of age, was admitted October 27, 1889, on account of a severe attack of acute colitis. The temperature, which on admission had been 100° F., reached the normal line on the seventh day, though in other respects his condition was unimproved. On the following day there was a sudden rise of temperature to 103.5° F., preceded by chilly feelings. No history of malarial infection could be obtained, but numerous intra-cellular and extra-cellular bodies were found in the blood.

CASE VI.—G. C., fourteen years of age, was admitted November 16, 1889, for epilepsy, with the idea of possible operation. He had had malarial fever during the summer, but for three months had been quite free from chills. His temperature was normal for a week. On the eighth day he complained of feeling chilly, and had a temperature of 101.6° F. Crescents and flagellate bodies were plentifully found in the blood.

These two cases illustrate how easily we may account for sudden rises of temperature during the course of certain diseases. In both instances, but more particularly in the first, it was of the greatest satisfaction to know the cause of the new trouble.[1]

In the surgical wards, also, blood-examinations are always made when there is an unexpected rise of temperature. If the plasmodia are absent, the cause of the fever is looked for elsewhere; if present, as they have been in a number of cases, the anxiety and trouble, which would have resulted had no examination been made, are done away with.

Too often, unfortunately, the chills and fever of a beginning phthisis are, by careless physicians, ascribed to malarial fever. On the other hand, when we may fear that the symptoms are those of phthisis, the presence of the organisms will always set aside these fears—as in the following two cases.

CASE VII.—J. R., seventy years of age, a fisherman, when admitted gave a history of having had a severe cough with expectoration, and occasional chills and fever. He had lost much flesh, and his appearance was that of a man suffering from some chronic wasting disease. There was no enlargement of the spleen to be detected. The temperature was subnormal at many observations. The examination of the lungs gave a negative result, however, and the sputum was free from tubercle bacilli and elastic tissue, but in the blood were many intra-cellular and extra-cellular and segmenting forms.

CASE VIII. is that of a young man now in the wards, who gave a history somewhat similar to the above. He had had no chills for some time prior to his admission, but the cough and expectoration had persisted. His appearance was very suggestive of consumption, and local signs were found in the right lung. As in Case VII. the examination of the sputum for bacilli and elastic tissue was negative, while that of the blood showed the organisms to be numerous. Before these examinations were made the case was considered as in all probability one of phthisis.

To be sure, cases are not frequent in which, from close questioning and careful examination, we are unable to make a differential diagnosis between these two diseases. But it is in the infrequent and atypical cases that we need every means to aid us, and as the examination of the blood is easier and more practicable than that of the sputum, it must at times be of much value.

The following three cases are given to show that repeated examinations of the blood may be necessary and should always be made when any doubt exists.

CASE IX.—J. P., twenty-nine years of age, came to the dispensary complaining of headache, loose bowels, cough, and "chills and fever." His tongue was heavily coated; temperature 104° F.; and, as Dr. Osler noted at the time, "the man had the appearance of a typhoid-fever patient." His blood was examined before he went to the ward, and one intra-cellular body was found. During the following two days the examinations were negative on five successive occasions. As there were no chills or sweats, but only an irregular, continued fever, and the patient was dull and stupid, with tongue heavily furred, we were almost doubting the accuracy of the first examination. On the third day, however, crescents were found; and under the use of quinine he was well in a few days.

CASE X.—C. S., twenty-three years of age, was admitted October 10, 1889. On October 1st she had had a chill, followed by fever. The chill was not repeated, but there were constant fever, headache, malaise, loss of appetite, loose bowels, vomiting, cough, and on one occasion epistaxis. She looked very ill, the skin was hot and dry, the tongue

[1] The quinine administered seemed to exert a decided influence over the primary affection. The convulsions, which had been frequent, were not repeated while the boy was under observation, and the colitis began to improve immediately. This may have been a coincidence.

furred and tending to dryness, the spleen enlarged, the temperature 99.2° F. The blood was repeatedly examined with negative results. The temperature continued high, but was not characteristic of typhoid. Quinine was, of course, not given. Finally, after numerous examinations, extending over a period of many days, crescents were found. Quinine was then prescribed, and the girl immediately and rapidly convalesced.

CASE XI.[1]—L. K., eighty-one years of age, was admitted July 25, 1889, complaining of headache, pain in the back, cold feet and hands. Two weeks before, he had had a mild "sunstroke," which, however, did not cause him to stop work. "There were signs of bronchitis at the bases of the lungs, and in the right interscapular region the note was higher pitched and the breathing tubular." The spleen was not enlarged. After a chill, lasting a few minutes, the temperature rose to 105° F., and for the next three days varied between 101° and 103°. During the morning of the 28th it was subnormal, the pulse irregular and the patient very weak. The case was considered to be one of senile, low pneumonia, as one examination of the blood, on the 25th, had been negative. He grew steadily worse, and died August 2d. But at the post-mortem examination a slight lesion was found at the right base, while flagellate organisms were numerous in the blood.

It is, necessarily, a very difficult matter to say what the outcome would have been had more careful examinations of the blood been made, but no other means would have sufficed to have made more out of the case than was made.

The fact that there are cases in which the organisms, though present, cannot at once be found would seem to detract from the value of this aid in diagnosis. But I have been able to collect only these three cases from many hundreds—and they all occurred when the method and value of the examinations were just beginning to be understood—so that it is more an apparent than a real defect.

Nothwithstanding the fact that such cases may exist, we cannot fail to recognize the importance and value of negative examinations. More particularly is this true when we are differentiating between malarial fever and typhoid. The few examples that have been given are sufficient proof that at times we cannot, by means of symptoms or signs, distinguish between the two. The very general use of the term "typho-malaria" in this part of the country supports this view. Recognizing this to be true, and remembering how much more serious it is to mistake typhoid for malarial fever than *vice versa*, the true value of such negative examinations becomes apparent. I shall not give more detailed cases as illustrations, those already given, especially I., II., III., IV., and IX., need only be referred to. During the last fourteen months the result of the examinations of the blood has, in every case, been the main factor in making the differential diagnosis—without a mistake having been recorded.

Since the introduction, in July last, of the systematic cold-bath treatment in all cases of typhoid, the need of such a sure diagnostic point has been particularly great, and hence its value has increased. In places where typhoid and malarial fevers are both common, it will prove of especial value.

Quite recently there has been an epidemic of typhoid fever in a small manufacturing town adjacent to Baltimore, where malarial fever has been a common plague for years. Many of the workmen, when ill, apply at the hospital. Not infrequently two or more of these men have come together, giving identical histories — or, if stupid foreigners, no history at all—and presenting similar conditions. And still, by means of the blood-examinations, we are able to send one home with the assurance that he will soon be well and able to work, while the other is prepared to undergo a long and tedious illness. Without such examinations we must either detain the malarial patients an unnecessarily long time, while we watch the effect of quinine and study the temperature curve, or send some of our typhoid cases back to work, in the hope that it is only malarial fever—surely, in some cases with disastrous results. When we remember how the two diseases may resemble one another in every particular, and how important it often is for these men to know the probable duration of their illness and when they can be at work again, the truly practical value of such a means of diagnosis is most fully appreciated.

No less valuable are negative results in those cases referred to above, in which we wish to determine whether chills are of malarial origin or are due to suppuration, so that operative interference may be called for. Quite recently a case in point was cited, and no doubt many others similar to it will be recalled. In this instance, in which in the course of an obscure cerebral affection chills occurred, it was "decided to give the patient the benefit of the doubt," and put him on quinine for a few days. The chills continued, an operation was performed, pus was found, but the patient died. It is, of course, impossible to say what might have been gained by operating as soon as examinations of the blood showed that the chills were not the result of malarial infection.

Thus far we have considered the use of this method of diagnosis in only the hospital ward and dispensary. In private practice the situation is different. Means of diagnosis that are available in the hospital are here too often impracticable on account of the time required for their employment or

[1] Reported by Osler in Johns Hopkins Hospital Bulletin, vol. i., No. 1, as above.

for want of proper apparatus. On the other hand, we are far more desirous of making the diagnosis and giving a true prognosis as soon as possible. Again, we cannot rely on the observations of friends or relatives, as for instance, in frequent temperature-taking, but must have means of diagnosis that we ourselves can apply.

Fortunately, blood-examinations are practicable in private practice, and since cases like the foregoing are quite as likely to occur here as in the hospital or dispensary, it is well to describe here the method used:

The drop of blood is taken from the finger-tip or the lobe of the ear. The latter is preferable on account of the skin being thinner and less sensitive. The part selected is washed well and then dried, to remove particles of dirt and sweat. A slide and cover-glass having been carefully cleaned, a very slight prick is made in the skin with a needle or pin. Immediately touch the cover-glass to the drop, without touching the skin, and quickly transfer it to the slide, the object being to prevent crenation of the corpuscles. Gently press or move the cover-glass to destroy the rouleaux, so that each corpuscle may be well seen. It will be found that only a very small drop of blood must be taken to accomplish this end. The sooner the examination is made the better, but the preparation will remain in good condition for two hours, which gives ample time for carrying it to the office or hospital. While the immersion lens brings out the bodies most distinctly, a good one-seventh objective is of sufficient power. With a little practice the preparation of the slide takes but two or three minutes.

The conclusions to be drawn are:

1. There are cases in which, from history, symptoms and signs, we cannot differentiate between malarial fever and certain other diseases.

2. In examining the blood of these cases for the presence or absence of Laveran's organisms, we have a means of diagnosis at once accurate, practical, and practicable.

3. Those cases are rare in which the organisms, though present, cannot be found, and they do not exist at all if the examinations are careful and the examiner has had experience.

THEORY AND PRACTICE OF WOUND-DRAINAGE.

BY N. F. GRAHAM, M.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF SURGERY, MEDICAL DEPARTMENT OF THE HOWARD UNIVERSITY, WASHINGTON.

IT may be laid down as a surgical axiom that, when very free, all wound-secretions should be afforded an easy exit, in order to prevent contamination of the wound by the putrefactive changes likely to take place in them. This is drainage, and it may be natural or artificial. Natural drainage is to be preferred, and is secured by leaving the most dependent part of the wound open; by having wide spaces between the stitches; by making new openings or by allowing the secretions to flow freely from the surface of a sore or superficial wound, or even from deep wounds in which there is no obstruction. Wounds that are allowed to free themselves of secretions in this way should not be obstructed by the dressings used, which should be composed of such materials as will readily and completely absorb the discharges or allow the discharges to pass freely through them.

Artificial drainage is one of the very oldest resources of surgery, and dates back to the early part of the fourteenth century. The *systematic* practice of artificial drainage is of but recent date, and owes its development to Chassaignac, who published his researches and conclusions on this subject in 1859. His teaching and practice were confined to wounds of a septic nature, and his method was simply the removal of purulent secretions by means of perforated rubber tubes. Since his day the practice of drainage has been extended so as to include the removal of non-infected accumulations by this means, with the purpose of removing tension and disposing of products in wound-cavities that might become septic.

The question of the value of drainage in wounds and of the means of best accomplishing it has attracted a great deal of attention during the past few years. There has never been a consensus of opinion on the subject. It is, however, agreed by all that superficial wounds that are allowed to remain open and heal by granuation, intra-peritoneal wounds when aseptic, and wounds in which a blood-clot is purposely allowed to remain, with a view to its becoming organized, do not need to be drained. If the best results are to be obtained, all suppurating wounds must be drained, either naturally or artificially.

Tubes of India-rubber, glass, or metal; silk thread; catgut and iodoformized wick, are the common and familiar materials used for securing drainage. Of these the rubber tube is the most frequently used, as it is the most reliable and most generally adaptable of all the varieties of drainage-tubes. Indeed, the only objection that can be urged against it is that it is not absorbed and therefore has to be removed. For this reason in ordinary aseptic wounds bone drains have been preferred by some.

In suppurating wounds the rubber drain is always to be preferred and should be substituted for the absorbable drain the moment a wound begins to discharge pus. This is because, even in suppurating wounds, bone and similar drains are unstable

and may disappear by absorption, and thus the end and aim of drainage be defeated.

When, at the time of operating, chloride of zinc, carbolic acid, or permanganate of potassium are used as antiseptics, they unduly stimulate a wound and cause a freer discharge of serum than when sterilized water or a mild solution of the bichloride of mercury are used. In former years, before we were so familiar with the value of the bichloride solution and boiled water, the more frequent use of stimulating antiseptics made necessary the more frequent use of drains to carry off the excess of serum that was produced by their use and rendered impossible the methods of dry dressing, now so successful. It is now the rule that, whenever practicable, fresh wounds should, as nearly as possible, be put in the condition of subcutaneous wounds or injuries.

While suppuration will take place in a certain limited proportion of subcutaneous wounds, the number, as compared with open wounds, is so small that Nature's method, as far as possible, should be simulated and such a primary dressing used as will best secure this end. Two indications are to be met in the drainage of wounds: first, the removal of fluids that accumulate in it immediately or soon after the operation. This may be called primary drainage. In the second place, we drain to remove pus and wound-secretions that have undergone septic changes. This we may properly call secondary drainage. Primary drainage is undertaken in the hope of preventing the conditions that render secondary drainage necessary. For the latter purpose tubular drains, preferably of rubber, must be used, because horsehair, silk thread, or spun glass, which act by capillarity, while useful for primary drainage, will not carry off pus or broken-down and softened tissue.

It might be assumed that any wound of considerable size or depth may require artificial drainage, while the clinical facts are that a considerable percentage of wounds, large and small, heal without an undue accumulation of serum or blood, or the formation of pus. Drainage in such wounds is very clearly not required. It is impossible to lay down a general rule that in any given case or even in any class of cases can be relied on, for the important reason that all patients are not alike. The personal equations of heredity, habits, mode of life, previous and present illnesses, etc., are very important factors. Even surgeons of small experience are well aware that many wounds heal kindly without the use of drains, while others prove troublesome even with the most careful management at the time of operation and the judicious use of drainage-tubes. Antiseptic precautions may as well be carried out in the one as in the other; the surroundings and after-treatment may in every particular be similar, yet the results may be very widely different. In the one case the processes necessary to repair go on uninterruptedly to a speedy and complete cure, while in the other we have suppuration and a tedious recovery. These opposite conditions in the behavior of wounds cannot depend wholly upon the operation or the character of the wound, nor can they be attributed to the after-management. This, naturally, should lead the progressive surgeon to study each case independently, instead, as is too often the case, of following a routine plan. The tendency is to run to extremes. One surgeon will place one or more tubes in every wound; another will drain only a certain class of wounds, while a third will abstain from drainage in all his cases.

It has been my experience that a very great proportion of all operation-wounds, made under modern aseptic precautions, and in which proper means are afterward used to keep them aseptic, will heal mainly by first intention, accompanied by but a small amount of discharge of any kind and no pus. On the other hand, the most scrupulous care will not absolutely prevent suppuration.

It is maintained by some of the best surgeons, that if an open wound could be placed in the same condition as a subcutaneous one, the results would be as satisfactory in the one variety as in the other. In his address before the International Medical Congress at Berlin, Sir Joseph Lister said that it would be a great advance if we could do away with drainage, and that the complete fulfilment of his early dream would be realized when our art shall reach so great perfection as to render drainage unnecessary. The practical surgeon of to-day can hardly look forward to the time when all wounds will heal without suppuration; certainly not if he has to rely on imitating Nature's methods as exemplified in the healing of subcutaneous wounds, because a certain percentage of subcutaneous wounds will and do suppurate.

The spontaneous generation of pus is by many good pathologists no longer believed to be possible. They say the infection must come from without by the introduction of pus-cocci, either by their spread along the hair, sweat, or other open ducts, or by their being carried to the injured parts by the blood. It is easy to see how pyogenic germs may be carried along open ducts to any secreting gland of the body, and, when it is in a state of inflammation, cause suppuration, but it is not by any means so plain why one subcutaneous injury will result in suppuration while another escapes. It is rare that pus forms at the seat of a fracture or dislocation, or after the subcutaneous laceration of tendons, though suppuration is common after severe bruises. Every country practitioner is familiar with the abscess commonly

known as "stone-bruise" that forms under the thick skin of the heel of a barefooted boy. There is a certain *tertium quid* that enters as a factor. This, I think, is found in the vitality and resistance of the tissues. Living tissues offer great resistance to microörganisms. On the other hand, bacteria cannot thrive upon the products of decomposition. What they need is dead, but undecomposed albuminoid substances. I think that a careful inquiry into the suppuration of subcutaneous wounds will show that this is precisely the condition that obtains in them. The tissues and cells are crushed in a considerable mass, and by the cutting off of the blood-supply they become dead and constitute a fertile field for the action of pus-cocci. These conditions do not obtain in cases exempt from suppuration, as fractures, etc. While the tissues may be more or less crushed they are not devitalized. No other explanation seems to me to be reasonable. If we admit that pus may form without the agency of micrococci, all our modern theory of pus-generation must fall to the ground.

After bruises and injuries that do not impair the integrity of the skin, pus may form in any locality subcutaneously. Pus has been found in every closed cavity of the body, including even the joint-spaces. It is difficult to see how, through the uninjured skin, infection can occur in such cases. I have seen a bruise, occurring in a perfectly healthy subject free from any dyscrasia, followed by the formation of pus; while abrasions and cuts deeper than the skin, received at the same time, would heal under the dried secretions without a sign of pus. That after injuries tissues will break down and disorganize subcutaneously is a common experience, and so long as such conditions obtain it will be impossible to dispense with the use of drainage-tubes, and just so long will Lister's dream be unfulfilled. It was in this class that Chassaignac, in 1855, used drainage-tubes and recommended them to the profession. They certainly were valuable aids to the surgeon in the days of septic surgery, and when wounds become septic they are yet so. If, as I have said, some subcutaneous wounds will suppurate, is it not reasonable to conclude that wounds treated in every way possible to imitate them will, in a certain proportion of cases, be followed by suppuration? Deeply penetrating wounds that are also contused need drainage from the beginning, because as a rule tissues that are lifeless will break down and become detached from the living tissues and should be allowed easy and safe exit. If, however, by the valuable aid of asepsis and the modern dressing of wounds we shall be enabled to control putrefaction as successfully as Nature does, as shown by the results in subcutaneous injuries, we may feel well satisfied.

What I have said is in the line of conservatism. The drainage of wounds has already been carried to the extreme and much injury has been done by its indiscriminate practice. Clearly, the majority of aseptic wounds do not require to be drained, and just as clearly, a septic wound must be drained. It is impossible to foresee whether a wound will remain aseptic, or what wound will become septic. Could these problems be solved at the outset, the question of the treatment of wounds would be easy. For some years my plan has been to close at once and without drains all clean-cut wounds, such as those made in amputations, the removal of large tumors, breasts, resections, ligations of arteries, etc. I offer Nature a chance, to be interfered with if, as a result of excessive accumulation of serum or blood in the wound cavity, there be an undue rise of temperature with tension; should this condition arise I at once relieve it by removing a stitch or two at the most dependent part of the wound, or by the introduction of one or more tubes. At this time I give preference to the rounded end of a soft rubber male catheter, properly disinfected and perforated. It can easily be inserted into any part of the wound, and, owing to the presence of the smooth rounded end, to the required depth.

A wound may be aseptic, while the discharge of serum and blood may be so great as to make drainage advisable to prevent pressure on the adjacent tissues, the vitality of which might be destroyed by the cutting off of their blood-supply, with consequent necrosis.

In such cases the tube in many instances may be removed in a few hours, often in less than twenty-four, and the healing process goes on uninterruptedly. During the first twenty-four hours or so, a drainage-tube does not exercise the influence of a foreign body in a wound any more than the serum and blood thrown out into its cavity. It is only at the moment when the tissues, the cellular elements, capillaries, etc., have reached the point where repair has just begun, when the first cells have assumed the embryonic state, that the drainage-tube becomes a foreign body, in the sense of interfering with repair. Were it not for the danger of the wound becoming infected by the removal of the dressings for the purpose of withdrawing the tube, no harm for the first day or two could come to any wound by the presence of a clean drainage-tube.

To teach that drainage is *never* necessary in aseptic wounds is not warranted by the facts developed in the experience of every observing surgeon. Wound-cavities, in some instances at least, will become distended by serum and blood to such a degree as to require the withdrawal of the fluid to conserve the integrity of the tissues. A moderate amount of serum is useful and a small amount of blood harmless, while, in some special operations on bone, for

the relief of club-foot, etc., special effort is made by the surgeon to secure a blood-clot, with the view of its becoming organized. However, in ordinary operation-wounds, the smaller the amount of blood, the better. A blood-clot in a wound is more liable to soften and break down than it is to organize. My practice now is, if a blood-clot is found to be present within the first twenty-four hours after an operation, to open up the wound and remove the mass. When I have failed to do so it has often been to the disadvantage of my patient. The following cases, selected from a number, will illustrate this point.

Mrs. R. H. S., aged forty-two, a healthy, well-developed woman, came under observation in May, 1890, in consultation with Dr. Balloch. She was suffering from cancer of the left breast, well advanced, with retracted nipple and a small portion of the skin below the nipple discolored and on the verge of ulceration. I advised removal of the breast, which was done in July, 1890, with the assistance of Drs. Balloch and J. F. Graham. On the morning of the day following the operation she complained of a feeling of tension in the wound. I felt satisfied that a considerable blood-clot must occupy the wound-cavity, but as I had been compelled to remove a portion of the great pectoral muscle in its entire depth, I concluded, in the hope of its becoming organized and thus preventing a sunken and adherent scar, to allow the clot to remain. The superficial cut and all parts not separated by the clot, healed by first intention, but in the course of a week the clot began to soften and I was compelled to open the wound and insert a rubber drain to carry off the blood.

I am convinced, as I was then, that had I opened the wound in the beginning and turned out the mass, I should have obtained a better and speedier result and contributed greatly to the comfort of my patient. Could I have foreseen that blood would be so freely discharged into the wound-cavity, I should have inserted a drain at the time of the primary dressing or placed my stitches wider apart. But when first closed the wound gave no indication of what followed.

As a contrast I will relate the case of Mrs. A., a strong, healthy woman, forty-two years of age, whose breast I removed for cancer some months previously to the operation on Mrs. S.

The variety of cancer was the same, and the condition of the patients as to age and general health very similar. Ten hours after the operation I was summoned to see her and was informed that she was suffering pain and a sensation of tension in the wound. I removed the dressings and found the wound-cavity distended by blood and serum, which were oozing at a number of points between the stitches. I at once removed all the stitches, except one at each extremity of the cut; turned out the blood-clot; washed out the cavity with a weak solution of bichloride; adjusted the flaps and stitched them as before; sprinkled the cut with iodoform; covered it with several thicknesses of iodoform gauze; applied a thick layer of absorbent cotton, and finally a snug bandage over all. She was at once made comfortable, slept well, and at no time did the temperature reach 100°. This first dressing was allowed to remain eight days, and when it was removed it was found that the entire wound had healed by first intention. The stitches were removed and the stitch-holes filled with iodoform. Not a single drop of pus formed during the entire healing process.

While it may be urged that a drain inserted at the time of dressing would have saved the necessity of reopening the wound, I believe the results were as good, if not better, by the method I adopted. I therefore continue to practise it.

The snug adjustment of the walls of a wound-cavity is a matter of no small importance in doing away with the necessity of drainage. Such adjustment, aided by the proper application of suitable compresses and bandages, is very efficient in limiting the oozing from the capillaries and even in controlling the flow of serum into the wound. The conditions that demand drainage in aseptic wounds are thus often obviated.

There is always a mean between two extremes, and, as in anything else, this applies in surgery and surgical procedures. In regard to drainage the middle course is the safe and proper one. Clearly, *all* wounds do not need artificial drainage, and just as clearly *some* wounds should be drained. The surgeon must decide as to the best course in each case. It is here that the judgment of the surgeon is best exemplified. In many cases the after-treatment of an operation-wound requires infinitely more skill and judgment than does the operation itself. I believe there is no other detail of the management of wounds and injuries that is so subject to whims and extremes as this of drainage.

I cannot better close these remarks than by giving the details of a case that lately came under my observation, and that may serve as a warning against the too free and indiscriminate use of the drainage-tube.

M. A., a young and healthy woman, consulted me, in February of this year, for persistent pain and swelling in the right arm, so great as to preclude the use of it in her work, that of a clerk. She gave a history of typhoid fever in 1889, followed by abscesses in both axillæ. The abscess in the left axilla healed spontaneously; that in the right axilla was opened November 1, 1890, by a competent physician of this city. Ever since, she has had pain and swelling as noted. On the humeral side of the right axillary space was a small purple spot, very tender, pressure on which caused intense pain running down the arm to the fingers. I could not

understand the case, and after a routine course of treatment and careful consideration of all the facts, I proposed an exploratory incision, believing that a foreign body was present, most probably a fragment of clothing. After some delay she agreed to this proposition, and on March 19 I made a small incision over the purple spot mentioned, and, after some search, I found the fragment of a drainage-tube. The wound healed kindly, and the patient is now completely well, with full use of the arm.

THE ETIOLOGY OF DYSENTERY: IS IT INFECTIOUS?

BY W. M. GREENLEE, A.M., M.D.,
PROFESSOR OF GENERAL, DESCRIPTIVE, AND SURGICAL ANATOMY AND MEDICAL CHEMISTRY IN THE NATIONAL NORMAL UNIVERSITY OF LEBANON, OHIO.

ALMOST every new epidemic of dysentery revives the much-mooted question as to the causation of this disease. Indeed, it is by means of careful observations, made during such an epidemic, that we may hope at last to arrive at the real truth concerning any of the causes leading to an outbreak of epidemic disorders. The tendency just now, of course, is to ascribe all diseases, and particularly those that make their appearance in epidemic form, to some microbe or special bacillus. While it seems to be conclusively established that some of our worst maladies are at least accompanied by characteristic bacilli, yet it is decidedly unscientific to generalize from such limited observation and insufficient data. I am ready to admit that certain diseases are due to specific microbes—for not to admit this would indicate a blamable obstinacy or a lamentable ignorance. But I also believe that many of these so-called specific germs bear a sequential and not a causative relation to the diseases in the course of which they appear.

This question is of practical importance, since it is very intimately connected with sanitation.

Let us particularize, taking dysentery as an example. Now, if dysentery is an acute disease produced by the entrance of a morbific germ into the human body, we should be forced to admit that it could only be produced by the entrance of such a germ, and that we could only have dysentery present when we had this special germ present. Otherwise it would not be a specific germ. That is to say—the disease cannot be produced by simple violations of hygienic laws *and* by a specific microbe, etc. The two causes are incompatible, in the very nature of things, since a bacillus requires a suitable nidus in which to develop, and cannot, of course, be developed when a person is merely careless about his food, clothing, etc. Therefore, the proof of the existence of one class, sustaining a causative relation, does away with the other class as a possible factor.

If, then, we can prove that a disease is caused directly by a violation of the simple laws of hygiene, we know that any germs that may appear in the course of the disease are a consequence and not a cause. This is where sanitary science comes in. If dysentery is due to a germ, then improved sanitation may hope to destroy all possible sources of infection. But, suppose we depend upon improved sanitary measures when the cause is not a specific germ, we shall find the disease appearing in spite of the most vigorous preventive measures.

Notes taken during a recent extensive epidemic at this place, and the study of other epidemics, suggest the following facts:

1. Dysentery makes its appearance in towns and villages almost perfect in their sanitary condition. It is a noteworthy fact that epidemics of dysentery appear in our smaller towns, perhaps with even greater frequency than in our large cities. The cause of this will be pointed out further on. We also know what a common and fatal disease dysentery was during the late war. The soldiers were certainly not subjected to what might be termed bad sanitation, except in those cases in which the disease appeared in crowded prisons.

2. Dysentery is a disease that shows a decided tendency to appear in epidemic form during a season when fruit is unusually abundant, following a year or two characterized by a marked failure in all kinds of fruit. This is true of the epidemic just closing, and the same fact has often been noted with regard to others.

3. Dysentery seems to break forth during the latter half of summer and follows a season characterized by severely hot days and very chilly nights. It will thus be seen that the conditions under which an epidemic of dysentery appears are just those most often met with in our smaller towns and in country districts. People engaged in hard work in the day and in the habit of sitting in their sweat-saturated garments, without coat and hat, are usually the victims of this epidemic. My notes show that by far the greater number of cases treated during the outbreak here presented a distinct history of over-indulgence in green fruit, repeated time and again. The first trouble occasioned by such over-indulgence was a simple diarrhea. This would moderate, and then the same process would be gone through again until dysentery would finally develop. I had several of the medical students take complete charge of the nursing of some of the worst cases. They even emptied the discharges, and had every opportunity of receiving into their systems the causative germs, if there had been any. Not one of these contracted the disease. It is all the more significant when I state that I had told them to eat no fruit and to be very careful both as to diet and the changes from the heat of the day to the cold of the night.

It would seem that dysentery is most probably a disease arising from violated hygiene alone, and should be combated by teaching the necessity of greater care in what is eaten, as well as the avoidance of all sudden chills.

ORIGINAL LECTURE.

LOCOMOTOR ATAXIA.

Abstract of a Clinical Lecture delivered at the Bellevue Hospital.

By W. H. THOMPSON, M.D.,
VISITING PHYSICIAN.

Gentlemen: These two cases will form the text of our lecture to-day. The first patient tells us that he has been sick for about one year, and that he first noticed a pain in the back, then difficulty in walking, and later on pain in the calf of the leg. He has had no pain in his side, and no headache. Urination is sudden, frequent, and burning, and the act is prolonged. There is a sensation of numbness about his feet.

This other man says that he has had quite severe pains in the bowels and back, and occasional attacks of vomiting; that there has been a feeling as though a tight cord were tied about his waist, and that walking has been difficult, for about one year. He thinks that his legs are weak or paralyzed, but you notice that he can flex and extend his legs, even against great resistance. He has had no choking spells. He has noticed that his eyes watered when reading, and that occasionally he saw double; but the two objects did not always occupy the same position with reference to each other. In addition to these symptoms, he tells us that he has had severe pains up and down the legs; and I wish you particularly to notice his gestures while describing these pains, for they are very characteristic. Always accustom yourselves to watch a patient's gestures very closely, for they will often give you important hints as to the nature of the pain. Thus, when a man complains of pain over his chest, and indicates its situation by placing the flat of his hand over the spot, the pain is most probably due to bronchitis; whereas, if he *points* to the spot with the tip of the finger, locating it very particularly, the pain is likely to be of pleuritic origin. Again, if a patient tells you that he has pain in his knee, and at the same time grabs the knee with his hands, you may be sure that the pain is not due to rheumatism, for rheumatism is an inflammatory affection, and the patient takes hold of the painful part much more tenderly. Such a gesture would be more often indicative of neuralgic pain. You notice that this patient's gestures indicate not only neuralgic pain, but pain of a particular kind, and very characteristic of the disease which we have under consideration—he describes the pain as shooting *up and down* his leg. More commonly, however, in locomotor ataxia, this pain shoots in one direction.

The disease we are studying to-day is called locomotor ataxia; but it is highly important to remember that the ataxia is, in many cases, by no means an early or prominent symptom, and owing to the Protean manifestations of this disease, mistakes in diagnosis are very common. By ataxia is meant a want of discipline between the muscles. They are no more paralyzed than are the muscles of an intoxicated person. Every muscular action of ordinary life is the result of long training of the muscles to work in unison, and to secure such a result requires the most delicate and harmonious adjustment of the opposing muscles. The "mental muscles" are those that carry out the purposes of the conscious mind, and these muscles are the first to show any lack of co-ordination. In the common act of sneezing, for example, an afferent impression starts from the nose, and calls one hundred and ten muscles into play to carry out the act. At first there is a long, steady action of the diaphragm until a considerable quantity of air has been taken in, then word is sent to all the muscles of respiration to be ready, and act in an orderly manner. If at this moment the person were tickled in the side, the muscles in this region would be prevented from acting in concert with the others, and the sneeze would not be a success.

Locomotor ataxia is due to a lack of discipline in the muscular system, and before the ataxic symptoms are at all prominent, such actions as require considerable co-ordination of the muscles, as, for instance, buttoning the coat, are performed not in a hesitating, but in a very hurried way.

The symptoms of locomotor ataxia are conveniently divided into three classes—viz., sensory, visceral, and ataxic; and the existence of this disease is to be suspected whenever any one of these three varieties is present.

(1) Sensory symptoms. These symptoms are especially characteristic of locomotor ataxia, and they may be the only ones. By these symptoms I was enabled in one case to predict the occurrence of ataxia eight years before it actually appeared. These symptoms are neuralgic and not inflammatory, and the patient will often localize them by pointing in the manner already noticed in the second patient, and describe them as being of a boring character. The "crushing" pains are more likely to be felt in the extremities, just above the ankle. The sensation of constriction is often felt just above the ankle or wrist, but when it is around the body, like a tight cord, it indicates a myelitis. Very often the patient will localize the pains with his finger, and speak of that spot as being very painful—yet an examination will often show that the area is really anesthetic. Similar areas may be located around the chest, and this symptom is often mistaken for an indication of some pulmonary or cardiac affection. These severe neuralgic pains often vanish quite suddenly. Another very characteristic kind of pain is the "lightning pain," that by many patients is described as very similar to that produced by an electric shock. These may at first be the only indications of locomotor ataxia, but they are sufficient for a diagnosis, and the other symptoms will develop later. In our first patient these sensory symptoms, although usually most important, are by no means prominent.

(2) Visceral symptoms. The commonest of all the symptoms of this class are those referred to the bladder. The mode of micturition has been already described by these two patients. The pain is usually felt toward the close of the act. The most frequent mistakes in diagnosis occur in connection with the stomach, which is often involved in what are known as "gastric crises," the patient being attacked at short intervals with all the symptoms of cholera morbus, accompanied by great

prostration. Quite commonly the bowels are also involved. When the larynx is affected, the patient suddenly awakens with a choking sensation due to spasm. The condition of the sense of vision is particularly important, and although this first patient told us that he had no trouble with his eyes, examination shows a highly interesting condition of the pupil, known as the Argyll-Robertson pupil, from the fact that he first directed attention to this symptom in locomotor ataxia. This phenomenon is observed in about thirty per cent. of these cases. The pupils are contracted—usually symmetrically—and insensible to light; but on asking the patient to read anything close to the eye, particularly fine print, the pupils contract during the effort of reading. Often the first sign of ataxia is seen in the eye. If a patient sees double because of permanent paralysis of the muscles of the eye, the relation of the two objects which he sees remains the same; but if the double vision be due to the fact that the muscles of the eye do not work in harmony, the images do not always bear the same relation to each other—sometimes being side by side, and at other times one above the other—this form of double vision is called "ataxic diplopia," and is very characteristic of locomotor ataxia.

(3) Ataxia. Although the patient's gait may be good, one can almost always elicit some evidence of ataxia. For instance, ask the patient to sign his name, and then ask some one familiar with his signature if the handwriting is the same as formerly. Usually, it will show a very firm down-stroke and a wandering up-stroke. Again, if ataxia be present, and you request the patient to button his coat, the motions of the fingers will be very precipitate. If asked to put a pin through a piece of paper, he grabs the pin as though it were a skewer which he was going to push through a piece of meat. If he attempts, with his eyes closed, to place one finger upon the tip of the nose he will be apt to miss his aim and strike the side of the nose, as you notice this second patient does. Similarly, when he attempts with his eyes closed to place his fingers tip to tip, he will be unable to do so. The first patient when tested in this way, does not show much incoördination.

Even if all three classes of symptoms described are absent, or are discovered with difficulty, there is one symptom that is very rarely absent—*i. e.*, the absence of the patellar reflex. You notice that neither of these patients exhibits such a reflex. There are very few other diseases in which it is absent. The most common one is diphtheria, and here the reflex may be absent for two months after the attack. It is also absent in peripheral neuritis due to other causes than diphtheria, and the most common of these are chronic alcoholism and poisoning by lead or arsenic.

CLINICAL MEMORANDA.

A CASE OF LUPUS OF ELEVEN YEARS' STANDING CURED BY THE TUBERCULIN TREATMENT.

BY M. MAGELSON, A.M., M.D.,
OF FERGUS FALLS, MINN.

MRS. O. A. is thirty-four years old, and has had seven children. In the spring of 1880, after exposure to cold and wind, she noticed soreness in and about the nose; the left ala of the nose became red, and sores formed which were covered with crusts; the sores healed and again broke out, and, after some time, the nose seemed to melt away. In the following years the sores spread over the face, healing and breaking out again in different places. When I first saw her on the 14th of March, 1889, the whole lower part of her face, from the place where the alæ of the nose should have been, round the mouth and down to the lower edge of the chin, was one continuous sore, partly covered with greenish crusts and partly showing red sparingly secreting surfaces without granulations, and with small, whitish nodules at

the bottom of the sores. The sore extended to the left eye, the lower lid of which had been entirely eaten away; there was also a considerable loss of substance at the right angle of the mouth, so that the saliva and food during eating were constantly coming out over the ulcerated edge of the lips. The upper lip was ulcerated down to the gingiva. The nose was entirely lost, the openings of the choana being covered with a membrane of scar-tissue, in which there was an opening, one-eighth of an inch in diameter, into the left nasal cavity. This membrane was partly covered with sores and crusts. There was a swollen gland under the left side of the lower jaw-bone. At this time she weighed one hundred and seventeen pounds, and was nursing a four-months'-old baby. She complained of some pricking in the sores, and of a tight feeling in the scar-tissue. Physical examination proved that her lungs were healthy. Her family history is good, her parents both living, past sixty years of age. By Ehrlich's method I found tubercle bacilli in the whitish nodules of the sores, and advised her of the nature of the disease, which had before been pronounced cancer, and treated with escharotics. I scraped out the sores with a sharp spoon, and applied iodoform ointment, 10 per cent., and ice compresses, and gave her internally arsenic in increasing doses, with some remissions during the summer. The sores healed up around her mouth, where I had done the scraping, and on the chin, and she was able to eat with greater ease. From this time I occasionally heard from her; she was living in Dakota, more than sixty miles away, but she was not getting

well, though the treatment was kept up on the same lines, and the sores were occasionally scraped by her physician. Some sores would heal, but new ones would again break out in the scar-tissue. As she notified me this spring that the disease was spreading over her whole face, and up on the forehead, I advised her to come to Fergus Falls and be treated with tuberculin. She arrived on the 11th of April, and from the upper border of the forehead to the lower surface of the chin, and from one ear to the other, the whole face was covered with sores and crusts. As I did not intend to rely upon the tuberculin alone, 10 per cent. aristol ointment was also applied, which, after a month, when the watery secretion from the sores became excessive, was changed to a strength of 5 per cent. Under local anesthesia in the beginning I used the sharp spoon on the sores. Pyoktanin was used afterward, and a 2 : 1000 solution of corrosive sublimate before and after the pyoktanin application. I also used Peruvian balsam to stimulate the development of healthy granulations. Internally, I gave Fowler's solution in increasing doses up to twenty-four drops three times a day. So far as the effects of the tuberculin were concerned, she showed the reaction described by Prof. Koch after the initial dose of 0.001 gram. After repeated inoculations every second, sometimes every third, day, the reaction was less, and from the 7th of May the dose was raised to 0.003 gram, and on the 28th of May to 0.005 gram. As the reaction was then very slight, I should have gone on increasing the dose, but as on the 3d of June she recognized movements of the fetus, and as the sores were healing, I suspended the tuberculin treatment. On the 13th of June all the sores were healed. I could not induce her to have her photograph taken when she first came under treatment, but the scars on the picture herewith reproduced, will show the extent of the sores. I had meanwhile several times tried by skin-grafting to cover the defect of the lower left eyelid, but the tears that saturated the different dressings applied frustrated my efforts. The dentist helped me to have an artificial nose and upper lip made, and the eyes were covered with London smoked glasses. The contraction of the scar-tissue has everted the lower right eyelid some, which, after her confinement, I intend to correct by operation. When she left, she seemed to enjoy perfect health, and weighed one hundred and twenty-seven pounds.

On the 8th of August she wrote me that her health was good, and that no new sores had formed.

YELLOW FEVER IN RIO.

By R. CLEARY, A.M., M.D.,
of Rio de Janeiro, Brazil.

Although I have nothing new or specific to offer for the treatment of yellow fever, yet because I have had some experience with the disease, and have familiarized myself with the practice of some well-known and successful physicians in this place, I would like to present a synopsis of a treatment that has been certainly not less successful than any other, both in my hands and in those of other and better known physicians.

That the pathogenic microörganism of yellow fever has not yet been discovered, or, at least, verified, notwithstanding the close and long-continued studies of Sternberg, Gibier, Carmona y Valle, Lacerda and others, must, I think, be accepted by the greater part of the thinking portion of the medical profession.

Dr. Sternberg has announced that he encountered no less than ten microörganisms in the alimentary canal alone, of cadavers dead of yellow fever, and that not one of them is pathogenic of the disease.

The epidemic of 1889, here in Rio de Janeiro, was very extensive, though less malignant than the one we have just passed through (1891); it was more extended over the town, but not so proportionately rife amongst the shipping, and whilst the death-rate was much greater, so great was the number attacked that the mortality per cent. was much less.

Although it is difficult to arrive at anything like certainty, I gather that the deaths were not more than 8 per cent. of all the cases, whilst in 1891 the deaths certainly were from 15 to 20 per cent. I do not give these figures as statistics, because, for well-known reasons, it is impossible to reach a definite conclusion, but they are only intended as opinions, and can be taken at what may be considered as their value. Of the thirty-four undoubted cases I treated in 1889, I was fortunate enough to lose only one, and most of them were foreigners newly arrived, and totally unacclimated in Rio. I adopted the usual symptomatic and expectant treatment, with the addition of Dr. Sternberg's alkaline and mercurial solution, which appeared in most cases to act like a charm. It was, however, apparently without effect in those cases in which it was only used late in the course of the disease.

In the epidemic of 1891 the disease appeared to take on a more malignant type, *all* the worst symptoms frequently appearing during the first twenty-four or thirty-six hours. As an example of this, take the following case:

On March 30th, at 5 P.M., I was called to Mr. T. H. A., an American, twenty-seven years of age, weak and much reduced by the abuse of alcoholic beverages, and only a few months in the country; the temperature was 39° C.; pulse 100, and every usual symptom more plainly marked than is customary. On March 31st the temperature was 38.8° C., pulse 82, all the symptoms intensified, streaks of black in the vomited matters, and the urine scanty. On April 1st the temperature was 37.5° C., the pulse 80, the skin moist and clammy, a total suppression of urine since the previous night, profuse, black vomited matter, and he was delirious. He died April 2d, at 7 A.M. This was a rapid case, was not singular by any means, and was, as the Brazilians graphically express it, "*fulminanto.*" It was treated on the principles that guided us in other cases, and no time was lost.

The following case is a typical one, and, as it embraces almost every emergency, I will give it in full, as a fair sample both of the disease and of its treatment:

Mr. C. H. L., an Englishman, thirty-two years of age, small and compact, but not weak, temperate in his habits, and about one year in the country, was attacked on May 4th. I saw him at 7.30 P.M., and found him with a temperature of 40.5° C., pulse 120, excessive frontal headache, pain in the back, extending down the thighs, eyes very much suffused and protuberant, skin moist and clammy, hyperemia and stagnation of the capillary circulation on the upper, front part of the chest.

This symptom was pronounced pathognomonic by Baron Torres Homem, the great Brazilian authority on the subject.

His bowels had not been moved for three days, and I gave him calomel 0.33 gram, with sodium bicarbonate 0.25, followed by three Russian capsules of castor oil in two hours, and antipyrine 0.50, ammonium acetate 2, and tincture of aconite one-half drop every two hours. On May 5th the temperature was 39.8° C., pulse 120, and weak, all symptoms exaggerated, and with great nausea; the bowels had been copiously moved four times. I gave him of mercuric bichloride 0.02, sodium bicarbonate 10, boiled water 1000, two tablespoonfuls every two hours, ice-cold, alternating with Murray's fluid magnesia 200, magnesium salicylate 2.50, tincture of aconite 10 drops, tincture of digitalis 2, a tablespoonful every two hours. Besides, for the nausea, he was also given of chloroform (pure) 25, camphorated alcohol 25, four drops in a teaspoonful of cold water. I also ordered the lower intestines to be washed out four times a day with boric acid 10, β-napthol 1, boiled water 1000. The antipyrine mixture was given occasionally to lower the temperature. On May 6th the temperature was 38.8° C., the pulse 82, and the stomach more quiet. He vomited once, the ejected matter presenting black streaks. The pains were now much easier, and there was a yellowish tinge in the eyes and upper part of thorax. As there has always been a decided rise of temperature toward nightfall, in addition to the previous treatment, quinine sulphate was given in divided doses. The urine contained some albumin. On May 7th the temperature ran up to 38.9° C., the pulse was 84, and there was about 15 per cent. of albumin in the urine. I continued the treatment, and as the chloroform and camphor had no more effect, I gave of cocaine chlorhydrate 0.10, Murray's fluid magnesia 200, a tablespoonful every two hours, or *p. r. n.* The urine became very scanty. I gave two hypodermatic injections of caffeine citrate 0.33, with an interval of two hours; at nightfall he urinated abundantly. On May 8th the temperature was 37.9° C., the pulse 72, the skin moist and soft, the tongue cleaning, the yellow tinge decided and dusky, and there was about 20 per cent. of albumin in the urine. I gave of aqua rosæ 160, tannin 2, alcohol 10, syrup of tolu 30, a tablespoonful every two hours, always preceded by salol 0.25 for the excess of albumin in the urine, alternating with the magnesia mixture prescribed on the 5th. As the temperature again rose to 39.8° at night, two capsules of antipyrine, each 0.50, were given, with an interval of one hour. On May 9th the urine was very albuminous—perhaps 40 per cent.—the temperature 37.4°, the pulse 68, the stomach quiet, very weak and nervous. I continued the treatment. On May 10th the quantity of albumin in the urine was less, the temperature 37.5,° the pulse 66. From this date he became convalescent, and was put upon a tonic; he rapidly recovered strength, although the case was complicated with an attack of malarial fever, and followed by congestion of the liver.

The diet all through the disease was iced boiled milk, in small quantities, seltzer water, and, when it appeared to be needed, a little brandy occasionally.

The accessory treatment was mustard plasters, small blisters, injections or intestinal washings of boric acid and napthol; and, as the magnesia mixture and Sternberg's mercurial, alkaline potion were disinfectant and antiseptic, thus the whole alimentary canal was always disinfected.

I have found brandy preferable to champagne, since the latter often adds to the already acid condition of the stomach, even though it apparently does good when it is taken. It is well known that the force of the attack in yellow fever is upon the alimentary canal; hence our rational treatment must be directed in accordance with this idea, though symptoms must be combated as they arise.

The two symptoms often fatal are suppression of the urine and black vomit, which is another name for hemorrhage. For the first, besides some diuretic medicine, hypodermatic injections of caffeine appear to act best in most cases, assisted by turpentine stupes to the lower part of the spinal column, frictions, hip-baths, etc. It is said that an able physician here has prescribed small, ice-cold clysters, so that they are retained near the bladder, but I have never used them with this object.

For the black vomit it is the rule to give ergotine, tincture of iron or gallic acid, but I believe they are of little benefit, and have found that by quieting the stomach with cocaine and counter-irritants, we are more generally successful, though as a routine practice, I always prescribe gallic acid, and have seen it apparently have good effects.

As for the quinine treatment, it is little used here, and, I must say, I have never seen one case benefited by it when used in the beginning, though in the third period of the disease its use is very frequently beneficial.

To return to the subject of black vomits: though I have never seen it used, or heard of such a thing, why may not *hot water*, as hot as it can be borne, stop the hemorrhage from the stomach, as surely as it does that from the uterus *post partum?*

SKIN ERUPTIONS FOLLOWING THE USE OF QUININE SULPHATE.

BY EDWARD A. WELCH, M.D.,
OF POTTSTOWN, PA.

THE following cases of skin eruption, due to the administration of quinine sulphate, are reported in the belief that the general practitioner should place on record careful observations of all instances of abnormal or unusual results following the use of drugs:

CASE I.—At 8 P.M. of January 30, 1891, J. W., a school-boy, fifteen years old, took gr. iv of quinine sulphate for the purpose of "breaking up a cold." I had seen him half an hour previously, and, with the exception of an incipient coryza, he seemed in perfect health, his temperature being 99°. At 9.30 P.M., an hour and a half after taking the quinine, the lad called on me in great alarm, with the statement that "he had the scarlet fever." His temperature was 99.6°, the pulse rapid, and he was in a decidedly nervous condition. On examination, I found his body (front and back) covered with an erythematous eruption of a bright, vivid-red color, disappearing on pressure, but returning immediately, and in many places closely resembling the rash of scarlatina. The surface of the skin was also decidedly hyperesthetic, a condition not present in the boy's normal state. He

stated that when he first noticed the rash, some ten minutes before, it was mostly on his neck and upper part of the chest, and seemed to be spreading rapidly. Further examination showed an efflorescence on legs, arms, feet and hands. A number of small, flat wheals, of the size of a pea, were at first visible, scattered at intervals over the body, but these to a large extent disappeared during the hour and a half that the patient was under observation, and became merged in the general erythema. The eruption, which was at first "patchy" in character, rapidly became confluent, and at length almost the entire surface was of a uniform, bright-red hue. Accompanying the eruption was an intense prurigo, so severe that the patient was with difficulty prevented from continual scratching.

A sedative and cooling ointment was applied, and the boy sent to bed. The next morning the eruption had almost entirely disappeared, and the boy was as well as ever, while in another twenty-four hours all traces of the exanthem had vanished.

Recognizing the possibility of a skin eruption due to errors of diet, I made a careful search for such possible cause, but could find none. The case seems to have been one of quinine eruption, pure and simple.

CASE II.—J. K., a school-boy, eighteen years old, at 7.30 P.M., on March 18, 1891, took grs. viii of quinine. At 10 P.M. there was noticed an erythematous reddening of the whole body, with occasional distinct spots (one-quarter to three-eighths of an inch in diameter) of a deeper color. There was no elevation of temperature. On the following morning the erythema was still persistent, disappearing momentarily on pressure. There was also at this time considerable prurigo. Examination of the membranes of the mouth, tongue and throat showed no departure from the normal condition. The redness gradually disappeared during the next two days, but the prurigo was sufficiently marked to be uncomfortable until the 22d. The attack was followed by moderate, flaky desquamation of the epidermis. No other probable cause than the quinine could be ascertained.

CASE III.—W. H., a student, nineteen years old, was not feeling well when, on May 16, 1891, he went to Philadelphia to visit friends. "Sunday night, noticing symptoms due to a cold, he took grs. x of quinine sulphate. In a few minutes he began to itch excessively all over the body. This was soon followed by nausea and repeated vomiting. He also had several diarrheal movements. During the vomiting he experienced a prolonged and rather severe chill. Later, after the nausea had subsided, he was hot and feverish, with some perspiration." On the following morning his Philadelphia friends noticed a rash on his face and neck; but there was no trace of this when I saw him some hours later, nor had he at that time any fever, prurigo, or symptoms of an exanthem.

I include this case with the others, although it did not occur while the boy was under direct observation all the time, as was the case with Nos. I. and II., and hence there was not the chance for certain exclusion of other agents than the drug.

Dr. Allen J. Smith has been elected Professor of Pathology in the University of Texas.

A CASE OF IMPACTED FECES; LAPAROTOMY; DEATH.

BY J. HERBERT DAREY, A.M., M.D.,
OF GRANGER, MINN.

ON the 20th of May, 1891, I was called to see Annie M., a little girl ten years of age, on account of a tumor that her parents had discovered in the left inguinal region. She had a history of having had the "grip" last January, and of having ever since a pretty constant and profuse diarrhea that nothing seemed to check. She had considerably run down in flesh, but continued to go to school. At times she would have severe attacks of cramp that doubled her up "like a jack-knife." Otherwise the personal and family history was good.

On examination a hard, nodular, freely movable, flattened tumor, painful on pressure, the size of an orange, was found in the left inguinal region. I advised a consultation with Dr. Kessel, of Cresco, which was agreed to by the parents. We suggested an operation for the purpose of finding out the nature of the tumor, and removing it, if possible. We had an idea that we should probably find a dermoid cartilaginous cyst, with a long pedicle, as the tumor was very freely movable.

On the 5th of June, after thorough preliminary antiseptic precautions, I performed a laparotomy, assisted by Drs. Kessel and Connolly. Ether was used, with a little chloroform at times, when the patient would not take the ether well. An incision from the pubes to the umbilicus was made, and after careful dissection through the sheath of the rectus and the aponeurosis of the transversalis muscles, the peritoneum was opened. The first thing that presented itself was the descending colon, filled full of hard, impacted feces. A loop of the colon was drawn out of the abdomen, and still a tumor could be felt from the outside. Upon exploring further, this tumor was found to be another loop of intestine, with impacted feces in it. The abdominal cavity was carefully explored, but nothing further could be found. The colon, from the sigmoid flexure for a distance of nine inches upward, was filled full of hard feces, and distended to a size of two and a half inches in diameter. The fecal mass in the center was about the consistence of rather stiff putty; but at both extremities, and particularly the lower one, it was so hard that no impression could be made in it with the fingers. It felt as hard as a stone. The abdomen was then sewn up with five deep and five superficial sutures, and the patient put to bed with hot-water bottles around her. The wound was dressed with a little iodoform and bichloride gauze, a good pad of absorbent cotton, and a roller bandage over all. She came out of the ether well. The temperature in the evening was $99\frac{1}{10}°$, the pulse 110. She made a good recovery from the operation. On the sixth day she had an elevation of temperature to $101\frac{2}{10}°$, due to a very profuse diarrhea.

The superficial stitches were removed on the sixth day, and the deep ones on the ninth. From the fourteenth to the seventeenth day she had an elevation of temperature that looked on the chart very like the rise of temperature in typhoid fever—1° higher every evening, with a good remission in the morning. The highest point the thermometer indicated was 103½°. This rise disappeared by lysis, and she seemed to be doing nicely. Two

weeks after the operation, I began to use injections with the rectal tube and the syringe to try to soften and dislodge the mass from below. The method I followed was to inject a half-pint of fresh ox-gall to soften the mass, and in half an hour to follow it up with a quart of warm water. It seemed to work very well. Every day some fecal matter, in the form of little, hard pellets, would come away that looked like the hard mass softened down. On the twenty-third day fully a pint of softened feces came away, and I was getting greatly encouraged and hopeful that I would succeed in removing the whole mass in time. The patient was doing remarkably well, too, sitting up in bed a little, writing letters, etc. But on the afternoon of the twenty-fourth day she began to vomit, and her temperature ran up to 102°. I gave a hypodermatic of morphine, ⅛ grain, and the next morning it fell to 100°, pulse 136, feeble and compressible. I had a consultation with Dr. Kessel. There was a good deal of tympanites, the abdomen was extremely tender to the touch. The hypodermatic of morphine quieted her stomach. I gave some bismuth subnitrate, three-grain powders, every two hours. After consulting with Dr. Kessel, we put her on fifteen drops of laudanum every hour. I stayed with her through the night, and gave the medicine myself. The respiration had been 40 to the minute, and under the laudanum I reduced it to 20. But the pulse did not come down much, staying over 100 all the time. Gradually she failed, and died at 2.30 A.M., on the twenty-fifth day after the operation.

This was a very instructive case to me. The operation was, I think, fully justifiable to determine the nature of the tumor. The profuse diarrhea was very misleading, and the tumor itself was so extremely hard that we never suspected impacted feces. In fact, I don't see how a diagnosis could have been made without the operation. That she had fully recovered from the operation is proved by the time that had elapsed before the fatal peritonitis set in. The only wonder is that with so large an impaction in the bowel it had not occurred months before.

CURRENT LITERATURE.

SPECIFIC GRAVITY OF THE BLOOD IN DISEASE.

QUESTIONING the reliability and practicability of the methods of determining the specific gravity of the blood that have hitherto been employed, SCHMALTZ, of Dresden, has adopted the pyknometric method as the most exact. For this purpose he employs capillary tubes of special form, with a capacity of about one-tenth of a cubic centimeter. In one case the specific gravity of the blood obtained by venesection, taken with a large instrument, was 1040.98, and with the capillary instrument 1041.48. As a result of 55 examinations of his own blood, and of examinations of the blood of 20 persons of both sexes, Schmaltz has found that the density of the blood is very little, if at all, influenced by taking food or fluids (including a quart of physiological salt solution), by intense bodily exertion, and the development of hyperemia of the skin at the point from which the blood is to be drawn. The specific gravity of his own blood was somewhat higher in the morning than later in the day, the greatest difference being included between 1056 and 1062.1, and being apparently independent of food and drink. The average specific gravity of the blood of 8 men was 1059.1, and of 12 women, 1056.2, showing a lower range for women than for men. The specific gravity remains fairly constant in healthy persons.

Schmaltz has tested the specific gravity of the blood of 95 patients, mostly women. 29 were chlorotic women with anemia, more or less acute, without known cause. In 9 of these the specific gravity of the blood fell below 1040, and in 2 below 1035. In the remaining 18 cases the specific gravity ranged from 1035 to 1049.

In 21 cases, existing anemia was known to have been a result of hemorrhages and severe blood-diseases. The figures obtained were higher than in the case of the chlorotics; 2 patients died; 1 had leukemia and endocarditis (sp. gr. 1034), and one septicemia and endocarditis (sp. gr. 1030). In 1 case of hematemesis, the specific gravity was 1031; in 1 of carcinoma of the stomach and liver, 1039, and in 1 of incipient phthisis it was 1036. On the other hand, in a case of severe metrorrhagia, in which the patient, who, a short time before the blood was examined almost died in collapse from hemorrhage, and was extremely anemic, the specific gravity of the blood was 1042. In the other cases—heart disease, Bright's disease, typhoid fever, etc.—the specific gravity ranged from 1039 to 1049

In a series of 33 cases, including one very anemic patient, all of the organs of whom were healthy, cases of dilatation and of ulcer of the stomach, tertiary syphilis, progressive phthisis, valvular lesions of the heart, diabetes, marasmus, articular rheumatism, and 2 convalescent cases, one of pleurisy with effusion, and one of acute bronchitis, the specific gravity of the blood suffered no material diminution, and in 2 or 3 cases was even abnormally high—1063 (progressive phthisis and heart-disease). Some of these cases lend support to the view of Oppenheimer, that when the proportion of hemoglobin and the specific gravity are normal, though the patient be anemic, there must be an abnormal distribution of the blood. It must be borne in mind that in some cases the specific gravity of the blood rises during inanition. In other cases, conditions of blood-stasis, such as occur in phthisis and in heart-disease, raise the specific gravity in the areas of stasis.

In 26 cases Schmaltz compared the specific gravity of the blood with the percentage of hemoglobin and with the corpuscular richness of the blood. He found that a lowering of the specific gravity goes hand-in-hand with a diminution of hemoglobin, while the specific gravity is in a large degree independent of the number of red blood-corpuscles.

In 4 cases of chlorosis cured, the specific gravity rose until it became normal; in other cases it increased, but failed to reach the normal without the disappearance of the other symptoms.

As a result of his studies, Schmaltz formulates the following conclusions: Under normal conditions the specific gravity of the blood in man varies within narrow limits; as a rule it diminishes considerably in anemic conditions, especially in chlorosis and diseases of the blood proper; the density of the blood is chiefly determined by the quantity of hemoglobin present, while it is in a large measure independent of the number of

red blood-cells; with improvement in the anemic condition the specific gravity of the blood rises, and with complete recovery attains the normal. It seems, therefore, that the specific gravity of the blood is an accurate index of the condition of the disease; when the circulation is retarded in the extremities—for example, in diseases of the heart and lungs—the specific gravity of the blood is not rarely elevated, and may, in spite of persisting anemia, be found normal. — *Deutsche med. Wochenschrift*, No. 16, 1891.

[Schmaltz describes his "capillary pyknometer" and his method of using it in the *Deutsches Archiv für klin. Medicine*, Bd. xlvii. 145. A capillary tube containing distilled water is weighed, the water is expelled and the tube again weighed—the difference in weight, of course, is the weight of the water. In the same way the weight of a capillary tubeful of blood is obtained. The weight of the blood and of the water being thus known, simple division gives the specific gravity.]

MEDICAL PROGRESS.

The Abortive Treatment of Buboes.—Welander (*Archiv f. Dermatol. und Syphilis*, No. 3, 1891) reports a second series of fifty-nine cases of bubo treated by means of injections of benzoate of mercury. In all, he has now treated one hundred buboes in this way with thoroughly satisfactory results in seventy-eight. He uses the following formula:

℞.—Hydrargyri benzoatis . . . gr. v.
Sodii chloridi . . . . gr. jss.
Aquæ destillata . . . . f℥j.
Sig.: ♏xv as an injection.

As a result of his observations he has arrived at the following conclusions:

1. If the bubo display a virulent tendency, the injection does not affect its development, and suppuration occurs.

2. When decided fluctuation exists and the skin is thin and cyanotic, the injection can only hasten the disappearance of the infiltration. As a rule, the bubo must be opened.

3. If fluctuation is considerable in degree, but the skin, though red, is thick and well nourished, the chances are good that an injection into the adjacent infiltrated area will (possibly in 50 per cent. of cases) obviate the necessity of opening the bubo.

4. If there is little or no fluctuation, it is highly probable (possibly in 90 per cent. of cases) that, even though fluctuation subsequently becomes decided and a few drops of pus ooze from the site of puncture, the bubo will disappear, leaving no trace of a cicatrix.—*Monatshefte f. prakt. Dermatol.*, July 15, 1891.

Dentition and Infantile Disease.—Brothers (*Archives of Pediatrics*, August, 1891) maintains that dentition is rarely or never a cause of death. He believes that dentition may be precocious or retarded in otherwise healthy children or in families. In the majority of healthy, breast-fed infants the eruption of the first teeth begins at six and a half months and is completed at thirty months. In children brought up on a mixed or artificial diet, primary as well as secondary dentition is distinctly retarded. Congenital disease—tuberculosis, syphilis, endocarditis—seems to retard dentition. Rhachitis has a pronounced retarding influence upon dentition. Scrofulosis seems to accelerate the eruption of the first teeth, but does not affect subsequent dentition. In cases of defective cerebral development, as in idiocy, the whole process of dentition is retarded. Chronic disease retards the eruption of the first teeth, but does not influence subsequent dentition. In marantic children, primary dentition is precocious, but secondary dentition is delayed. Epileptics seem to have their first teeth early.

Cæsarean Section for a Giant Infant.—Rachel and Neumer (*Répertoire d'Obstét. et de Gynéc.*, May 25, 1891) report the case of a woman, forty years old, the abdomen of whom, in the twelfth pregnancy, was enormously distended. The labor not progressing, version was attempted, but the fetus would not pass the superior strait. Disarticulation of the leg, preparatory to evisceration, was attempted, but was unsuccessful. Finally, Cæsarean section was decided upon. The mother died soon after the extraction of the fetus. The latter, almost exsanguinated as a result of the amputation, weighed twenty-two and a half pounds. The parents were not unusually large. The only explanation of the great size of the fetus lay in the age of the mother and the number of pregnancies and in the fact that the fatal pregnancy had passed one month beyond term.—*Lyon Médical*, July 12, 1891.

Hypnotism.—In a paper read before the Colorado State Medical Society, Eskridge (*New York Medical Journal*, August 1, 1891) stated that hypnotism is real and subjective and not dependent upon any mysterious influence of the hypnotist over the subject. The therapeutic value of hypnotism is governed by the mental impressions made during hypnosis, a state of increased impressionability. Much that is accomplished by hypnotism may be accomplished by repeated impressions without hypnosis. Hypnotism carries with it certain dangers to the hypnotist, to the subject and to the community, to be obviated by proper precautions. It remains to be determined whether or not the therapeutic value of hypnotism is greater than the unavoidable dangers of its application. The practice of hypotism should be under state control and restricted to physicians and other scientific investigators.

Cerebral Syphilis.—As a result of his observations during a long experience, Tarnowsky (*Archiv f. Dermat. und Syphilis*, No. 3, 1891) excludes progressive paralysis and tabes from among the manifestations of syphilis of the nervous system. It is his view that the debilitating influence of syphilis merely prepares the way for the development of progressive paralysis and tabes in those in whom there exists a congenital predisposition to these diseases. Tarnowsky makes the further proposition that if, in cases of syphilis with nervous manifestations, tabes and progressive paralysis can be definitely excluded, 90 per cent. will be cases of cerebral syphilis, in the majority of instances susceptible of cure. —*Monatshefte f. prakt. Dermat. und Syphilis*, July 15, 1891.

Rupture of the Thoracic Duct.—EYER (*New York Med. Record*, August 1, 1891) has reported the case of a railway brakeman, who, while engaged in work, was severely squeezed. Right-sided pneumonia subsequently developed. On the seventeenth day after the injury evidences of deep-seated suppuration were apparent near the anterior superior spine of the right ilium. An incision disclosed a fistulous tract, from which emanated a discharge having a fecal odor and appearance. In the course of a few days the offensive odor disappeared. The discharge was now opaque and milky. An intestinal fistula was diagnosticated. Emaciation progressed with extreme rapidity. Thirty-eight days after the reception of the injury the patient died. At the autopsy an opening was found in the thoracic duct at the level of the diaphragm.

Removal of the Apex of the Lung for Tuberculosis (*Gazette hebd. de Sci. Méd.*).—In a case of early tuberculous disease of the apex of the right lung DR. TUFFIER has successfully resorted to operative measures. The means adopted, based upon experiments made upon a dog, consisted in a simple incision through the second intercostal space anteriorly. Afterward the parietal pleura was divided, which induced a kind of sub-pleural pneumothorax; the apex of the lung became reduced in bulk sufficiently to be easily drawn through the wound; it was then cut away by the écraseur, and the stump sutured to the intercostal incision to prevent retraction of the lung. Dr. Tuffier exhibited the patient, who had progressed very favorably after the operation.—*Provincial Medical Journal*, July 1, 1891.

Chylous Ascites.—VALI (*Wiener med. Presse*, July 12, 1891) presented to the Royal Society of Physicians, at Budapest, a woman fifty-eight years old, who, following an attack of fever a year previously, had complained of pain in the hepatic and inguinal regions. Several months later, enlargement of the abdomen was observed. On puncture for the third time, after the lapse of varying intervals, three gallons of a yellowish-white, translucent, milky fluid, oily to the touch, was evacuated, on the surface of which, after standing, a creamy layer formed. The subjacent fluid was alkaline, of a specific gravity of 1013.3, and made up of 964.8 parts of water and 35.2 of solids (including albumin, fat, salts, peptone, sugar, and urea). Microscopically, the granular sediment was found to contain fat-globules, lymph-cells, and blood-cells.

Post-apoplectic Hemianopsia.—LEYDEN (*Wiener med. Presse*, July 12, 1891) reported to the Society for Internal Medicine, at Berlin, the case of a woman sixty-nine years old, with left hemiplegia, left ptosis, and conjugate deviation of the eyes and head to the right, who, for three days presented the hemianoptic pupillary reaction or immobility. The pupil contracted on illumination of the intact half of the retina, but not on illumination of the anesthetic half. Wernicke has demonstrated that this peculiarity depends upon a lesion interrupting the pupillary reflex arc in front of the corpora quadrigemina. When the lesion and consequent reflex interruption are behind the corpora, the pupils react. In the case in question, the autopsy confirmed the accuracy of the observation—a lesion was found in the quadrigeminal region.

The Elimination of Micro-organisms in the Sweat.—In a case of chronic pyemia, BRUNNER (*Berliner klin. Wochenschr.*, No. 21, 1891) found the staphylococcus pyogenes albus in the blood; and after the administration of diaphoretics, he was able to demonstrate the presence of the same organism in the sweat. Stimulated to further investigation, he inoculated a young pig with cultures of the staphylococcus aureus, a cat with anthrax bacilli, and another pig with the micrococcus prodigiosus. In each case Brunner was able to demonstrate the presence of the respective organism in the sweat, and in the last, in the saliva as well.

The Etiology of Erysipelas.—As a result of his observations, and from a study of the literature of the subject, JORDAN (*Archiv für Chirurgie*, 42, ii., 1891) has concluded that erysipelas is etiologically not a specific disease; as a rule, it is caused by the streptococcus pyogenes, but it may also be caused by the staphylococcus pyogenes. The etiological agent probably finds its way into the blood in every case. In this way metastases may result: the pyemia of erysipelas is thus primary—dependent upon the erysipelas coccus. The variability of action of the pyogenic cocci depends upon their localization and variations in their virulence—thus quantitative.

The Conservation of Living Malarial Parasites.—Failing in his efforts to cultivate the parasites of malaria in artificial culture-media, ROSENBACH (*Berlin klin. Wochenschr.*, August 24, 1891) endeavored to reproduce the natural conditions of life of the organisms. To accomplish his purpose he used leeches, which he applied in the splenic region in cases of malaria, and found that by opening the leeches at the end of forty-eight hours the apparently normal blood containing parasites could be obtained. It even appeared that in the interim the parasites underwent some changes of development.

Idiocy and Hermaphroditism.—MORAVCSIK (*Wiener med. Presse*, July 12, 1891) presented to the Royal Society of Physicians, at Budapest, a well-developed child eleven years old, of doubtful sex, with a head smaller in all dimensions in proportion to the size of the body, and an especially narrow forehead, and with a well-developed penis at the upper angle of the labia. The child had been educated as a girl. Its voice and manner were rather those of a boy. Its mental development was slight. Writing was done with the left hand and from right to left.

Inhalation of Oxygen in the Cyanosis of the Newly Born (*Bulletin Obstétricale*).—After resorting to various measures for the relief of cyanosis, DR. BONNAIRE adopted the plan of conveying through a tube a current of oxygen to mix with the atmosphere surrounding the child. The general condition improved rapidly under this plan of treatment. The remedy appears to combat the secondary conditions of respiratory weakness and general asthenia. Artificial warmth is a necessary condition for the administration of oxygen to be successful.—*Provincial Medical Journal*, July 1, 1891.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

PHILADELPHIA.

SATURDAY, SEPTEMBER 19, 1891.

THE TREATMENT OF INFECTIOUS DISEASES.

THE richest fruits of the science of bacteriology are yet to be realized. We have already learned much in the way of rational prophylaxis, but there is much more to be learned, both as to the prevention and the cure of disease. It would be folly, however, with the unravelling of the many knotty problems in the causation of disease, to anticipate either a therapeutic revolution or revelation. On the contrary, it is probable that many current methods of treatment (empirical though they may be) will be shown to be useful in virtue of their bactericidal activity. In illustration, we need but advert to the use of mercury in syphilis, and of quinine in malarial fevers, and we have no more perfect types of specific therapeutic measures than these drugs. Though the one disease is not yet generally admitted to be dependent upon a bacterium, the evidence is conclusive that the other is a result of the presence of a parasite in the blood. Our new knowledge, however, does not alter our therapeutics. If syphilis is a microbic disease, it can occasion no surprise that such a powerful microbicide as mercury should be an effective therapeutic agent in syphilis. It is known that quinine inhibits the corpuscular activity of the blood and that it is antiseptic. With the parasitic nature of malarial diseases established, the usefulness of quinine in these diseases needs no further explanation. At this juncture we are confronted with the fact that germicidal remedies cannot be interchangeably applied in the treatment of germ-diseases. In other words, a remedy of especial utility in one condition may be quite nugatory in another. Thus mercury has no curative effect in malarial disease, quinine none in syphilis. It will still be necessary to determine, perhaps empirically, the special agent suitable for the individual disease, as well as the precise mode of action in the cure of each case.

What has already been said will let us now take up for consideration the *rationale* of the treatment of erysipelas. The most popular remedy in the treatment of erysipelas is perhaps iron and quinine in combination, of which it must be admitted that it is reliable and efficacious. Another remedy is pilocarpine, injected subcutaneously, which acts with almost specific promptness and efficacy. A third remedy to which we shall refer is the cyanide of mercury, which, injected subcutaneously, close to the seat of disease, has in the hands of some given gratifying results. The mode of action of quinine and iron, and of the cyanide of mercury, needs no further elaboration.

We know that physiologically pilocarpine is a powerful diaphoretic. This property depends not only upon the cutaneous hyperemia developed, but also upon a special influence upon the secretory apparatus. As a result of both of these conditions, the skin and subcutaneous tissues are flushed with blood and excessive exudation. The vital activity of the streptococcus of FEHLEISEN is heightened. Living faster, it dies faster. The increased production of the excrementitious products of bacterial activity causes the speedy death of the organism and the cessation of the disease. Add to this the fact, now demonstrated beyond cavil, that bacteria are eliminated in the perspiration, as well as in the saliva and in the urine, and we require no more to make clear the usefulness of pilocarpine in erysipelas, though it is not impossible that the antiseptic qualities of the body-fluids, with which the tissues are deluged, play some part in the limitation of the disease.

In this connection another fact presents itself. The intimate relation between erysipelas and parenchymatous nephritis is well recognized. Not only

does nephritis appear as a common complication of erysipelas, but those with nephritis show a special predisposition to the development of erysipelas. That there should be an infectious nephritis (microbic or toxic) in association with erysipelas may be readily understood, while it may readily be conceived that the defective elimination of excrementitious products on the part of a kidney damaged by disease will throw additional work on the cutaneous excretory apparatus, with a diminution of resistance or the establishment of conditions favorable to the invasion and propagation of the streptococcus.

COMMERCIAL ENTERPRISE AND PROGRESS IN THERAPEUTICS.

THE enterprising spirit of the modern drug trade has had many good results, some evil ones. Even to its good results there is a sad side; and the observant student of cotemporaneous medical history must at times entertain grave apprehensions as to the future of therapeutic science among the rank and file of American physicians. Let us look at one or two striking facts. More than thirty years ago, BENJAMIN WARD RICHARDSON introduced hydrogen dioxide as a therapeutic agent, and during the intervening years he has at intervals worked out and published its manifold uses. Other reliable writers made occasional report of the action of the drug, or enumerated it in lists of agents applicable in certain conditions. It attained, however, in America at least, but a limited repute and employment. Within a few years—less than a decade—a manufacturing chemist has largely advertised in the reading and other columns of medical journals and by means of circulars, the peculiar virtues of his brand of the drug. Immediately we find a host of writers springing up to quote from one another the statements of this manufacturer and the excellence of his product. Out of a dozen or two of these, one may vaguely refer to RICHARDSON, but none seems to be at all aware of the thorough character of that author's researches; and some propose as novel, expedients that he has long since tried and either approved or rejected.

The obvious state of affairs is that the little knowledge these writers have, comes from the circulars of the manufacturer and not from the teachings of the physician.

Very recently a manufacturing firm has prepared and circulated very extensively a secret mixture of coal-tar products, under a name fashionably beginning with *Anti*. Nobody knows anything about this powder except what the manufacturers tell him. But we find some apparently reputable physicians rushing into print to extol its superlative virtues in every imaginable and unimaginable painful or febrile affection; and many others must be experimenting with it upon the lives of their patients, or the manufacturers would not find it pay to distribute their pharmaceutical and literary products so extensively as they are doing.

Thus we see one of the most useful of therapeutic agents, introduced after careful and thorough investigation by a leader of medical thought, practically ignored until fathered by a manufacturer; and then adopted not through the reports of the scientific investigator, but through the commercial enterprise of the manufacturer. On the other hand, we see an unknown, possibly dangerous and probably worthless, mixture, extensively used without any preliminary scientific investigation or reliable clinical report, simply and solely on the merits of its advertising.

"THE PEOPLE'S BATH."

IF it be a pleasure to give pleasure to others, how great must be that of the New York gentleman who sent $200 to be used in supplying free baths to the unwashed boys of New York. He gave 4000 boys an opportunity that they greedily seized upon of getting an excellent and decent washing. And when one considers that the good indirectly done by these baths is far greater than the pleasure, the originator of this movement must feel that he has certainly accomplished a great reform and work in the world. DR. BARUCH would be a little more than human if he were not elated at this practical demonstration that all "hobbies" are not "mere theories," and that the "cold-water hobby" is one that well ridden will do great good to a whole community. He has made it possible for a New York working-man or boy to have the best kind of a bath, cold or warm, with pure water, in a private room, with a new cake of soap and a clean towel—"all for five cents, and if the five cents is hard to find, the bath may be had scot-free."

Such things as this are bright compensations for many of the evils of civilization. Every city awaits a duplication of this noble charity, and each of us should try to bring it about.

SOCIETY PROCEEDINGS.

SEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

Held at London, August 10 to 17, 1891.

(Continued from p. 310.)

In the Section of Preventive Medicine, Dr. Edward Ballard considered the subject of "Meat Inspection and Food Poisons." He reported twelve instances of poisoning by articles of food. The symptoms were those due to a virulent chemical poison produced by a microörganism either in the food or in the body of the recipient of the food. The precautionary measures recommended were:

1. Thorough cooking of such prepared foods as ham or bacon. 2. Scrupulous cleanliness and ventilation of places where the food was stored or where pork was salted and dried. 3. The adoption of precautions to prevent the rise into such places of ground-air or the entry of other morbific and unwholesome emanations.

Dr. Victor Vaughan quoted cases from his experience similar to those described by Dr. Ballard, and emphasized the importance of the work that those who were called upon to investigate food-poisoning must do. The method of procedure must be both chemical and bacteriological. A careful and thorough search for inorganic poisons should be made. The germs found should be grown under conditions as nearly identical as those under which the suspected food had existed as could be obtained. Tests should be made, not only for the basic products of putrefaction, but for the bacterial proteids as well. Physiological tests upon lower animals should never be neglected.

Dr. Arthur Ransome, F.R.S., read a paper on "The Need for Special Measures for the Prevention of Consumption." That the disease was curable was proved by the facts that (1) the post-mortem examinations of persons dying from other diseases afforded unmistakable evidence in from 25 to 50 per cent. of spontaneous cure of tuberculous disease; (2) by the testimony of many physicians, among whom the speaker was one; he had satisfied himself that in the large majority of cases a fatal issue was brought about not by one or two, but by repeated invasions of the bacillus from an unhealthy environment. That the disease was preventable was shown in (1) the statistics of the British army, in which the mortality from lung-disease had been reduced to one-third or one-tenth of the former rates by attention to drainage and ventilation of barracks; and (2) by the statistical researches of Dr. Buchanan, who had shown that in certain English towns the mortality had been reduced by drainage; and (3) by the reduction in the general phthisis rate from 2.5 to 1.5 per mille since the passing of the Public Health Acts. Since phthisis was curable, and since it was known that many persons did recover from it, the number of susceptible persons must be very large, and the necessity for preventive measures the greater. Tuberculosis was communicated occasionally by direct personal intercourse, more frequently by the milk or flesh of tuberculous cattle, by the inhalation of tuberculous dust, and by residence in an infected house or urban area. As preventive measures he advocated (1) notification of cases; (2) disinfection of fomites, spittoons, and houses; (3) provision of ample hospital accommodation (by the local authorities) for patients too ill to work; (4) general sanitary measures, including ventilation, drainage, and reconstruction of unhealthy areas.

Sir Dyce Duckworth opened the discussion on "The Relation of Alcoholism to Public Health, and the Methods to be Adopted for its Prevention." He stated that the opinion of the medical profession was that no harm appeared to ensue from alcohol when used legitimately—that is, in small quantities and with meals. Bad (impure) alcohol was harmful. For the careless drunkard stern measures ought to be employed, such as cumulative fines, deprivation of electoral franchise, and corporal punishment. Hopeless cases were those with an ancestry that had abused the use of alcoholic drinks.

Professor Harald Westergaard stated that the effect of alcoholism on public health depends not only on the average quantity consumed, but on the distribution of this quantity. In several countries an enormous part of the divorces bear some relation to the abuse of strong liquors. The inmates of poor-houses and lunatic asylums very often are the victims of intoxicating drinks. The large number of police offences and crimes caused by alcoholic excess will show to what an extent in many countries alcoholism claims the attention of the public. He also considered the influence of alcoholism on the mortality-rate, and made reference to the legislation for the suppression of the abuse.

Dr. Norman Kerr said that the evil of intemperance could be remedied (1) By recognizing inebriety as a disease, and drunkenness as very often but an effect or symptom of disease. In the Dalrymple Home, though the previous average term of alcohol-addiction had been nine years, more than one-third of the cases had afterward done well. Penal discipline had been a failure. (2) By amended legislation to provide for (*a*) the compulsory reception and retention of inebriates too demoralized to apply of their own accord; (*b*) the reception of voluntary applicants on a simple agreement, without appearance before justices; (*c*) the care and treatment of the poor and of those of limited means. It would be well also for guardians to have power to pay for the care and treatment of pauper inebriates, and for the authorities to establish special hospitals for the detention and treatment of inebriates convicted of crime. Immunity from the physical, mental, moral, and social ravages wrought by alcoholism could be eventually secured only by general abstention from even the "limited" use of intoxicants; their exclusion from social, political, and sacred functions; and the scheduling of alcoholic beverages as a poison under the Pharmacy Acts, or, by some other legislative enactment, the prohibition of their manufacture and common sale.

Dr. Isambard Owen stated that the conclusions appended to the "Collective Investigation Report on Intemperance" of the British Medical Association clearly stated that habitual indulgence in alcoholic liquors had a distinct tendency to shorten life.

Dr. Richard Sisley read a paper on "The Prevention of the Spread of Epidemic Influenza." He contended that influenza spread along the lines of human intercourse, and was not, always at least, wind-borne.

Attention to general hygienic measures rendered the spread of the disease less rapid; quinine was not a certain prophylactic, but there was some evidence in favor of the prophylactic value of the application of a solution of boric acid to the conjunctivæ. The main point to be attended to was the avoidance of infection during an epidemic. He advocated special care to prevent the introduction of the disease into large public institutions in which it was apt to spread rapidly, the closure of elementary schools, and the disinfection of letters and parcels, in addition to personal precautions.

DR. ROBERT W. FELKIN considered "Malaria, Enteric Fever, and Phthisis." He discussed the various reasons for holding that malaria was a definite disease due to the same cause under whatever guise it appeared. He did not believe that typho-malarial fever existed as a separate disease. Black-water fever was, in his opinion, a severe form of malarial fever, and not a definite, distinct disease. There seemed to be a certain antagonism between malaria and phthisis, for wherever malarial fevers were most rife in Central Africa he had never seen a case of phthisis, which was only met with, so far as he was aware, in localities where malaria rarely occurred—namely, at high altitudes.

DR. PROSPERO SONSINO read a paper on "The Most Efficacious Means of Preventing the Spread of Entozoal Diseases in Man." The most important prophylactic measures were those to be taken by the individual. Pure water, cleanliness in the keeping and cooking of food, and personal cleanliness, were points dwelt upon. He insisted on the need of care in making use of special forms of food used by the natives of countries possessing special entozoa. His observations had led him to the conclusion that in hot climates three forms of entozoa—anchylostoma duodenale, filaria sanguinis hominis, and Bilharzia hematobia—were important factors in the production of disease and mortality.

In the Section of Bacteriology, DR. J. BURDON SANDERSON opened the discussion on "Tuberculosis." He formulated the following propositions:

There is no sufficient reason for supposing that in the human adult the introduction of the bacilli of tubercle by enteric absorption is the efficient cause of tuberculosis. In infancy a large proportion of the apparently idiopathic tuberculous diseases of the lymphatic system are probably due to the penetration of bacilli into the organism from the intestine; but the evidence that we at present possess on this subject is not sufficiently precise or extended to serve as a basis for prophylactic action. For this reason the origin of tuberculosis in infancy is a subject that urgently requires investigation.

It has been proved that the ingestion of any material which contains the bacilli of tubercle is a source of risk to the consumer, but the conditions that limit this risk are insufficiently known. It would, therefore, be unjust to enforce the destruction of any specimen of meat apparently healthy, even though it were known to be derived from a tuberculous animal, excepting on evidence given by an expert as regards the particular case that it would be infecting if administered to test-animals.

As regards the duty of the State in relation to the prevention of tuberculosis, what is immediately required is, first, that tuberculosis should be added to the list of diseases regarded by the law as contagious; and, secondly, that an efficient system of skilled inspection should be created. This is desirable, not merely as a first step toward prevention of the sale and consumption of tuberculous meat, but as an indispensable means of acquiring better information than now exists. To be of use it must be conducted by men of technical skill under scientific guidance.

In conclusion, Dr. Sanderson expressed the belief that the consumption of unboiled milk during the years that follow weaning must have its share in bringing about the fatal prevalence of tuberculous disease at that period of life. He held that the sale of contaminated milk ought to be stopped by all possible means.

DR. B. BANG read a paper on "The Alleged Danger of Consuming the Apparently Healthy Meat and Milk of Tuberculous Animals." He maintained that from an economic point of view it was scarcely feasible to interdict the use of milk and meat from tuberculous animals. Milk ought always to be boiled. Difficulty is encountered in the preparation of products derived from milk, such as cheese and butter. To overcome this, the milk is first exposed to a heat of from 140° to 164° F., by which tubercle bacilli possibly present are sufficiently attenuated to be incapable of infecting the alimentary canal. As, however, many people object to the taste of boiled milk, it becomes an important question to determine whether the milk of phthisical cows is really a source of danger in the majority of cases. Dr. Bang has determined that when the udder is affected with tuberculosis there are usually numerous bacilli in the milk, which is consequently extremely dangerous. But he also finds that mammary tuberculosis is not so common as was at one time supposed. He maintains that although in many cases the milk from phthisical cows is not virulent when the mammary gland is unaffected, it is in a certain proportion of cases, and should always be looked upon with suspicion, and it is absolutely necessary to take prophylactic measures against the use of such milk. With regard to meat, flesh itself very seldom contains any tubercle. Nevertheless it has been proved by a number of experiments that muscle-juice may contain tubercle bacilli. The eating of uncooked meat should be discouraged; but the best means of avoiding danger to the health of man is to take all possible measures for preventing the propagation of tuberculosis among domestic animals.

PROFESSOR ARLOING held that, with few exceptions, the total condemnation of tuberculous meat was necessary. The flesh of tuberculous animals should be suspected as dangerous to health, especially as meat is often undercooked, the bacilli remaining pathogenic.

PROFESSOR MACFADYEAN and DR. WOODHEAD read a paper on "The Transmission of Tuberculosis to Man by Means of Flesh and Milk Derived from Tuberculous Animals." They held that intestinal and mesenteric tuberculosis was most common in children shortly after weaning, when cows' milk was substituted for mothers' milk. In these cases the point of entrance was probably by the intestines. They had concluded that in some cases at least the tubercle bacilli had passed from the intestine into the mesenteric glands, without leaving any trace of lesion to indicate the point of entrance. Tubercle bacilli are undoubtedly sometimes present in the milk from

tuberculous cattle, especially when the udder is affected. They held that it is not less than criminal to give such milk to delicate children or to children with intestinal catarrh.

DR. METSCHNIKOFF and DR. ROUX presented a joint paper on "The Changes that Take Place Around the Tissues of Tubercle Bacilli." They stated that the process of recovery consisted in the development of concentric layers of dense inflammatory tissue around the bacilli, which eventually led to their absorption, the inflammatory tissue itself finally undergoing a process of calcification.

PROFESSOR EHRLICH gave Koch's views regarding tuberculin. He stated that the results obtained were exceedingly favorable, and that in most of the cases in which he had failed to obtain equally good results it was because he had used too large doses of tuberculin. The principle of cure rested on the local effects that tuberculin exercised on the specifically affected tissues; and the violent inflammatory reaction, passing to necrosis, was neither desirable nor necessary; but, on the contrary, slight and often rapid stimuli would give rise to cicatrization of the tuberculous centers, so that the essence of this method of treatment was to retain as long as possible the specific excitation of the tissues, and not to do away with these, as was the case if large doses were used. Successful results have been obtained by the use of repeated minute doses of tuberculin that were only very gradually increased. It should be specially noted that the pathological signs found as the result of the action of tuberculin were always produced by large doses.

DR. BEHRING read a paper on "Disinfection in the Living Body." He stated that there are four possible ways in which it is conceivable that disinfection within the body may be effected: 1. By killing the disease-producing germs. 2. By hindering their growth. 3. By counteracting their disease-producing properties—pathogenic organisms losing their power to produce poisonous products. 4. By antagonizing the action of or destroying altogether the various toxic products originated by the bacteria.

He detailed the method of conferring upon animals immunity from diphtheria. He held that the curative power of the blood was not dependent upon its living elements, or, at least, is not limited to these. It is rather to be traced to the circumstance that the extravascular blood and the blood-serum of immune animals possess the property of destroying specific poisons without destroying the bacilli. He concluded by stating that perhaps in the general treatment of infectious diseases the same principle may be found to apply as Lister has with such good results applied in the local treatment of infectious wounds—namely, to remove or to render harmless the various causes of disease while leaving the living cells of the tissue in place.

The PRESIDENT (SIR JOSEPH LISTER) said that the phagocyte naturally existed where it could obtain nourishment, and therefore something besides chemical action must be looked for, as there was a great difference between living and dead tissues.

In the Section of the Relations of the Diseases of Animals to those of Man, DR. OSTERTAG discussed "Milk Diseases and the Regulation of Milk Supply." He insisted that the State should see that only pure milk entered the market. The following kinds of milk ought to be excluded: (1) Milk which, without being necessarily prejudicial to health, was peculiar in color, taste, or consistence (nauseous milk); (2) all milk that was prejudicial to health, or which was suspected on good grounds of being so. The milk of animals that had been fed on poisonous fodder, or that have been treated with certain medicaments, and of those suffering from tuberculosis, malignant pustule, cow-pox, aphthæ, or general illness in consequence of some process inducing ulceration, must be regarded as prejudicial to health. In order to guard against these dangers it was requisite (1) that all dairy farms be licensed; (2) that all animals kept for milking be examined by a veterinary surgeon from time to time; (3) that the owners of dairy farms be bound to provide only good undamaged fodder, and to give immediate notice of the illness of any milch cow to the attending veterinary surgeon, and, until he gave leave, not to send the milk of the diseased animal to market; (4) that the business of milking be performed with the most punctilious cleanliness, and that no person suffering from any infectious illness be employed to milk; (5) that the mixed milk obtained by milking be cooled and stored in special rooms, not in living or sleeping-rooms; (6) that it be transported only in suitable vessels; (7) that during the prevalence of aphthæ only boiled milk should be brought into the market, whilst all milk which must be considered nauseous or injurious should be excluded from the provision market; at the outbreak of any epidemic in a house in which dairy farming was carried on, the sale of milk should be forbidden; (8) in obtaining the so-called "milk for children," especially strict regulations ought to be carried out as to the feeding of the milch cows, cleanliness in milking, and the cooling and proper mode of transport of the milk.

PROFESSOR BROWN pointed out that milk was more frequently contaminated by the hands of the milkers and the excreta from the cows than by disease-producing germs, and he gave a short account of the number of different microörganisms which he had detected in milk collected in the most careful manner from healthy cows.

MR. FRANCIS VACHER read a paper on "The Inspection of Meat with Regard to the Prevention of Disease." He proposed: 1. The general provision of public abattoirs. 2. Closing of private slaughter-houses. 3. Licensing and registering of all butchers and their premises. 4. Appointment of competent inspectors of meat. 5. General systematic inspection of animals and meat intended for food. 6. Appointment of competent assessors to sit with magistrates and assist them when necessary in the hearing of cases relating to diseased meat.

DR. W. MARCET read a paper on "The Effects of the Respiration of Carbonic Acid on Man." His conclusions were as follows: 1. That when air containing an excess of CO_2 is breathed, the gas accumulates rapidly in the blood, and under such a condition the phenomenon of nutrition is more or less interfered with, and also that people working in ill-ventilated rooms and buildings should, toward the preservation of their health, sleep in as pure an atmosphere as possible, where they will rid their blood of the carbonic acid absorbed in the daytime. 2. That the effects produced by inhalation of carbonic acid gas depend greatly on the rapidity of the exposure. The sudden inhalation of air containing a

large proportion of the gas may produce rapid insensibility and death, while this same air might have been breathed for some time with a certain degree of impunity had the carbonic acid present been increased gradually. 3. That when life is threatened by the inhalation of carbonic acid there is no reason to despair of artificial respiration so long as the heart is beating; the gas will diffuse rapidly from the blood into the air with which the lungs are inflated, and thus be carried out of the body.

SIR ARTHUR MITCHELL and DR. BUCHAN read a paper on "Influenza and Weather of London." They found a winter maximum of mortality and a summer minimum. During epidemics, deaths from influenza accounted for only about one-seventh of the increase in the mortality. The increase was due to the increased number of deaths from bronchitis, pneumonia and phthisis, diseases of the circulatory system, and enteritis. The heaviest contribution to the death-rate was made by diseases of the respiratory apparatus, though the temperature was high and there were no fogs—evidence that something of an exceptional character was operating to increase the number of deaths from diseases of the respiratory organs.

DR. V. LOGIE read a paper on "The Prophylaxis of Pulmonary Tuberculosis and the Mortality from Phthisis in the Belgian Army." He contended that all men who appeared weak in constitution should be excluded from the army. The effect of crowding, which was the inevitable characteristic of the soldier's habitation, should be neutralized as much as possible. In the future there would have to be separate day and night premises, all access to bedrooms being forbidden after a certain hour —fixed as early as possible—and the rooms thoroughly ventilated until the evening recall. A prize should be given for cleanliness of body, clothes, and room. Clothing should be adapted to the season, so as to diminish the risk of taking cold. The food should be improved and more varied. All administrative formalities should be fulfilled as rapidly as possible, so as to leave in barracks as short a time as possible all men proposed as pensioners on account of consumption, and to isolate them meanwhile more than is done. The medical officer should give special attention to men who seem to have been getting pale and thin for some time. The men should be made to understand as much as possible that if military life strengthens and invigorates the body, it also makes it liable to different diseases, and particularly to consumption, to escape which they must avoid all excess, uncleanliness, etc. The ravages committed in armies by consumption should be made as well known as possible to those whom it concerns..

In the Section of State Hygiene, SIR HENRY THOMPSON inaugurated the discussion on the subject of "The Disposal of the Dead." He said that infectious diseases were highly communicable after as well as before death. Destruction by fire was the only perfect and absolute means of immediate disinfection, of avoiding the contamination of water-supplies, and of preserving the best areas for habitation or the production of food. When cremation could not be performed he urged the burial of persons dying of infectious diseases in capacious coffins filled with quick-lime.

MR. F. SEYMOUR HAYDEN followed with a paper in which he said coffins of any kind were worse than useless, but if employed at all should be of wicker or of the most perishable materials. But cremation he would denounce in the strongest terms as "a direct and potent incentive to crime."

A resolution in favor of cremation as a rational proceeding, especially called for in cases of contagious disease, was carried, with only four dissentients.

In the Section of Demography DR. FELKIN opened the discussion on "The Suitability of Tropical Highlands for European Settlement." He divided the tropics into three vertical zones of climate, each of which had its own peculiarity with regard to the presence or absence of disease. For the permanent residence of Europeans in the tropics a comparatively high altitude was requisite. In the upper or cold zone of the tropics there was a tendency to plethora, and the disorders were of an inflammatory character. Diseases of the respiratory and circulatory organs were relatively common, whilst malaria, yellow fever, cholera, phthisis, dysentery, and hepatitis were almost entirely absent. In the middle zone the seasons exerted an influence, and consequently the presence and prevalence of disease fluctuated. As a whole, however, diseases in this region (having a mean annual temperature of from 41° to 73° F.) were less virulent in character. The lowest or hot zone was the typical tropical disease zone, and here anemia, malaria, diseases of the gastro-intestinal tract, hepatitis, dysentery, diarrhea, beri-beri, dengue, and yellow fever were met with. Typhus fever, plague, goiter, cretinism, and for the most part diseases of the kidneys, were not met with. It was found that an altitude of from six to ten thousand feet was necessary for the British people and North Germans to reside permanently in such districts, and even there the areas for colonization must be carefully selected, and all sanitary precautions taken. Although altitude might give an invigorating climate, there must always be certain elements detracting from its value, namely, the powerful sun, the rarefied air, and the absence of a well-marked summer and winter.

DR. KÖRÖSI read a paper on the "Influence of Parental Age on the Vitality of Children," in which he said that girls should not be married before the age of twenty. The most vigorous children issued from fathers of from thirty to forty years of age, the children of younger and older fathers dying somewhat oftener through uterine causes. It was curious, however, that when the fathers were advanced in life—about sixty years of age or more—the vitality of children seemed to increase anew. As to the influence of the combined age of parents, the results went to prove that old men ought not to marry young women.

MR. F. GALTON read a paper on the subject of "Finger-prints as a Means of Personal Identification," showing the degree of facility by which it was possible to determine whether the duplicate of a submitted set of impressions was or was not contained in a catalogued collection of the finger-prints of different persons, say of criminals. The prints used were those of the bulbs of the ten digits, and in each there were on the average at least twenty distinct points of reference, so that a degree of certainty in identification far exceeding that by any other method could rapidly be obtained.

At the conclusion of the Congress, the degree of Doc-

tor of Laws was conferred by the University of Cambridge upon Professor Brouardel, of France; Professor Conradi, of Italy, and Professor von Fodór, of Hungary.

It was decided to hold the next Congress in 1894 at Budapesth.

SECOND CONGRESS OF TUBERCULOSIS.

Held in Paris from July 27 to August 2, 1891.

(Continued from p. 281.)

DR. CH. LEROUX, of Paris, presented a communication on the "Therapeutic Results Obtained in the Treatment of Tuberculosis in Sanitariums and Hospitals." Of 4692 patients treated from 1869 to 1882, at the Marine Hospital for tuberculous patients, the proportion of cures has been 70.7 per cent. At Banyuls, of 146 patients there were 118 cures, 12 ameliorated, and 6 deaths. At Cannes, of 51 cases of scrofulo-tuberculosis treated in six seasons there were 38 cures, 6 ameliorations, and 2 deaths; in 2 the condition remained stationary. Leroux believes that the result is in direct relation to the length of time spent at the sea-shore. All tuberculous patients cannot adopt the sea-shore treatment. For scrofulo-tuberculosis, the sea-shore treatment is necessary, and Leroux even thinks that it would be desirable to send all debilitated or predisposed subjects to the sea-shore, without waiting for the disease to manifest itself. The contra-indications are painful tuberculosis, aggravated Pott's disease, and lupus, while an absolute contra-indication is pulmonary or visceral tuberculosis.

DR. VIDAL, of Hyères, maintained that short treatments are preferable to long treatments, for after a while a child ceases to derive any benefit from a stay at the sea-shore; he prefers to have them go often and stay but a short time.

DR. DUBRANDY, of Hyères, highly recommended nocturnal ventilation of the patient's room, as an important factor in the treatment of tuberculosis; any system that will permit the entrance of fresh air into the room is a good one, but the currents of air should always be broken by the shutters, which should be closed; small openings left at the upper and lower parts of the window are sufficient for good ventilation. Curtains may be drawn over the windows while these are partially opened; this will avoid draughts.

When there is a strong wind, storm, or much rain, the windows should be tightly closed. When the windows are opened the temperature of the room remains almost unchanged; the variations in the external temperature do not materially influence the temperature of the room, because depression of temperature is compensated for by heat-radiation from the walls, furniture, the temperature of the patient, and above all the temperature of the expired air. 11° C. (51.8° F.) is a safe temperature to be maintained in the sick-room during the winter, and this can readily be accomplished by a small fire.

DR. SABOURIN, of Vernet les Bains, stated that he found that nine-tenths of phthisical patients do much better on dry and cold winter days than during mild weather; at Vernet les Bains patients are all placed in a veranda having a large number of windows, and provided with sofas and woollen covers, with hot bottles for their feet and woollen coverings for their shoulders; but they are not exposed to the rays of the sun. On returning to their rooms the windows, which have been opened all day, are kept partially opened; this mode of life is followed for from three to six months; the treatment has been carried on even when the temperature fell to —6° and —7° C. (19–21° F.). Under such treatment the appetite returns and all the other symptoms are reduced to a minimum.

DR. POIRIER presented a communication on the "Incision of Pulmonary Cavities."

The more recent collected operations of this kind include 29 incisions of tuberculous cavities with excision of ribs, followed in 15 cases by amelioration, in 4 by cure, and in 9 by negative results, and in 1 by an unknown result. The steps in the operation are: With the thermo-cautery make an incision 4 cm. below the sterno-costal notch, 9 cm. long from mid-sternum outward, and parallel with the first intercostal space. Reaching the pleura, if no adhesions are present it is better to wait than to go any further, but if there be a tuberculous pulmonary cavity, adhesions are always present, and through these adhesions, after having incised the pulmonary tissue, it is easy to reach the cavities. As the tuberculous cavities almost always occupy the upper part of the lung, by opening through the first intercostal space the operator finds himself on a level below the cavity; to reach the latter his incision must be carried from below upward and from before backward. To reach cavities in the posterior part of the lung a similar method can be used: the spinal process of the seventh cervical vertebra must be found, and from this point an incision is made along the scapula, the trapezius and rhomboid muscles being cut through, and the first intercostal space reached; though this is much smaller than in front, excision of a rib is not to be recommended, since anteriorly it is quite unnecessary.

PROFESSOR BABES presented a communication on "The Action of Certain Chemical Substances Produced by the Tubercle Bacillus." He conducted his researches on the same lines as those followed by Koch; he endeavored to isolate vaccinal substances by precipitating filtered cultures with alcohol. The precipitates, however, contain many foreign substances, such as albumose derived from the culture-medium. Babes observed a close analogy between bird-tuberculosis and human tuberculosis. Cornil and Babes have considered bird-tuberculosis as not pathogenic in man; for this reason they have employed the bacillus of bird-tuberculosis as a point of departure for their researches. A concentrated glycerin extract or an alcoholic precipitate of cultures of this microbe have the same thermogenic action in guinea-pigs and rabbits as does tuberculin. As to tuberculin, they have found that precipitation with alcohol lowers the thermic and toxic action, which lowering is still more pronounced if the alcoholic precipitate be extracted with chloroform and ether. In this manner, as indicated by Klebs, one obtains for human tuberculosis a substance that is not dangerous, even in large doses; while, on the contrary, the substance soluble in chloroform is often extremely toxic, and even in small doses may kill inoculated guinea-pigs. On the other hand, hens and pigeons are resistant to large quantities of the remedy without a constant rise of temperature.

Of twenty-six hens inoculated with tuberculin, two presented acute bird-tuberculosis.

PROF. CHANTEMESSE, of Paris, and DR. LE DENTU presented an interesting communication on "Spontaneous Tuberculosis in the Dog." They demonstrated anatomical specimens from dogs showing in the liver and kidney lardaceous white masses of the volume of a hazel-nut having all the appearance of sarcomatous and carcinomatous tumors. Inoculations from these masses to dogs and guinea-pigs produced ordinary tuberculosis from a histological point of view. The masses consisted of an agglomeration of living and non-caseous embryonic cells, containing a large number of tubercle bacilli. This observation indicates that the dog does not possess a serum that confers immunity against tuberculosis, and that even outside of laboratory experiments the dog may contract the disease spontaneously, the lesion escaping identification on account of its resemblance to sarcoma and carcinoma.

DR. LELOIR presented a paper on "Experimental Inoculation of Lupus Vulgaris." Two hundred subcutaneous inoculations were made with negative results in guinea-pigs and rabbits. To obtain positive results in the rabbit, it is necessary to make inoculations into the anterior chamber of the eye, while in the guinea-pig it is necessary to make the inoculations into the peritoneal cavity. The result is an unmistakable tuberculosis, which, as it does not develop from subcutaneous inoculation, is not very virulent. This constitutes an important difference between lupus and ordinary tuberculosis, for in the latter, inoculation always gives rise to general tuberculosis. The small number of bacilli found in the lesion of lupus is related to the feeble virulence.

PROF. NOCARD stated that in scrofulosis the diseased tissues contain very few bacilli. Only after its transmission several times from the guinea-pig to the rabbit does the virus become more virulent, so as to be destructive of those animals.

PROF. ARLOING, who has made an especial study of surgical tuberculosis, has found a difference in the results obtained by subcutaneous injections of material from cases of surgical and cases of visceral tuberculosis. He questions differences of quantity, suggesting variations of quality. He believes that there are several varieties of surgical tuberculosis.

PROF. VERNEUIL held that the differences observed in inoculating tuberculous products can be attributed to the quantity of microbes or to the intensity of the poison.

PROF. CORNIL stated that one cannot always maintain that a certain fluid contains no tubercle bacilli, for spores, without bacilli, may be present.

DR. HUMBERT, of Paris, presented a communication on the "Surgical Treatment of Tuberculosis of the Testicle." So soon as the diagnosis is established, an opening is made with the thermo-cautery and all tuberculous structure is removed with the curette. In the great majority of cases castration is followed by a generalization of the tuberculosis, while it is well known that in most cases castration of one testicle for tuberculosis is followed by involvement of the other, necessitating double castration.

PROF. VERNEUIL stated that twenty years ago he condemned castration for tuberculosis of the testicle. Almost always, soon after the operation generalization of the tuberculosis occurs. In eighty cases of a hundred one cannot expect to remove the bacillary focus, for if a rectal examination is made the prostate gland and seminal vesicles will be found to be tuberculous.

DR. PETIT read a note in the name of DR. TUFFIER, giving the history of four cases of tuberculous hydroceles, the liquid of which did not indicate the presence of the tubercle bacillus; its tuberculous nature was established by the development of tuberculosis in an inoculated guinea-pig.

MM. COURMONT and DOR, of Lyon, presented a communication on "Anti-tuberculous Vaccination with Soluble Products Obtained from the Bacillus of Bird-Tuberculosis." Liquid cultures of the bacillus of bird-tuberculosis, filtered through porcelain, were injected subcutaneously, intra-venously, and intra-peritoneally, into guinea-pigs and rabbits. The results obtained, so far as toxic effects are concerned, were negative when the filtered culture had been previously attenuated; toxic effects developed when the filtered culture was left virulent. In about 75 per cent. of inoculated rabbits infection was postponed, and instead of observing rapid death and the usual lesions, only well-formed tubercles were found; in about 25 per cent. of cases the influence of vaccination was still more apparent, animals surviving enormous doses of virus, those sacrificed several months after the injection presenting not a trace of tuberculous infection. In four cases rabbits that had resisted bird-tuberculosis were inoculated seven months later with a very virulent form of human tuberculosis, and presented no sign of the disease. Guinea-pigs can only be satisfactorily vaccinated by intra-venous inoculation, but, on the other hand, they are much more sensitive to the toxic action of the vaccine employed.

DR. MARFAN, of Paris, presented a communication upon "New Researches on the Gastric Disturbances and Lesions Encountered in Pulmonary Tuberculosis." He makes three classes of the disease: 1st, the common dyspepsia of phthisical patients; 2, the initial forms of this dyspepsia; 3, the terminal gastritis.

Under the head of common dyspepsia we find a series of disturbances, such as a diminution in the appetite, fetid or acid gastric eructations following the taking of food; gastric cough, from food coming in contact with the gastric mucous membrane, and finally vomiting; the vomiting and gastric cough are attributed to abnormal irritability of the pneumogastric nerve. The other gastric symptoms are dependent upon enfeeblement of the muscular coats of the stomach and dilatation of the organ; or to a diluted gastric juice, with or without putrid fermentations. The weakened condition of the motor power and of the gastric juice is ascribed to a poisoning of the walls of the stomach by tuberculous toxines; hence, phthisical dyspepsia is a toxic dyspepsia. In most cases the ordinary dyspepsia appears at once and develops with the phenomenon that announces a pulmonary localization soon afterward. In other cases the appearance of the dyspepsia is preceded by gastric symptoms of different origin, clinically characterized by more or less intense gastralgia, and chemically by a hyper-secretion and hyper-acidity of the gastric juice. This condition is often observed before the development of the tuberculous lesion and corresponds to what has been called pre-tuberculous dyspepsia. This is always accompanied by gastric dilatation, but is inconstant and

does not last long after pulmonary tuberculosis has really manifested itself, as it is replaced by a state of hypo-secretion and hypo-acidity of the common form of dyspepsia.

During the last stage of the disease, when large cavities are found in the lungs, new symptoms related to the digestive tract appear, indicating the development of gastritis. The phenomena that characterize this particular gastritis are: a bright-red tongue, of glazed appearance, deprived of its superficial layer of epithelium, as observed after scarlet fever; in addition, profound anorexia is present, and persistent diarrhea dependent upon the coexistence of intestinal lesions. This gastritis is probably due to a tuberculous intoxication, in addition to toxic infection so frequently observed in the last stages of pulmonary phthisis.

It is difficult to formulate the treatment to be recommended for such patients. The vomiting necessitates the use of the local anesthetics, among which may be placed creasote in dilute solution, cocaine, menthol, carbolic acid, or chloroform-water.

CORRESPONDENCE.

PARIS.

While at Salzburg I was struck by the fact of the large number of people suffering with goiter, those affected being chiefly women. I believe it has been ascertained that in a considerable number of cases of removal of the enlarged thyroid, mental disease follows, and hence operators of most experience are trying whether this danger may be averted by employing only partial extirpation. The question naturally suggests itself whether removal of the uterine appendages may not also be followed in many cases by similar disease. Certainly, if collected, the statistics of these operations are sufficiently numerous to give light upon this subject. Auvard, the only professional acquaintance that I have met in Paris—the few others that I know being absent upon their summer vacation—tells me that this operation is too frequently done in that city, and I think a similar belief as to its being too often done in our own country prevails with the majority of the profession in the United States. In reply to my question as to operations for pyosalpinx being so frequent in Paris, so few in Germany—in the latter I have seen but one in more than thirty abdominal sections—he stated that both septic and specific inflammation of the tubes were much more common in France than in Germany. The reason for the greater frequency of the latter was clandestine prostitution and of the former the common neglect of proper antiseptic precautions by the French midwife, while these were strictly observed by the German.

Auvard showed me two operations—one an amputation of the vaginal cervix for retroflexion (the uterus was hypertrophied, and involution would follow, with probable restoration of the organ to its normal position); the other dilatation, curetting, and application of an iron solution for a bleeding fibroid. The last operation was the same that I had previously seen Winckel do, and illustrated a corresponding, wise conservatism. The lesson is plain: Never resort to a grave operation until milder means have proved useless. For vaginal packing he employs a gauze prepared with salol, spermaceti, and glycerin; certainly, it makes an admirable tampon, the best I have seen.

In two months his work on *Diseases of Women* will be issued, and those familiar with his treatise upon obstetrics as well as with his volumes of obstetric contributions, will look forward with pleasure to its appearance. Pozzi's work on the same subject issued last year was too large, too diffuse, and its most valuable portions seem to me to be more the teaching of Berlin than that of Paris.

After the operation Dr. Auvard was kind enough to take me to Salpêtrière, at which it was expected Térillon's assistant (Térillon himself being absent from the city) would do a hysterectomy for a rapidly-growing supposed myoma; abdominal section had been done some time before for, I believe, an ovarian tumor. The moment the abdominal cavity was opened considerable bloody serum escaped, and then there was quite a free hemorrhage. It was found impossible to remove the growth, the malignancy of which could not be doubted, and so the wound was closed, considerable iodoform gauze being pressed down toward the bleeding part and a portion of it left projecting externally, drainage thus being certainly secured and possible hemostasis promoted. I think the patient died within twenty-four hours. Following this the same operator performed a colotomy. The patient had a malignant tumor of the ovary; this had been removed, but the disease reappeared, and obstruction of the bowel followed, for which an opening had been made in the descending colon. The disease still extending, it was thought advisable to open the transverse colon, and the preparation for such opening I witnessed—that is, the abdominal incision and stitching the intestine to the abdominal wall, the opening of the intestine being deferred until adhesion had occurred. The point of greatest interest to me in the operation was that the administration of an anesthetic was believed to be contra-indicated, lest the possible straining and vomiting resulting therefrom would rupture adhesions or previous abdominal incisions; the sensibility was lessened, but by no means abolished, by the hypodermatic injection of a two per cent. solution of cocaine at four different points along the line to be incised. While the incision caused only slight suffering, the suturing of the intestine to the abdominal wall caused considerable, but not when the needle was passed through the walls of the bowel—only when the needle passed through the parietes of the abdomen.

Dr. James Henry Bennet, one of the pioneers in the local treatment of uterine diseases, has just passed away, at the age of seventy-five. So too, comparatively recently, two famous German teachers, whose contributions to obstetrics and gynecology were more important—Scanzoni, who was seventy years old, and Braun—have gone over to the majority. Great as these men were, it is vain to speak of their loss as irreparable. As the old Italian proverb has it, "With or without the cock crowing, God makes the day;" and so medicine goes on independently of the departure of individuals.

I found, when in Berlin, considerable interest in the question as to who was to be Braun's successor. When a vacancy occurs in any of the medical schools of the German Universities, the faculty present three names to

the Minister of Public Instruction, who makes the selection. Schauta, Pawlik—the third I cannot now recall—were the names proposed for Braun's place. When in Munich I learned that Schauta had been chosen, and I believe the choice is generally commended, though many would have been delighted to see that brilliant teacher and operator and genial gentleman, Pawlik, successful.

The question has suggested itself whether a somewhat similar plan might not be wisely employed in filling vacancies in our own medical schools.

But, returning from this digression, the best aseptic operating table I have ever seen was that employed by Auvard, and several similar ones by the same manufacturer, the celebrated surgical instrument-maker of Paris, Mathieu. These tables are made of steel and German silver, and are nickel-plated. Considering their material, they are not very heavy. One of the forms that Mathieu makes can be folded up and thus readily taken to the house in which an operation is to be done; another is so constructed that it may be made to revolve vertically through about one-fourth of a circle, and thus permit of instant lowering of the head in case of threatened danger from anesthesia, or, on the other hand, an elevation of the hips, so that really the Trendelenburg position is given.

By the way, the watchfulness against the danger just mentioned was shown in all of several cases that I have seen here, by the anesthetizer applying forceps to the tongue, the instrument remaining, causing partial extrusion, until the operation is over; it is hardly necessary to state that on the Continent chloroform seems the only anesthetic used.

Mathieu told me that he intended going to the Chicago Exposition and making an exhibit of instruments. I am confident that the profession will take great interest in such an exhibit. Incidentally it may be stated that the table to which I have referred costs six hundred francs ($120), irrespective of form; there are at least half a dozen patterns. It would be a good thing if every operating hospital in our country had one; there is nothing better for securing perfect cleanliness.

In regard to foreign professional visitors to Chicago, probably the number will be greater than most anticipate. More than one gentleman in Berlin told me that he was coming. It must be remembered that I met very few physicians there, except those especially devoted to obstetrics and diseases of women. Dr. Auvard is coming, and, like others, he is desirous of making his visit at the time when some of our national medical societies shall be in session, in order that he may meet as many of the profession, or at least as many of those that are engaged in his special department, as possible. Ought not the profession of the United States to take measures to secure the realization of such desire?

Herewith I conclude these hurriedly-written letters from abroad. During my visit I have seen much that was interesting, instructive, and useful to me. If through my eyes others are enabled to see anything that in even a slight degree may be useful, my labor is not in vain.

The visitor to the Mozart Museum in Salzburg will find in a glass case amid a number of the relics of the great musical composer, such as letters, jewels, miniatures painted on ivory, etc., a paper marked, in the printing of more than a century ago, "Court Plaister." This Mozart got when visiting England some years before 1800. It may be that this letter will be no more among the treasures of THE MEDICAL NEWS than that paper of "court plaister" is in the Mozart collection; but still the one, like the other, may help to close a gap, and none will gape at its close. T. P.

SELF-RETAINING PALATE RETRACTOR.

To the Editor of THE MEDICAL NEWS,

SIR: Permit me to say that the illustration of the palate retractor, published in your issue of September 5th, utterly failed to convey a proper idea of *my* instrument. By some misconception the wood-cut furnished you by my instrument-maker, and which I did not see, was not a representation of my modification, as may readily be discerned by a perusal of the article. I hope at an early day to have an accurate illustration of the instrument reproduced. T. H. WEAGLY.

MARION, PA.

NEWS ITEMS.

The American Neurological Association will hold its seventeenth annual meeting at Washington, D. C., September 22, 23, and 24, 1891.

The following program has been formulated:
